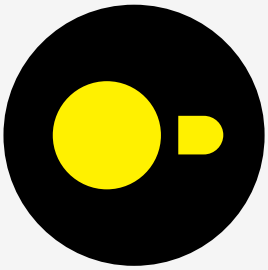
DuckDB Documentation

DuckDB version 1.5.4
Generated on 2026-06-18 at 14:30 UTC



Contents

Contents i

Summary 1

Connect 3

Connect 4

Concurrency 5

Data Import and Export 6

Importing Data 7

Data Sources 9

CSV Files 10
- CSV Import . . . 10
- CSV Auto Detection . . . 15
- Reading Faulty CSV Files . . . 19
- CSV Import Tips . . . 23

JSON Files 25
- JSON Overview . . . 25
- Creating JSON . . . 27
- Loading JSON . . . 27
- Writing JSON . . . 34
- JSON Type . . . 34
- JSON Processing Functions . . . 36
- JSON Format Settings . . . 42
- Installing and Loading the JSON Extension . . . 45
- SQL to/from JSON . . . 45
- Caveats . . . 47

Multiple Files 48
- Reading Multiple Files . . . 48
- Combining Schemas . . . 50

Parquet Files 53
- Reading and Writing Parquet Files . . . 53
- Querying Parquet Metadata . . . 58
- Parquet Encryption . . . 61
- Parquet Tips . . . 63

Partitioning 65
- Hive Partitioning . . . 65

Partitioned Writes . . . 66

Appender **69**

INSERT Statements **71**

Lakehouse Formats 72

Client APIs 75

Client Overview **76**

ADBC Client **77**

C **88**
Overview . . . 88
Startup & Shutdown . . . 88
Configuration . . . 94
Query . . . 96

Vectors . . . 106
Values . . . 120
Types . . . 143
Prepared Statements . . . 161
Appender . . . 167
Table Functions . . . 177
Replacement Scans . . . 188
Complete API . . . 190

C++ API **334**

CLI **339**
Command Line Client . . . 339
Command Line Arguments . . . 345
Dot Commands . . . 347
Output Formats . . . 354
Editing . . . 357
Friendly CLI . . . 359
Safe Mode . . . 360
Autocomplete . . . 361
Syntax Highlighting . . . 361
Known Issues . . . 363

Go Client **364**

Java (JDBC) Client **367**

Node.js (Neo) **372**
Node.js Client (Neo) . . . 372

ODBC **390**
ODBC API Overview . . . 390
ODBC API on Linux . . . 390
ODBC API on Windows . . . 391
ODBC API on macOS . . . 395

ODBC Configuration . . . 396

Python **398**
Python API . . . 398
Data Ingestion . . . 402
Conversion between DuckDB and Python . . . 404
Python DB API . . . 409
Relational API . . . 412
Python Function API . . . 537
Types API . . . 542
Expression API . . . 545
Spark API . . . 550
Python Client API . . . 551
Troubleshooting . . . 551

R Client **553**

Rust Client **557**

Wasm **559**
DuckDB Wasm . . . 559
Deploying DuckDB-Wasm . . . 559
Instantiation . . . 560
Data Ingestion . . . 562
Query . . . 565
Extensions . . . 566

Tertiary Clients **569**
Tertiary Clients . . . 569
Dart Client . . . 569
Julia Client . . . 572
PHP Client . . . 575
Swift Client . . . 578

SQL 582

SQL Introduction **583**

Statements **591**
Statements Overview . . . 591
ANALYZE Statement . . . 591
ALTER TABLE Statement . . . 591
ALTER VIEW Statement . . . 595
ATTACH and DETACH Statements . . . 596
CALL Statement . . . 600
CHECKPOINT Statement . . . 601
COMMENT ON Statement . . . 602
COPY Statement . . . 603
CREATE MACRO Statement . . . 612
CREATE SCHEMA Statement . . . 616
CREATE SECRET Statement . . . 617
CREATE SEQUENCE Statement . . . 617
CREATE TABLE Statement . . . 621
CREATE VIEW Statement . . . 625
CREATE TYPE Statement . . . 625

DELETE Statement . . . 626
DESCRIBE Statement . . . 627
DROP Statement . . . 627
EXPORT and IMPORT DATABASE Statements . . . 629
INSERT Statement . . . 630
LOAD / INSTALL Statements . . . 636
MERGE INTO Statement . . . 637
PIVOT Statement . . . 640
Profiling Queries . . . 646
SELECT Statement . . . 646
SET and RESET Statements . . . 649
SET VARIABLE and RESET VARIABLE Statements . . . 650
SHOW, SHOW DATABASES, and SHOW SCHEMAS Statements . . . 652
SUMMARIZE Statement . . . 653
Transaction Management . . . 653
UNPIVOT Statement . . . 654
UPDATE Statement . . . 660
USE Statement . . . 662
VACUUM Statement . . . 662

Query Syntax **664**
SELECT Clause . . . 664
FROM and JOIN Clauses . . . 666
WHERE Clause . . . 675
GROUP BY Clause . . . 676
GROUPING SETS . . . 677
HAVING Clause . . . 681
ORDER BY Clause . . . 681
LIMIT and OFFSET Clauses . . . 683
SAMPLE Clause . . . 684
Unnesting . . . 684
WITH Clause . . . 687
WINDOW Clause . . . 695
QUALIFY Clause . . . 695
VALUES Clause . . . 697
FILTER Clause . . . 697
Set Operations . . . 700
Prepared Statements . . . 703

Data Types **705**
Data Types . . . 705
Array Type . . . 707
Bitstring Type . . . 709
Blob Type . . . 710
Boolean Type . . . 710
Date Types . . . 711
Enum Data Type . . . 712
Geometry Data Type . . . 716
Interval Type . . . 723
List Type . . . 726
Literal Types . . . 728
Map Type . . . 731
NULL Values . . . 732
Numeric Types . . . 734

Struct Data Type . . . 737
Text Types . . . 742
Time Types . . . 743
Timestamp Types . . . 744
Time Zone Reference List . . . 749
Union Type . . . 766
Typecasting . . . 768
Variant Type . . . 772

Expressions **775**
Expressions . . . 775
CASE Expression . . . 775
Casting . . . 777
Collations . . . 778
Comparisons . . . 781
IN Operator . . . 782
Logical Operators . . . 783
Star Expression . . . 784
Subqueries . . . 789
TRY Expression . . . 793

Functions **795**
Functions . . . 795
Aggregate Functions . . . 796
Array Functions . . . 811
Bitstring Functions . . . 813
Blob Functions . . . 816
Date Format Functions . . . 819
Date Functions . . . 822
Date Part Functions . . . 826
Enum Functions . . . 833
Geometry Functions . . . 834
Interval Functions . . . 836
Lambda Functions . . . 839
List Functions . . . 844
Map Functions . . . 869
Nested Functions . . . 872
Numeric Functions . . . 872
Pattern Matching . . . 883
Regular Expressions . . . 887
Struct Functions . . . 891
Text Functions . . . 894
Time Functions . . . 918
Timestamp Functions . . . 920
Timestamp with Time Zone Functions . . . 928
Union Functions . . . 938
Utility Functions . . . 939
Window Functions . . . 950

Constraints **961**

Indexes **964**

Meta Queries **966**

Summary

This document contains DuckDB's official documentation and guides in a single-file easy-to-search form. If you find any issues, please report them as a GitHub issue. Contributions are very welcome in the form of pull requests. If you are considering submitting a contribution to the documentation, please consult our contributor guide.

Code repositories:

- DuckDB documentation source code: github.com/duckdb/duckdb-web

Connect

Connect

Connect or Create a Database

To use DuckDB, you must first create a connection to a database. The exact syntax varies between the client APIs but it typically involves passing an argument to configure persistence.

Persistence

DuckDB can operate in both persistent mode, where the data is saved to disk, and in in-memory mode, where the entire dataset is stored in the main memory.

> **Tip.** Both persistent and in-memory databases use spilling to disk to facilitate larger-than-memory workloads (i.e., out-of-core-processing).

Persistent Database

To create or open a persistent database, set the path of the database file, e.g., `my_database.duckdb`, when creating the connection. This path can point to an existing database or to a file that does not yet exist and DuckDB will open or create a database at that location as needed. The file may have an arbitrary extension, but `.db` or `.duckdb` are two common choices with `.ddb` also used sometimes.

Starting with v0.10, DuckDB's storage format is backwards-compatible, i.e., DuckDB is able to read database files produced by an older version of DuckDB. For example, DuckDB v0.10 can read and operate on files created by the previous DuckDB version, v0.9. For more details on DuckDB's storage format, see the storage page.

In-Memory Database

DuckDB can operate in in-memory mode. In most clients, this can be activated by passing the special value `:memory:` as the database file or omitting the database file argument. In in-memory mode, no data is persisted to disk, therefore, all data is lost when the process finishes.

Concurrency

Handling Concurrency

Single Process

In in-process mode, DuckDB has two configurable options for concurrency:

1. **Read-write mode:** one process can both read and write to the database.
2. **Read-only mode:** multiple processes can read from the database, but no processes can write (`access_mode = 'READ_ONLY'`).

When using read-write mode, DuckDB supports multiple writer threads using a combination of MVCC (Multi-Version Concurrency Control) and optimistic concurrency control (see Concurrency within a Single Process), but all within that single writer process. The reason for this concurrency model is to allow for the caching of data in RAM for faster analytical queries, rather than going back and forth to disk during each query. It also allows the caching of function pointers, the database catalog, and other items so that subsequent queries on the same connection are faster.

Concurrency Model within a Single Process DuckDB supports concurrency within a single process according to the following rules. As long as there are no write conflicts, multiple concurrent writes will succeed. Appends will never conflict, even on the same table. Multiple threads can also simultaneously update separate tables or separate subsets of the same table. Optimistic concurrency control comes into play when two threads attempt to edit (update or delete) the same row at the same time. In that situation, the second thread to attempt the edit will fail with a conflict error.

Multiple Processes

Writing to DuckDB's native database format from multiple processes is supported through the Quack remote protocol, which turns DuckDB into a client-server database. Quack in beta stage as of DuckDB v1.5.2, and is expected to become mature by DuckDB v2.0 in fall 2026.

For a stable solution, consider using the DuckLake format with PostgreSQL as the catalog database. By coordinating through a central PostgreSQL catalog, DuckDB instances can achieve concurrent read-writes on the same database. The DuckLake v1.0 specification and its DuckDB implementation, both intended for production use, were published in April 2026.

Optimistic Concurrency Control

DuckDB uses optimistic concurrency control, an approach generally considered to be the best fit for read-intensive analytical database systems as it speeds up read query processing. As a result any transactions that modify the same rows at the same time will cause a transaction conflict error:

```
Transaction conflict: cannot update a table that has been altered!
```

> **Tip.** A common workaround when a transaction conflict is encountered is to rerun the transaction.

Troubleshooting

File locks. DuckDB handles concurrent database access requests using file locks. Exercise extra caution when accessing a DuckDB database file in a shared directory (e.g., from different operating systems using different file systems or on network attached storage).

Data Import and Export

Importing Data

The first step to using a database system is to insert data into that system. DuckDB can directly connect to many popular data sources and offers several data ingestion methods that allow you to easily and efficiently fill up the database. On this page, we provide an overview of these methods so you can select which one is best suited for your use case.

`INSERT` Statements

`INSERT` statements are the standard way of loading data into a database system. They are suitable for quick prototyping, but should be avoided for bulk loading as they have significant per-row overhead.

```
INSERT INTO people VALUES (1, 'Mark');
```

For a more detailed description, see the page on the `INSERT` statement.

File Loading: Relative Paths

Use the configuration option `file_search_path` to configure to which "root directories" relative paths are expanded on. If `file_search_path` is not set, the working directory is used as the basis for relative paths.

File Formats

CSV Loading

Data can be efficiently loaded from CSV files using several methods. The simplest is to use the CSV file's name:

```
SELECT * FROM 'test.csv';
```

Alternatively, use the `read_csv` function to pass along options:

```
SELECT * FROM read_csv('test.csv', header = false);
```

Or use the COPY statement:

```
COPY tbl FROM 'test.csv' (HEADER false);
```

It is also possible to read data directly from **compressed CSV files** (e.g., compressed with gzip):

```
SELECT * FROM 'test.csv.gz';
```

DuckDB can create a table from the loaded data using the `CREATE TABLE ... AS SELECT` statement:

```
CREATE TABLE test AS
    SELECT * FROM 'test.csv';
```

For more details, see the page on CSV loading.

Parquet Loading

Parquet files can be efficiently loaded and queried using their filename:

```
SELECT * FROM 'test.parquet';
```

Alternatively, use the `read_parquet` function:

```
SELECT * FROM read_parquet('test.parquet');
```

Or use the COPY statement:

```
COPY tbl FROM 'test.parquet';
```

For more details, see the page on Parquet loading.

JSON Loading

JSON files can be efficiently loaded and queried using their filename:

```
SELECT * FROM 'test.json';
```

Alternatively, use the `read_json` function:

```
SELECT * FROM read_json('test.json');
```

Or use the COPY statement:

```
COPY tbl FROM 'test.json';
```

For more details, see the page on JSON loading.

Returning the Filename

Since DuckDB v1.3.0, the CSV, JSON and Parquet readers support the `filename` virtual column:

```
COPY (FROM (VALUES (42), (43)) t(x)) TO 'test.parquet';
SELECT *, filename FROM 'test.parquet';
```

Appender

In several APIs (C, C++, Go, Java and Rust), the Appender can be used as an alternative for bulk data loading. This class can be used to efficiently add rows to the database system without using SQL statements.

Data Sources

DuckDB supports several data sources, including file formats, network protocols, and database systems:

- AWS S3 buckets and storage with S3-compatible API
- Azure Blob Storage
- Blob files
- Cloudflare R2
- CSV
- Delta Lake
- DuckLake
- Excel
- httpfs
- Iceberg
- JSON
- Lance tables
- MySQL
- Parquet
- PostgreSQL
- SQLite
- Text files
- Vortex files

CSV Files

CSV Import

Examples

The following examples use the `flights.csv` file.

Read a CSV file from disk, auto-infer options:

```
SELECT * FROM 'flights.csv';
```

Use the `read_csv` function with custom options:

```
SELECT *
FROM read_csv('flights.csv',
    delim = '|',
    header = true,
    columns = {
        'FlightDate': 'DATE',
        'UniqueCarrier': 'VARCHAR',
        'OriginCityName': 'VARCHAR',
        'DestCityName': 'VARCHAR'
    });
```

Read a CSV from stdin, auto-infer options:

```
cat flights.csv | duckdb -c "SELECT * FROM read_csv('/dev/stdin')"
```

Read a CSV file into a table:

```
CREATE TABLE ontime (
    FlightDate DATE,
    UniqueCarrier VARCHAR,
    OriginCityName VARCHAR,
    DestCityName VARCHAR
);
COPY ontime FROM 'flights.csv';
```

Alternatively, create a table without specifying the schema manually using a `CREATE TABLE ... AS SELECT` statement:

```
CREATE TABLE ontime AS
    SELECT * FROM 'flights.csv';
```

We can use the FROM-first syntax to omit `SELECT *`.

```
CREATE TABLE ontime AS
    FROM 'flights.csv';
```

CSV Loading

CSV loading, i.e., importing CSV files to the database, is a very common, and yet surprisingly tricky, task. While CSVs seem simple on the surface, there are a lot of inconsistencies found within CSV files that can make loading them a challenge. CSV files come in many different varieties, are often corrupt, and do not have a schema. The CSV reader needs to cope with all of these different situations.

The DuckDB CSV reader can automatically infer which configuration flags to use by analyzing the CSV file using the CSV sniffer. This will work correctly in most situations, and should be the first option attempted. In rare situations where the CSV reader cannot figure out the correct configuration it is possible to manually configure the CSV reader to correctly parse the CSV file. See the auto detection page for more information.

Parameters

Below are parameters that can be passed to the `read_csv` function. Where meaningfully applicable, these parameters can also be passed to the `COPY` statement.

Name	Description	Type	Default
`all_varchar`	Skip type detection and assume all columns are of type `VARCHAR`. This option is only supported by the `read_csv` function.	`BOOL`	`false`
`allow_quoted_nulls`	Allow the conversion of quoted values to `NULL` values	`BOOL`	`true`
`auto_detect`	Auto detect CSV parameters.	`BOOL`	`true`
`auto_type_candidates`	Types that the sniffer uses when detecting column types. The `VARCHAR` type is always included as a fallback option. See example.	`TYPE[]`	default types
`buffer_size`	Size of the buffers used to read files, in bytes. Must be large enough to hold four lines and can significantly impact performance.	`BIGINT`	`16 * max_line_size`
`columns`	Column names and types, as a struct (e.g., `{'col1': 'INTEGER', 'col2': 'VARCHAR'}`). Using this option disables auto detection of the schema.	`STRUCT`	(empty)
`comment`	Character used to initiate comments. Lines starting with a comment character (optionally preceded by space characters) are completely ignored; other lines containing a comment character are parsed only up to that point.	`VARCHAR`	(empty)
`compression`	Method used to compress CSV files. By default this is detected automatically from the file extension (e.g., `t.csv.gz` will use gzip, `t.csv` will use none). Options are `none`, `gzip`, `zstd`.	`VARCHAR`	`auto`
`dateformat`	Date format used when parsing and writing dates.	`VARCHAR`	(empty)
`date_format`	Alias for `dateformat`; only available in the `COPY` statement.	`VARCHAR`	(empty)
`decimal_separator`	Decimal separator for numbers.	`VARCHAR`	`.`
`delim`	Delimiter character used to separate columns within each line, e.g., `,` `;` `\t`. The delimiter character can be up to 4 bytes, e.g., 🦆. Alias for `sep`.	`VARCHAR`	`,`
`delimiter`	Alias for `delim`; only available in the `COPY` statement.	`VARCHAR`	`,`
`escape`	String used to escape the `quote` character within quoted values.	`VARCHAR`	`"`
`encoding`	Encoding used by the CSV file. Options are `utf-8`, `utf-16`, `latin-1`. Not available in the `COPY` statement (which always uses `utf-8`).	`VARCHAR`	`utf-8`

Name	Description	Type	Default
`filename`	Add path of the containing file to each row, as a string column named `filename`. Relative or absolute paths are returned depending on the path or glob pattern provided to `read_csv`, not just filenames. Since DuckDB v1.3.0, the `filename` column is added automatically as a virtual column and this option is only kept for compatibility reasons.	`BOOL`	`false`
`files_to_sniff`	Number of files used by the CSV sniffer to detect the schema when reading multiple files. Set to `-1` to sniff all files.	`BIGINT`	`10`
`force_not_null`	Do not match values in the specified columns against the `NULL` string. In the default case where the `NULL` string is empty, this means that empty values are read as zero-length strings instead of `NULL`s.	`VARCHAR[]`	`[]`
`header`	First line of each file contains the column names.	`BOOL`	`false`
`hive_partitioning`	Interpret the path as a Hive partitioned path.	`BOOL`	(auto-detected)
`ignore_errors`	Ignore any parsing errors encountered.	`BOOL`	`false`
`max_line_size` or `maximum_line_size`. Not available in the COPY statement.	Maximum line size, in bytes.	`BIGINT`	2000000
`names` or `column_names`	Column names, as a list. See example.	`VARCHAR[]`	(empty)
`new_line`	New line character(s). Options are `'\r'`,`'\n'`, or `'\r\n'`. The CSV parser only distinguishes between single-character and double-character line delimiters. Therefore, it does not differentiate between `'\r'` and `'\n'`.	`VARCHAR`	(empty)
`normalize_names`	Normalize column names. This removes any non-alphanumeric characters from them. Column names that are reserved SQL keywords are prefixed with an underscore character (_).	`BOOL`	`false`
`null_padding`	Pad the remaining columns on the right with `NULL` values when a line lacks columns.	`BOOL`	`false`
`nullstr` or `null`	Strings that represent a `NULL` value.	`VARCHAR` or `VARCHAR[]`	(empty)
`parallel`	Use the parallel CSV reader.	`BOOL`	`true`
`quote`	String used to quote values.	`VARCHAR`	`"`
`rejects_scan`	Name of the temporary table where information on faulty scans is stored.	`VARCHAR`	`reject_scans`
`rejects_table`	Name of the temporary table where information on faulty lines is stored.	`VARCHAR`	`reject_errors`
`rejects_limit`	Upper limit on the number of faulty lines per file that are recorded in the rejects table. Setting this to `0` means that no limit is applied.	`BIGINT`	`0`
`sample_size`	Number of sample lines for auto detection of parameters.	`BIGINT`	20480

Name	Description	Type	Default
`sep`	Delimiter character used to separate columns within each line, e.g., `,` `;` `\t`. The delimiter character can be up to 4 bytes, e.g., 🦆. Alias for `delim`.	VARCHAR	`,`
`skip`	Number of lines to skip at the start of each file.	BIGINT	0
`store_rejects`	Skip any lines with errors and store them in the rejects table.	BOOL	`false`
`strict_mode`	Enforces the strictness level of the CSV Reader. When set to `true`, the parser will throw an error upon encountering any issues. When set to `false`, the parser will attempt to read structurally incorrect files. It is important to note that reading structurally incorrect files can cause ambiguity; therefore, this option should be used with caution.	BOOL	`true`
`thousands`	Character used to identify thousands separators in numeric values. It must be a single character and different from the `decimal_separator` option.	VARCHAR	(empty)
`timestampformat`	Timestamp format used when parsing and writing timestamps.	VARCHAR	(empty)
`timestamp_format`	Alias for `timestampformat`; only available in the COPY statement.	VARCHAR	(empty)
`types` or `dtypes` or `column_types`	Column types, as either a list (by position) or a struct (by name). See example.	VARCHAR`[]` or STRUCT	(empty)
`union_by_name`	Align columns from different files by column name instead of position. Using this option increases memory consumption.	BOOL	`false`

> **Tip.** DuckDB's CSV reader supports `UTF-8` (default), `UTF-16` and `Latin-1` encodings. For other encodings, you can either use the `encodings` extension or convert them e.g. using the `iconv` command-line tool:
>
> ```
> iconv -f ISO-8859-2 -t UTF-8 input.csv > input-utf-8.csv
> ```

`auto_type_candidates` Details

The `auto_type_candidates` option lets you specify the data types that should be considered by the CSV reader for column data type detection. Usage example:

```
SELECT * FROM read_csv('csv_file.csv', auto_type_candidates = ['BIGINT', 'DATE']);
```

The default value for the `auto_type_candidates` option is `['NULL', 'BOOLEAN', 'BIGINT', 'DOUBLE', 'TIME', 'DATE', 'TIMESTAMP', 'VARCHAR']`.

CSV Functions

The `read_csv` automatically attempts to figure out the correct configuration of the CSV reader using the CSV sniffer. It also automatically deduces types of columns. If the CSV file has a header, it will use the names found in that header to name the columns. Otherwise, the columns will be named `column0, column1, column2, ...`. An example with the `flights.csv` file:

```
SELECT * FROM read_csv('flights.csv');
```

FlightDate	UniqueCarrier	OriginCityName	DestCityName
1988-01-01	AA	New York, NY	Los Angeles, CA
1988-01-02	AA	New York, NY	Los Angeles, CA
1988-01-03	AA	New York, NY	Los Angeles, CA

The path can either be a relative path (relative to the current working directory) or an absolute path.

We can use `read_csv` to create a persistent table as well:

```
CREATE TABLE ontime AS
    SELECT * FROM read_csv('flights.csv');
DESCRIBE ontime;
```

column_name	column_type	null	key	default	extra
FlightDate	DATE	YES	NULL	NULL	NULL
UniqueCarrier	VARCHAR	YES	NULL	NULL	NULL
OriginCityName	VARCHAR	YES	NULL	NULL	NULL
DestCityName	VARCHAR	YES	NULL	NULL	NULL

```
SELECT * FROM read_csv('flights.csv', sample_size = 20_000);
```

If we set `delim` / `sep`, `quote`, `escape`, or `header` explicitly, we can bypass the automatic detection of this particular parameter:

```
SELECT * FROM read_csv('flights.csv', header = true);
```

Multiple files can be read at once by providing a glob or a list of files. Refer to the multiple files section for more information.

Writing Using the COPY Statement

The COPY statement can be used to load data from a CSV file into a table. This statement has the same syntax as the one used in PostgreSQL. To load the data using the COPY statement, we must first create a table with the correct schema (which matches the order of the columns in the CSV file and uses types that fit the values in the CSV file). COPY detects the CSV's configuration options automatically.

```
CREATE TABLE ontime (
    flightdate DATE,
    uniquecarrier VARCHAR,
    origincityname VARCHAR,
    destcityname VARCHAR
);
COPY ontime FROM 'flights.csv';
SELECT * FROM ontime;
```

flightdate	uniquecarrier	origincityname	destcityname
1988-01-01	AA	New York, NY	Los Angeles, CA
1988-01-02	AA	New York, NY	Los Angeles, CA
1988-01-03	AA	New York, NY	Los Angeles, CA

If we want to manually specify the CSV format, we can do so using the configuration options of COPY.

```
CREATE TABLE ontime (flightdate DATE, uniquecarrier VARCHAR, origincityname VARCHAR, destcityname
VARCHAR);
COPY ontime FROM 'flights.csv' (DELIMITER '|', HEADER);
SELECT * FROM ontime;
```

Reading Faulty CSV Files

DuckDB supports reading erroneous CSV files. For details, see the Reading Faulty CSV Files page.

Order Preservation

The CSV reader respects the `preserve_insertion_order` configuration option to preserve insertion order. When `true` (the default), the order of the rows in the result set returned by the CSV reader is the same as the order of the corresponding lines read from the file(s). When `false`, there is no guarantee that the order is preserved.

Writing CSV Files

DuckDB can write CSV files using the `COPY ... TO` statement.

CSV Auto Detection

When using `read_csv`, the system tries to automatically infer how to read the CSV file using the CSV sniffer. This step is necessary because CSV files are not self-describing and come in many different dialects. The auto-detection works roughly as follows:

- Detect the dialect of the CSV file (delimiter, quoting rule, escape).
- Detect the types of each of the columns.
- Detect whether or not the file has a header row.

By default the system will try to auto-detect all options. However, options can be individually overridden by the user. This can be useful in case the system makes a mistake. For example, if the delimiter is chosen incorrectly, we can override it by calling the `read_csv` with an explicit delimiter (e.g., `read_csv('file.csv', delim = '|')`).

Sample Size

The type detection works by operating on a sample of the file. The size of the sample can be modified by setting the `sample_size` parameter. The default sample size is 20,480 rows. Setting the `sample_size` parameter to `-1` means the entire file is read for sampling:

```
SELECT * FROM read_csv('my_csv_file.csv', sample_size = -1);
```

The way sampling is performed depends on the type of file. If we are reading from a regular file on disk, we will jump into the file and try to sample from different locations in the file. If we are reading from a file in which we cannot jump – such as a `.gz` compressed CSV file or `stdin` – samples are taken only from the beginning of the file.

`sniff_csv` Function

It is possible to run the CSV sniffer as a separate step using the `sniff_csv(filename)` function, which returns the detected CSV properties as a table with a single row. The `sniff_csv` function accepts an optional `sample_size` parameter to configure the number of rows sampled.

```
FROM sniff_csv('my_file.csv');
FROM sniff_csv('my_file.csv', sample_size = 1000);
```

Column name	Description	Example
`Delimiter`	Delimiter	`,`
`Quote`	Quote character	`"`
`Escape`	Escape	`\`
`NewLineDelimiter`	New-line delimiter	`\r\n`
`Comment`	Comment character	`#`
`SkipRows`	Number of rows skipped	`1`
`HasHeader`	Whether the CSV has a header	`true`
`Columns`	Column types encoded as a `LIST` of `STRUCT`s	`({'name': 'VARCHAR', 'age': 'BIGINT'})`
`DateFormat`	Date format	`%d/%m/%Y`
`TimestampFormat`	Timestamp Format	`%Y-%m-%dT%H:%M:%S.%f`
`UserArguments`	Arguments used to invoke `sniff_csv`	`sample_size = 1000`
`Prompt`	Prompt ready to be used to read the CSV	`FROM read_csv('my_file.csv', auto_detect=false, delim=',', ...)`

Prompt

The `Prompt` column contains a SQL command with the configurations detected by the sniffer.

```
-- use line mode in CLI to get the full command
.mode line
SELECT Prompt FROM sniff_csv('my_file.csv');
```

```
Prompt = FROM read_csv('my_file.csv', auto_detect=false, delim=',', quote='"', escape='"', new_
line='\n', skip=0, header=true, columns={...});
```

Detection Steps

Dialect Detection

Dialect detection works by attempting to parse the samples using the set of considered values. The detected dialect is the dialect that has (1) a consistent number of columns for each row, and (2) the highest number of columns for each row.

The following dialects are considered for automatic dialect detection.

Parameters	Considered values
`delim`	`,` `|` `;` `\t`
`quote`	`"` `'` (empty)
`escape`	`"` `'` `\` (empty)

Consider the example file `flights.csv`:

```
FlightDate|UniqueCarrier|OriginCityName|DestCityName
1988-01-01|AA|New York, NY|Los Angeles, CA
1988-01-02|AA|New York, NY|Los Angeles, CA
1988-01-03|AA|New York, NY|Los Angeles, CA
```

In this file, the dialect detection works as follows:

- If we split by a `|` every row is split into 4 columns.
- If we split by a `,` rows 2-4 are split into 3 columns, while the first row is split into 1 column.
- If we split by `;`, every row is split into 1 column.
- If we split by `\t`, every row is split into 1 column.

In this example – the system selects the `|` as the delimiter. All rows are split into the same amount of columns, and there is more than one column per row meaning the delimiter was actually found in the CSV file.

Type Detection

After detecting the dialect, the system will attempt to figure out the types of each of the columns. Note that this step is only performed if we are calling `read_csv`. In case of the COPY statement the types of the table that we are copying into will be used instead.

The type detection works by attempting to convert the values in each column to the candidate types. If the conversion is unsuccessful, the candidate type is removed from the set of candidate types for that column. After all samples have been handled – the remaining candidate type with the highest priority is chosen. The default set of candidate types is given below, in order of priority:

Types
NULL
BOOLEAN
TIME
DATE
TIMESTAMP
TIMESTAMPTZ
BIGINT
DOUBLE
VARCHAR

Everything can be cast to VARCHAR, therefore, this type has the lowest priority meaning that all columns are converted to VARCHAR as a fallback if they cannot be cast to anything else. In `flights.csv` the `FlightDate` column will be cast to a DATE, while the other columns will be cast to VARCHAR.

The set of candidate types that should be considered by the CSV reader can be specified explicitly using the `auto_type_candidates` option. VARCHAR as the fallback type will always be considered as a candidate type whether you specify it or not.

Here are all additional candidate types that may be specified using the `auto_type_candidates` option, in order of priority:

Types
TINYINT
SMALLINT
INTEGER
DECIMAL
FLOAT

Even though the set of data types that can be automatically detected may appear quite limited, the CSV reader can be configured to read arbitrarily complex types by using the `types`-option described in the next section.

Type detection can be entirely disabled by using the `all_varchar` option. If this is set all columns will remain as VARCHAR (as they originally occur in the CSV file).

Note that using quote characters vs. no quote characters (e.g., `"42"` and `42`) does not make a difference for type detection. Quoted fields will not be converted to VARCHAR, instead, the sniffer will try to find the type candidate with the highest priority.

Overriding Type Detection The detected types can be individually overridden using the `types` option. This option takes either of two options:

- A list of type definitions (e.g., `types = ['INTEGER', 'VARCHAR', 'DATE']`). This overrides the types of the columns in-order of occurrence in the CSV file.
- Alternatively, `types` takes a `name` → `type` map which overrides options of individual columns (e.g., `types = {'quarter': 'INTEGER'}`).

The set of column types that may be specified using the `types` option is not as limited as the types available for the `auto_type_candidates` option: any valid type definition is acceptable to the `types`-option. (To get a valid type definition, use the `typeof()` function, or use the `column_type` column of the `DESCRIBE` result.)

The `sniff_csv()` function's `Column` field returns a struct with column names and types that can be used as a basis for overriding types.

Header Detection

Header detection works by checking if the candidate header row deviates from the other rows in the file in terms of types. For example, in `flights.csv`, we can see that the header row consists of only VARCHAR columns – whereas the values contain a `DATE` value for the `FlightDate` column. As such – the system defines the first row as the header row and extracts the column names from the header row.

In files that do not have a header row, the column names are generated as `column0`, `column1`, etc.

Note that headers cannot be detected correctly if all columns are of type VARCHAR – as in this case the system cannot distinguish the header row from the other rows in the file. In this case, the system assumes the file has a header. This can be overridden by setting the `header` option to `false`.

Dates and Timestamps

DuckDB supports the ISO 8601 format by default for timestamps, dates and times. Unfortunately, not all dates and times are formatted using this standard. For that reason, the CSV reader also supports the `dateformat` and `timestampformat` options. Using this format the user can specify a format string that specifies how the date or timestamp should be read.

As part of the auto-detection, the system tries to figure out if dates and times are stored in a different representation. This is not always possible – as there are ambiguities in the representation. For example, the date `01-02-2000` can be parsed as either January 2nd or February 1st. Often these ambiguities can be resolved. For example, if we later encounter the date `21-02-2000` then we know that the format must have been `DD-MM-YYYY`. `MM-DD-YYYY` is no longer possible as there is no 21st month.

If the ambiguities cannot be resolved by looking at the data the system has a list of preferences for which date format to use. If the system chooses incorrectly, the user can specify the `dateformat` and `timestampformat` options manually.

The system considers the following formats for dates (`dateformat`). Higher entries are chosen over lower entries in case of ambiguities (i.e., ISO 8601 is preferred over `MM-DD-YYYY`).

dateformat
ISO 8601
%y-%m-%d
%Y-%m-%d

dateformat
%d-%m-%y
%d-%m-%Y
%m-%d-%y
%m-%d-%Y

The system considers the following formats for timestamps (`timestampformat`). Higher entries are chosen over lower entries in case of ambiguities.

timestampformat
ISO 8601
%y-%m-%d %H:%M:%S
%Y-%m-%d %H:%M:%S
%d-%m-%y %H:%M:%S
%d-%m-%Y %H:%M:%S
%m-%d-%y %I:%M:%S %p
%m-%d-%Y %I:%M:%S %p
%Y-%m-%d %H:%M:%S.%f

Reading Faulty CSV Files

CSV files can come in all shapes and forms, with some presenting many errors that make the process of cleanly reading them inherently difficult. To help users read these files, DuckDB supports detailed error messages, the ability to skip faulty lines and the possibility of storing faulty lines in a temporary table to assist users with a data cleaning step.

Structural Errors

DuckDB supports the detection and skipping of several different structural errors. In this section, we will go over each error with an example. For the examples, consider the following table:

```
CREATE TABLE people (name VARCHAR, birth_date DATE);
```

DuckDB detects the following error types:

- `CAST`: Casting errors occur when a column in the CSV file cannot be cast to the expected schema value. For example, the line `Pedro,The 90s` would cause an error since the string `The 90s` cannot be cast to a date.
- `MISSING COLUMNS`: This error occurs if a line in the CSV file has fewer columns than expected. In our example, we expect two columns; therefore, a row with just one value, e.g., `Pedro`, would cause this error.
- `TOO MANY COLUMNS`: This error occurs if a line in the CSV has more columns than expected. In our example, any line with more than two columns would cause this error, e.g., `Pedro,01-01-1992,pdet`.
- `UNQUOTED VALUE`: Quoted values in CSV lines must always be unquoted at the end; if a quoted value remains quoted throughout, it will cause an error. For example, assuming our scanner uses `quote='"'`, the line `"pedro"holanda, 01-01-1992` would present an unquoted value error.
- `LINE SIZE OVER MAXIMUM`: DuckDB has a parameter that sets the maximum line size a CSV file can have, which by default is set to 2,097,152 bytes. Assuming our scanner is set to `max_line_size = 25`, the line `Pedro Holanda, 01-01-1992` would produce an error, as it exceeds 25 bytes.

- `INVALID ENCODING`: DuckDB supports UTF-8 strings, UTF-16 and Latin-1 encodings. Lines containing other characters will produce an error. For example, the line `pedro\xff\xff, 01-01-1992` would be problematic.

Anatomy of a CSV Error

By default, when performing a CSV read, if any structural errors are encountered, the scanner will immediately stop the scanning process and throw the error to the user. These errors are designed to provide as much information as possible to allow users to evaluate them directly in their CSV file.

This is an example for a full error message:

```
Conversion Error:
CSV Error on Line: 5648
Original Line: Pedro,The 90s
Error when converting column "birth_date". date field value out of range: "The 90s", expected format is
(DD-MM-YYYY)

Column date is being converted as type DATE
This type was auto-detected from the CSV file.
Possible solutions:
* Override the type for this column manually by setting the type explicitly, e.g., types={'birth_date':
'VARCHAR'}
* Set the sample size to a larger value to enable the auto-detection to scan more values, e.g., sample_
size=-1
* Use a COPY statement to automatically derive types from an existing table.

  file= people.csv
  delimiter = , (Auto-Detected)
  quote = " (Auto-Detected)
  escape = " (Auto-Detected)
  new_line = \r\n (Auto-Detected)
  header = true (Auto-Detected)
  skip_rows = 0 (Auto-Detected)
  date_format = (DD-MM-YYYY) (Auto-Detected)
  timestamp_format =  (Auto-Detected)
  null_padding=0
  sample_size=20480
  ignore_errors=false
  all_varchar=0
```

The first block provides us with information regarding where the error occurred, including the line number, the original CSV line and which field was problematic:

```
Conversion Error:
CSV Error on Line: 5648
Original Line: Pedro,The 90s
Error when converting column "birth_date". date field value out of range: "The 90s", expected format is
(DD-MM-YYYY)
```

The second block provides us with potential solutions:

```
Column date is being converted as type DATE
This type was auto-detected from the CSV file.
Possible solutions:
* Override the type for this column manually by setting the type explicitly, e.g., types={'birth_date':
'VARCHAR'}
* Set the sample size to a larger value to enable the auto-detection to scan more values, e.g., sample_
size=-1
* Use a COPY statement to automatically derive types from an existing table.
```

Since the type of this field was auto-detected, it suggests defining the field as a VARCHAR or fully utilizing the dataset for type detection.

Finally, the last block presents some of the options used in the scanner that can cause errors, indicating whether they were auto-detected or manually set by the user.

Using the `ignore_errors` Option

There are cases where CSV files may have multiple structural errors, and users simply wish to skip these and read the correct data. Reading erroneous CSV files is possible by utilizing the `ignore_errors` option. With this option set, rows containing data that would otherwise cause the CSV parser to generate an error will be ignored. In our example, we will demonstrate a CAST error, but note that any of the errors described in our Structural Error section would cause the faulty line to be skipped.

For example, consider the following CSV file, `faulty.csv`:

```
Pedro,31
Oogie Boogie, three
```

If you read the CSV file, specifying that the first column is a VARCHAR and the second column is an `INTEGER`, loading the file would fail, as the string `three` cannot be converted to an `INTEGER`.

For example, the following query will throw a casting error.

```
FROM read_csv('faulty.csv', columns = {'name': 'VARCHAR', 'age': 'INTEGER'});
```

However, with `ignore_errors` set, the second row of the file is skipped, outputting only the complete first row. For example:

```
FROM read_csv(
    'faulty.csv',
    columns = {'name': 'VARCHAR', 'age': 'INTEGER'},
    ignore_errors = true
);
```

Outputs:

name	age
Pedro	31

One should note that the CSV Parser is affected by the projection pushdown optimization. Hence, if we were to select only the name column, both rows would be considered valid, as the casting error on the age would never occur. For example:

```
SELECT name
FROM read_csv('faulty.csv', columns = {'name': 'VARCHAR', 'age': 'INTEGER'});
```

Outputs:

name
Pedro
Oogie Boogie

Retrieving Faulty CSV Lines

Being able to read faulty CSV files is important, but for many data cleaning operations, it is also necessary to know exactly which lines are corrupted and what errors the parser discovered on them. For scenarios like these, it is possible to use DuckDB's CSV Rejects Table feature. By default, this feature creates two temporary tables.

1. `reject_scans`: Stores information regarding the parameters of the CSV Scanner.
2. `reject_errors`: Stores information regarding each CSV faulty line and in which CSV Scanner they happened.

Note that any of the errors described in our Structural Error section will be stored in the rejects tables. Also, if a line has multiple errors, multiple entries will be stored for the same line, one for each error.

Reject Scans

The CSV Reject Scans Table returns the following information:

Column name	Description	Type
`scan_id`	The internal ID used in DuckDB to represent that scanner	`UBIGINT`
`file_id`	A scanner might happen over multiple files, so the file_id represents a unique file in a scanner	`UBIGINT`
`file_path`	The file path	`VARCHAR`
`delimiter`	The delimiter used e.g., ;	`VARCHAR`
`quote`	The quote used e.g., ”	`VARCHAR`
`escape`	The escape used e.g., ”	`VARCHAR`
`newline_delimiter`	The newline delimiter used e.g., \r\n	`VARCHAR`
`skip_rows`	If any rows were skipped from the top of the file	`UINTEGER`
`has_header`	If the file has a header	`BOOLEAN`
`columns`	The schema of the file (i.e., all column names and types)	`VARCHAR`
`date_format`	The format used for date types	`VARCHAR`
`timestamp_format`	The format used for timestamp types	`VARCHAR`
`user_arguments`	Any extra scanner parameters manually set by the user	`VARCHAR`

Reject Errors

The CSV Reject Errors Table returns the following information:

Column name	Description	Type
`scan_id`	The internal ID used in DuckDB to represent that scanner, used to join with reject scans tables	`UBIGINT`
`file_id`	The file_id represents a unique file in a scanner, used to join with reject scans tables	`UBIGINT`
`line`	Line number, from the CSV File, where the error occurred.	`UBIGINT`
`line_byte_position`	Byte Position of the start of the line, where the error occurred.	`UBIGINT`
`byte_position`	Byte Position where the error occurred.	`UBIGINT`
`column_idx`	If the error happens in a specific column, the index of the column.	`UBIGINT`
`column_name`	If the error happens in a specific column, the name of the column.	`VARCHAR`
`error_type`	The type of the error that happened.	`ENUM`
`csv_line`	The original CSV line.	`VARCHAR`
`error_message`	The error message produced by DuckDB.	`VARCHAR`

Parameters

The parameters listed below are used in the `read_csv` function to configure the CSV Rejects Table.

Name	Description	Type	Default
`store_rejects`	If set to true, any errors in the file will be skipped and stored in the default rejects temporary tables.	`BOOLEAN`	False
`rejects_scan`	Name of a temporary table where the information of the scan information of faulty CSV file are stored.	`VARCHAR`	reject_scans
`rejects_table`	Name of a temporary table where the information of the faulty lines of a CSV file are stored.	`VARCHAR`	reject_errors
`rejects_limit`	Upper limit on the number of faulty records from a CSV file that will be recorded in the rejects table. 0 is used when no limit should be applied.	`BIGINT`	0

To store the information of the faulty CSV lines in a rejects table, the user must simply set the `store_rejects` option to true. For example:

```
FROM read_csv(
    'faulty.csv',
    columns = {'name': 'VARCHAR', 'age': 'INTEGER'},
    store_rejects = true
);
```

You can then query both the `reject_scans` and `reject_errors` tables, to retrieve information about the rejected tuples. For example:

```
FROM reject_scans;
```

Outputs:

scan_id	file_id	file_path	delimiter	quote	escape	newline_delimiter	skip_rows	has_header	columns	date_format	timestamp_format	user_arguments
5	0	faulty.csv	,	”	”	\n	0	false	{'name': 'VARCHAR','age': 'INTEGER'}			store_rejects=true

```
FROM reject_errors;
```

Outputs:

scan_id	file_id	line	line_byte_position	byte_position	column_idx	column_name	error_type	csv_line	error_message
5	0	2	10	23	2	age	CAST	Oogie Boogie, three	Error when converting column ”age”. Could not convert string ” three” to 'INTEGER'

CSV Import Tips

Below is a collection of tips to help when attempting to import complex CSV files. In the examples, we use the `flights.csv` file.

Override the Header Flag if the Header Is Not Correctly Detected

If a file contains only string columns the `header` auto-detection might fail. Provide the `header` option to override this behavior.

```
SELECT * FROM read_csv('flights.csv', header = true);
```

Provide Names if the File Does Not Contain a Header

If the file does not contain a header, names will be auto-generated by default. You can provide your own names with the `names` option.

```
SELECT * FROM read_csv('flights.csv', names = ['DateOfFlight', 'CarrierName']);
```

Override the Types of Specific Columns

The `types` flag can be used to override types of only certain columns by providing a struct of `name` → `type` mappings.

```
SELECT * FROM read_csv('flights.csv', types = {'FlightDate': 'DATE'});
```

Use COPY When Loading Data into a Table

The COPY statement copies data directly into a table. The CSV reader uses the schema of the table instead of auto-detecting types from the file. This speeds up the auto-detection, and prevents mistakes from being made during auto-detection.

```
COPY tbl FROM 'test.csv';
```

Use `union_by_name` When Loading Files with Different Schemas

The `union_by_name` option can be used to unify the schema of files that have different or missing columns. For files that do not have certain columns, `NULL` values are filled in.

```
SELECT * FROM read_csv('flights*.csv', union_by_name = true);
```

To load data into *an existing table* where the table has more columns than the CSV file, you can use the `INSERT INTO ... BY NAME` clause:

```
INSERT INTO tbl BY NAME
    SELECT * FROM read_csv('input.csv');
```

Sample Size

If the CSV sniffer is not detecting the correct type, try increasing the sample size. The option `sample_size = -1` forces the sniffer to read the entire file:

```
SELECT * FROM read_csv('my_csv_file.csv', sample_size = -1);
```

JSON Files

JSON Overview

DuckDB supports SQL functions that are useful for reading values from existing JSON and creating new JSON data. JSON is supported with the `json` extension which is shipped with most DuckDB distributions and is auto-loaded on first use. If you would like to install or load it manually, please consult the "Installing and Loading" page.

About JSON

JSON is an open standard file format and data interchange format that uses human-readable text to store and transmit data objects consisting of attribute–value pairs and arrays (or other serializable values). While it is not a very efficient format for tabular data, it is very commonly used, especially as a data interchange format.

JSONPath and JSON Pointer Syntax

DuckDB implements multiple interfaces for JSON extraction: JSONPath and JSON Pointer. Both of them work with the arrow operator (`->`) and the `json_extract` function call.

Note that DuckDB only supports lookups in JSONPath, i.e., extracting fields with `.<key>` or array elements with `[<index>]`. Arrays can be indexed from the back and both approaches support the wildcard `*`. DuckDB does *not* support the full JSONPath syntax because SQL is readily available for any further transformations.

> It's best to pick either the JSONPath or the JSON Pointer syntax and use it in your entire application.

Indexing

> **Warning.** Following PostgreSQL's conventions, DuckDB uses 1-based indexing for its `ARRAY` and `LIST` data types but 0-based indexing for the JSON data type.

Examples

Loading JSON

Read a JSON file from disk, auto-infer options:

```
SELECT * FROM 'todos.json';
```

Use the `read_json` function with custom options:

```
SELECT *
FROM read_json('todos.json',
               format = 'array',
               columns = {userId: 'UBIGINT',
                          id: 'UBIGINT',
                          title: 'VARCHAR',
                          completed: 'BOOLEAN'});
```

Read a JSON file from stdin, auto-infer options:

```
cat data/json/todos.json | duckdb -c "SELECT * FROM read_json('/dev/stdin')"
```

Read a JSON file into a table:

```
CREATE TABLE todos (userId UBIGINT, id UBIGINT, title VARCHAR, completed BOOLEAN);
COPY todos FROM 'todos.json' (AUTO_DETECT true);
```

Alternatively, create a table without specifying the schema manually with a `CREATE TABLE ... AS SELECT` clause:

```
CREATE TABLE todos AS
    SELECT * FROM 'todos.json';
```

Since DuckDB v1.3.0, the JSON reader returns the `filename` virtual column:

```
SELECT filename, *
FROM 'todos-*.json';
```

Writing JSON

Write the result of a query to a JSON file:

```
COPY (SELECT * FROM todos) TO 'todos.json';
```

JSON Data Type

Create a table with a column for storing JSON data and insert data into it:

```
CREATE TABLE example (j JSON);
INSERT INTO example VALUES
    ('{ "family": "anatidae", "species": [ "duck", "goose", "swan", null ] }');
```

Retrieving JSON Data

Retrieve the family key's value:

```
SELECT j.family FROM example;
```

```
"anatidae"
```

Extract the family key's value with a JSONPath expression as JSON:

```
SELECT j->'$.family' FROM example;
```

```
"anatidae"
```

Extract the family key's value with a JSONPath expression as a VARCHAR:

```
SELECT j->>'$.family' FROM example;
```

```
anatidae
```

Using Quotes for Special Characters

JSON object keys that contain the special `[` and `.` characters can be used by surrounding them with double quotes (`"`):

```
SELECT '{"d[u]._\"ck":42}'->'$."d[u]._\"ck"' AS v;
```

```
42
```

Creating JSON

JSON Creation Functions

The following functions are used to create JSON.

Function	Description
`to_json(any)`	Create JSON from a value of any type. Our `LIST` is converted to a JSON array, and our STRUCT and MAP are converted to a JSON object.
`json_quote(any)`	Alias for `to_json`.
`array_to_json(list)`	Alias for `to_json` that only accepts `LIST`.
`row_to_json(list)`	Alias for `to_json` that only accepts STRUCT.
`json_array(any, ...)`	Create a JSON array from the values in the argument lists.
`json_object(key, value, ...)`	Create a JSON object from `key`, `value` pairs in the argument list. Requires an even number of arguments.
`json_merge_patch(json, json)`	Merge two JSON documents together.

Examples:

```
SELECT to_json('duck');
```

```
"duck"
```

```
SELECT to_json([1, 2, 3]);
```

```
[1,2,3]
```

```
SELECT to_json({duck : 42});
```

```
{"duck":42}
```

```
SELECT to_json(MAP(['duck'], [42]));
```

```
{"duck":42}
```

```
SELECT json_array('duck', 42, 'goose', 123);
```

```
["duck",42,"goose",123]
```

```
SELECT json_object('duck', 42, 'goose', 123);
```

```
{"duck":42,"goose":123}
```

```
SELECT json_merge_patch('{"duck": 42}', '{"goose": 123}');
```

```
{"goose":123,"duck":42}
```

Loading JSON

The DuckDB JSON reader can automatically infer which configuration flags to use by analyzing the JSON file. This will work correctly in most situations, and should be the first option attempted. In rare situations where the JSON reader cannot figure out the correct configuration, it is possible to manually configure the JSON reader to correctly parse the JSON file.

The `read_json` Function

The `read_json` is the simplest method of loading JSON files: it automatically attempts to figure out the correct configuration of the JSON reader. It also automatically deduces types of columns. In the following example, we use the `todos.json` file,

```
SELECT *
FROM read_json('todos.json')
LIMIT 5;
```

userId	id	title	completed
1	1	delectus aut autem	false
1	2	quis ut nam facilis et officia qui	false
1	3	fugiat veniam minus	false
1	4	et porro tempora	true
1	5	laboriosam mollitia et enim quasi adipisci quia provident illum	false

We can use `read_json` to create a persistent table as well:

```
CREATE TABLE todos AS
    SELECT *
    FROM read_json('todos.json');
DESCRIBE todos;
```

column_name	column_type	null	key	default	extra
userId	UBIGINT	YES	NULL	NULL	NULL
id	UBIGINT	YES	NULL	NULL	NULL
title	VARCHAR	YES	NULL	NULL	NULL
completed	BOOLEAN	YES	NULL	NULL	NULL

If we specify types for a subset of columns, `read_json` excludes columns that we don't specify:

```
SELECT *
FROM read_json(
        'todos.json',
        columns = {userId: 'UBIGINT', completed: 'BOOLEAN'}
    )
LIMIT 5;
```

Note that only the `userId` and `completed` columns are shown:

userId	completed
1	false
1	false
1	false
1	true
1	false

Multiple files can be read at once by providing a glob or a list of files. Refer to the multiple files section for more information.

Functions for Reading JSON Objects

The following table functions are used to read JSON:

Function	Description
`read_json_objects(filename)`	Read a JSON object from `filename`, where `filename` can also be a list of files or a glob pattern.
`read_ndjson_objects(filename)`	Alias for `read_json_objects` with the parameter `format` set to `newline_delimited`.
`read_json_objects_auto(filename)`	Alias for `read_json_objects` with the parameter `format` set to `auto`.

Parameters

These functions have the following parameters:

Name	Description	Type	Default
`compression`	The compression type for the file. By default this will be detected automatically from the file extension (e.g., `t.json.gz` will use gzip, `t.json` will use none). Options are `none`, `gzip`, `zstd` and `auto_detect`.	`VARCHAR`	`auto_detect`
`filename`	Whether or not an extra `filename` column should be included in the result. Since DuckDB v1.3.0, the `filename` column is added automatically as a virtual column and this option is only kept for compatibility reasons.	`BOOL`	`false`
`format`	Can be one of `auto`, `unstructured`, `newline_delimited` and `array`.	`VARCHAR`	`array`
`hive_partitioning`	Whether or not to interpret the path as a Hive partitioned path.	`BOOL`	(auto-detected)
`ignore_errors`	Whether to ignore parse errors (only possible when `format` is `newline_delimited`).	`BOOL`	`false`
`maximum_sample_files`	The maximum number of JSON files sampled for auto-detection.	`BIGINT`	`32`
`maximum_object_size`	The maximum size of a JSON object (in bytes).	`UINTEGER`	`16777216`

The `format` parameter specifies how to read the JSON from a file. With `unstructured`, the top-level JSON is read, e.g., for `birds.json`:

```
{
  "duck": 42
}
{
  "goose": [1, 2, 3]
}
```

```
FROM read_json_objects('birds.json', format = 'unstructured');
```

will result in two objects being read:

```
┌──────────────────────────────────┐
│               json               │
│               json               │
├──────────────────────────────────┤
│ {\n    "duck": 42\n}             │
│ {\n    "goose": [1, 2, 3]\n}     │
└──────────────────────────────────┘
```

With `newline_delimited`, NDJSON is read, where each JSON is separated by a newline (`\n`), e.g., for `birds-nd.json`:

```
{"duck": 42}
{"goose": [1, 2, 3]}
```

```
FROM read_json_objects('birds-nd.json', format = 'newline_delimited');
```

will also result in two objects being read:

```
┌──────────────────────┐
│         json         │
│         json         │
├──────────────────────┤
│ {"duck": 42}         │
│ {"goose": [1, 2, 3]} │
└──────────────────────┘
```

With `array`, each array element is read, e.g., for `birds-array.json`:

```
[
    {
        "duck": 42
    },
    {
        "goose": [1, 2, 3]
    }
]
```

```
FROM read_json_objects('birds-array.json', format = 'array');
```

will again result in two objects being read:

```
┌──────────────────────────────────────┐
│                 json                 │
│                 json                 │
├──────────────────────────────────────┤
│ {\n        "duck": 42\n    }         │
│ {\n        "goose": [1, 2, 3]\n    } │
└──────────────────────────────────────┘
```

Functions for Reading JSON as a Table

DuckDB also supports reading JSON as a table, using the following functions:

Function	Description
`read_json(filename)`	Read JSON from `filename`, where `filename` can also be a list of files, or a glob pattern.
`read_json_auto(filename)`	Alias for `read_json`.
`read_ndjson(filename)`	Alias for `read_json` with parameter `format` set to `newline_delimited`.
`read_ndjson_auto(filename)`	Alias for `read_json` with parameter `format` set to `newline_delimited`.

Parameters

Besides the `maximum_object_size`, `format`, `ignore_errors` and `compression`, these functions have additional parameters:

Name	Description	Type	Default
`auto_detect`	Whether to auto-detect the names of the keys and data types of the values automatically	`BOOL`	`true`
`columns`	A struct that specifies the key names and value types contained within the JSON file (e.g., `{key1: 'INTEGER', key2: 'VARCHAR'}`). If `auto_detect` is enabled these will be inferred	`STRUCT`	`(empty)`
`dateformat`	Specifies the date format to use when parsing dates. See Date Format	`VARCHAR`	`iso`
`maximum_depth`	Maximum nesting depth to which the automatic schema detection detects types. Set to -1 to fully detect nested JSON types	`BIGINT`	`-1`
`records`	Can be one of `auto`, `true`, `false`	`VARCHAR`	`auto`
`sample_size`	Option to define number of sample objects for automatic JSON type detection. Set to -1 to scan the entire input file	`UBIGINT`	`20480`
`timestampformat`	Specifies the date format to use when parsing timestamps. See Date Format. When set to `iso` (the default), ISO 8601 timestamps with timezone offsets (e.g., `2024-01-01T12:00:00+05:00`) and fractional seconds (e.g., `2024-01-01T12:00:00.123Z`) are automatically inferred as `TIMESTAMP`.	`VARCHAR`	`iso`
`union_by_name`	Whether the schemas of multiple JSON files should be unified	`BOOL`	`false`
`map_inference_threshold`	Controls the threshold for number of columns whose schema will be auto-detected; if JSON schema auto-detection would infer a `STRUCT` type for a field that has *more* than this threshold number of subfields, it infers a `MAP` type instead. Set to `-1` to disable `MAP` inference.	`BIGINT`	`200`
`field_appearance_threshold`	The JSON reader divides the number of appearances of each JSON field by the auto-detection sample size. If the average over the fields of an object is less than this threshold, it will default to using a `MAP` type with value type of merged field types.	`DOUBLE`	`0.1`

Note that DuckDB can convert JSON arrays directly to its internal `LIST` type, and missing keys become `NULL`:

```
SELECT *
FROM read_json(
    ['birds1.json', 'birds2.json'],
    columns = {duck: 'INTEGER', goose: 'INTEGER[]', swan: 'DOUBLE'}
);
```

duck	goose	swan
42	[1, 2, 3]	NULL
43	[4, 5, 6]	3.3

DuckDB can automatically detect the types like so:

```
SELECT goose, duck FROM read_json('*.json.gz');
SELECT goose, duck FROM '*.json.gz'; -- equivalent
```

DuckDB can read (and auto-detect) a variety of formats, specified with the `format` parameter. Querying a JSON file that contains an `array`, e.g.:

```
[
  {
    "duck": 42,
    "goose": 4.2
  },
  {
    "duck": 43,
    "goose": 4.3
  }
]
```

Can be queried exactly the same as a JSON file that contains `unstructured` JSON, e.g.:

```
{
    "duck": 42,
    "goose": 4.2
}
{
    "duck": 43,
    "goose": 4.3
}
```

Both can be read as the table:

```
SELECT
FROM read_json('birds.json');
```

duck	goose
42	4.2
43	4.3

If your JSON file does not contain "records", i.e., any other type of JSON than objects, DuckDB can still read it. This is specified with the `records` parameter. The `records` parameter specifies whether the JSON contains records that should be unpacked into individual columns. DuckDB also attempts to auto-detect this. For example, take the following file, `birds-records.json`:

```
{"duck": 42, "goose": [1, 2, 3]}
{"duck": 43, "goose": [4, 5, 6]}
```

```
SELECT *
FROM read_json('birds-records.json');
```

The query results in two columns:

duck	goose
42	[1,2,3]
43	[4,5,6]

You can read the same file with `records` set to `false`, to get a single column, which is a STRUCT containing the data:

json
{'duck': 42, 'goose': [1,2,3]}
{'duck': 43, 'goose': [4,5,6]}

For additional examples reading more complex data, please see the "Shredding Deeply Nested JSON, One Vector at a Time" blog post.

Loading with the COPY Statement Using `FORMAT json`

When the `json` extension is installed, `FORMAT json` is supported for `COPY FROM`, `IMPORT DATABASE`, as well as `COPY TO` and `EXPORT DATABASE`. See the COPY statement and the IMPORT / EXPORT clauses.

By default, COPY expects newline-delimited JSON. If you prefer copying data to/from a JSON array, you can specify `ARRAY true`, e.g.,

```
COPY (SELECT * FROM range(5) r(i))
TO 'numbers.json' (ARRAY true);
```

will create the following file:

```
[
    {"i":0},
    {"i":1},
    {"i":2},
    {"i":3},
    {"i":4}
]
```

This can be read back to DuckDB as follows:

```
CREATE TABLE numbers (i BIGINT);
COPY numbers FROM 'numbers.json' (ARRAY true);
```

The format can be detected automatically like so:

```
CREATE TABLE numbers (i BIGINT);
COPY numbers FROM 'numbers.json' (AUTO_DETECT true);
```

We can also create a table from the auto-detected schema:

```
CREATE TABLE numbers AS
    FROM 'numbers.json';
```

Parameters

Name	Description	Type	Default
`auto_detect`	Whether to auto-detect the names of the keys and data types of the values automatically	`BOOL`	`false`
`columns`	A struct that specifies the key names and value types contained within the JSON file (e.g., `{key1: 'INTEGER', key2: 'VARCHAR'}`). If `auto_detect` is enabled these will be inferred	`STRUCT`	`(empty)`

Name	Description	Type	Default
`compression`	The compression type for the file. By default this will be detected automatically from the file extension (e.g., `t.json.gz` will use gzip, `t.json` will use none). Options are `uncompressed`, `gzip`, `zstd` and `auto_detect`.	`VARCHAR`	`auto_detect`
`convert_strings_to_integers`	Whether strings representing integer values should be converted to a numerical type.	`BOOL`	`false`
`dateformat`	Specifies the date format to use when parsing dates. See Date Format	`VARCHAR`	`iso`
`filename`	Whether or not an extra `filename` column should be included in the result.	`BOOL`	`false`
`format`	Can be one of `auto`, `unstructured`, `newline_delimited`, `array`	`VARCHAR`	`array`
`hive_partitioning`	Whether or not to interpret the path as a Hive partitioned path.	`BOOL`	`false`
`ignore_errors`	Whether to ignore parse errors (only possible when `format` is `newline_delimited`)	`BOOL`	`false`
`maximum_depth`	Maximum nesting depth to which the automatic schema detection detects types. Set to -1 to fully detect nested JSON types	`BIGINT`	`-1`
`maximum_object_size`	The maximum size of a JSON object (in bytes)	`UINTEGER`	`16777216`
`records`	Can be one of `auto`, `true`, `false`	`VARCHAR`	`records`
`sample_size`	Option to define number of sample objects for automatic JSON type detection. Set to -1 to scan the entire input file	`UBIGINT`	`20480`
`timestampformat`	Specifies the date format to use when parsing timestamps. See Date Format	`VARCHAR`	`iso`
`union_by_name`	Whether the schemas of multiple JSON files should be unified.	`BOOL`	`false`

Writing JSON

The contents of tables or the result of queries can be written directly to a JSON file using the COPY statement. For example:

```
CREATE TABLE cities AS
    FROM (VALUES ('Amsterdam', 1), ('London', 2)) cities(name, id);
COPY cities TO 'cities.json';
```

This will result in `cities.json` with the following content:

```
{"name":"Amsterdam","id":1}
{"name":"London","id":2}
```

See the COPY statement for more information.

JSON Type

DuckDB supports `json` via the JSON logical type. For example:

```
SELECT '[1, null, {"key": "value"}]'::JSON;
```

```
[1, null, {"key": "value"}]
```

Logically, the JSON type is similar to a VARCHAR, but with the restriction that it must be valid JSON. Physically, the data is stored as a VARCHAR.

For example, you can't parse invalid JSON:

```
SELECT 'unquoted'::JSON;
```

```
Conversion Error: Malformed JSON at byte 0 of input: unexpected character.  Input: "unquoted"
```

Instead, what you probably want here is `SELECT '"quoted"'::JSON`.

Since the data is stored physically as a VARCHAR, whitespace is significant:

```
SELECT '{ "a": 5 }'::JSON = '{"a":5}'::JSON;
```

```
false
```

Please note that whitespaces are kept in roundtrips:

```
SELECT '{  "a":5 }'::JSON::VARCHAR
```

```
{  "a":5 }
```

The order of keys in objects is significant:

```
 SELECT '{"a":1,"b":2}'::JSON = '{"b":2,"a":1}'::JSON;
```

```
false
```

Duplicate keys are allowed in JSON objects:

```
SELECT '{"a":1,"a":2}'::JSON;
```

```
{"a":1,"a":2}
```

We allow any of DuckDB's types to be cast to JSON, and JSON to be cast back to any of DuckDB's types, for example, to cast JSON to DuckDB's STRUCT type, run:

```
SELECT '{"duck": 42}'::JSON::STRUCT(duck INTEGER);
```

```
{'duck': 42}
```

And back:

```
SELECT {duck: 42}::JSON;
```

```
{"duck":42}
```

This works for our nested types as shown in the example, but also for non-nested types:

```
SELECT '2023-05-12'::DATE::JSON;
```

```
"2023-05-12"
```

The only exception to this behavior is the cast from VARCHAR to JSON, which does not alter the data, but instead parses and validates the contents of the VARCHAR as JSON.

JSON Processing Functions

JSON Extraction Functions

There are two extraction functions, which have their respective operators. The operators can only be used if the string is stored as the `JSON` logical type. These functions support the same two location notations as JSON Scalar functions.

Function	Alias	Operator	Description
`json_exists(json, path)`			Returns `true` if the supplied path exists in the `json`, and `false` otherwise.
`json_extract(json, path)`	`json_extract_path`	`->`	Extracts JSON from `json` at the given `path`. If `path` is a `LIST`, the result will be a `LIST` of `JSON`.
`json_extract_string(json, path)`	`json_extract_path_text`	`->>`	Extracts `VARCHAR` from `json` at the given `path`. If `path` is a `LIST`, the result will be a `LIST` of `VARCHAR`.
`json_value(json, path)`			Extracts JSON from `json` at the given `path`. If the `json` at the supplied path is not a scalar value, it will return `NULL`.

Note that the arrow operator `->`, which is used for JSON extracts, has a low precedence as it is also used in lambda functions. Therefore, you need to surround the `->` operator with parentheses when expressing operations such as equality comparisons (`=`). For example:

```
SELECT ((JSON '{"field": 42}')->'field') = 42;
```

> **Warning.** DuckDB's JSON data type uses 0-based indexing.

Examples:

```
CREATE TABLE example (j JSON);
INSERT INTO example VALUES
    ('{ "family": "anatidae", "species": [ "duck", "goose", "swan", null ] }');

SELECT json_extract(j, '$.family') FROM example;
```

```
"anatidae"
```

```
SELECT j->'$.family' FROM example;
```

```
"anatidae"
```

```
SELECT j->'$.species[0]' FROM example;
```

```
"duck"
```

```
SELECT j->'$.species[*]' FROM example;
```

```
["duck", "goose", "swan", null]
```

```
SELECT j->>'$.species[*]' FROM example;
```

```
[duck, goose, swan, null]
```

```
SELECT j->'$.species'->0 FROM example;
```

```
"duck"
```

```
SELECT j->'species'->['/0', '/1'] FROM example;
```

```
['"duck"', '"goose"']
```

```
SELECT json_extract_string(j, '$.family') FROM example;
```

```
anatidae
```

```
SELECT j->>'$.family' FROM example;
```

```
anatidae
```

```
SELECT j->>'$.species[0]' FROM example;
```

```
duck
```

```
SELECT j->'species'->>0 FROM example;
```

```
duck
```

```
SELECT j->'species'->>['/0', '/1'] FROM example;
```

```
[duck, goose]
```

Note that DuckDB's JSON data type uses 0-based indexing.

If multiple values need to be extracted from the same JSON, it is more efficient to extract a list of paths:

The following will cause the JSON to be parsed twice:

Resulting in a slower query that uses more memory:

```
SELECT
    json_extract(j, 'family') AS family,
    json_extract(j, 'species') AS species
FROM example;
```

family	species
”anatidae”	[”duck”,”goose”,”swan”,null]

The following produces the same result but is faster and more memory-efficient:

```
WITH extracted AS (
    SELECT json_extract(j, ['family', 'species']) AS extracted_list
    FROM example
)
SELECT
    extracted_list[1] AS family,
    extracted_list[2] AS species
FROM extracted;
```

JSON Scalar Functions

The following scalar JSON functions can be used to gain information about the stored JSON values. With the exception of `json_valid(json)`, all JSON functions produce an error when invalid JSON is supplied.

We support two kinds of notations to describe locations within JSON: JSON Pointer and JSONPath.

Function	Description
`json_array_length(json[, path])`	Return the number of elements in the JSON array `json`, or `0` if it is not a JSON array. If `path` is specified, return the number of elements in the JSON array at the given `path`. If `path` is a `LIST`, the result will be `LIST` of array lengths.
`json_contains(json_haystack, json_needle)`	Returns `true` if `json_needle` is contained in `json_haystack`. Both parameters are of JSON type, but `json_needle` can also be a numeric value or a string, however the string must be wrapped in double quotes.
`json_keys(json[, path])`	Returns the keys of `json` as a `LIST` of `VARCHAR`, if `json` is a JSON object. If `path` is specified, return the keys of the JSON object at the given `path`. If `path` is a `LIST`, the result will be `LIST` of `LIST` of `VARCHAR`.
`json_structure(json)`	Return the structure of `json`. Defaults to `JSON` if the structure is inconsistent (e.g., incompatible types in an array).
`json_type(json[, path])`	Return the type of the supplied `json`, which is one of `ARRAY`, `BIGINT`, `BOOLEAN`, `DOUBLE`, `OBJECT`, `UBIGINT`, `VARCHAR` and `NULL`. If `path` is specified, return the type of the element at the given `path`. If `path` is a `LIST`, the result will be `LIST` of types.
`json_valid(json)`	Return whether `json` is valid JSON.
`json(json)`	Parse and minify `json`.

The JSONPointer syntax separates each field with a `/`. For example, to extract the first element of the array with key `duck`, you can do:

```
SELECT json_extract('{"duck": [1, 2, 3]}', '/duck/0');
```

```
1
```

The JSONPath syntax separates fields with a `.`, and accesses array elements with `[i]`, and always starts with `$`. Using the same example, we can do the following:

```
SELECT json_extract('{"duck": [1, 2, 3]}', '$.duck[0]');
```

```
1
```

Note that DuckDB's JSON data type uses 0-based indexing.

JSONPath is more expressive, and can also access from the back of lists:

```
SELECT json_extract('{"duck": [1, 2, 3]}', '$.duck[#-1]');
```

```
3
```

JSONPath also allows escaping syntax tokens, using double quotes:

```
SELECT json_extract('{"duck.goose": [1, 2, 3]}', '$."duck.goose"[1]');
```

```
2
```

Examples using the anatidae biological family:

```
CREATE TABLE example (j JSON);
INSERT INTO example VALUES
    ('{ "family": "anatidae", "species": [ "duck", "goose", "swan", null ] }');
```

```
SELECT json(j) FROM example;
```

```
{"family":"anatidae","species":["duck","goose","swan",null]}
```

```
SELECT j.family FROM example;
```

```
"anatidae"
```

```
SELECT j.species[0] FROM example;
```

```
"duck"
```

```
SELECT json_valid(j) FROM example;
```

```
true
```

```
SELECT json_valid('{');
```

```
false
```

```
SELECT json_array_length('["duck", "goose", "swan", null]');
```

```
4
```

```
SELECT json_array_length(j, 'species') FROM example;
```

```
4
```

```
SELECT json_array_length(j, '/species') FROM example;
```

```
4
```

```
SELECT json_array_length(j, '$.species') FROM example;
```

```
4
```

```
SELECT json_array_length(j, ['$.species']) FROM example;
```

```
[4]
```

```
SELECT json_type(j) FROM example;
```

```
OBJECT
```

```
SELECT json_keys(j) FROM example;
```

```
[family, species]
```

```
SELECT json_structure(j) FROM example;
```

```
{"family":"VARCHAR","species":["VARCHAR"]}
```

```
SELECT json_structure('["duck", {"family": "anatidae"}]');
```

```
["JSON"]
```

```
SELECT json_contains('{"key": "value"}', '"value"');
```

```
true
```

```
SELECT json_contains('{"key": 1}', '1');
```

```
true
```

```
SELECT json_contains('{"top_key": {"key": "value"}}', '{"key": "value"}');
```

```
true
```

JSON Aggregate Functions

There are three JSON aggregate functions.

Function	Description
`json_group_array(any)`	Return a JSON array with all values of any in the aggregation.
`json_group_object(key, value)`	Return a JSON object with all `key`, `value` pairs in the aggregation.
`json_group_structure(json)`	Return the combined `json_structure` of all `json` in the aggregation.

Examples:

```
CREATE TABLE example1 (k VARCHAR, v INTEGER);
INSERT INTO example1 VALUES ('duck', 42), ('goose', 7);
```

```
SELECT json_group_array(v) FROM example1;
```

```
[42, 7]
```

```
SELECT json_group_object(k, v) FROM example1;
```

```
{"duck":42,"goose":7}
```

```
CREATE TABLE example2 (j JSON);
INSERT INTO example2 VALUES
    ('{"family": "anatidae", "species": ["duck", "goose"], "coolness": 42.42}'),
    ('{"family": "canidae", "species": ["labrador", "bulldog"], "hair": true}');
```

```
SELECT json_group_structure(j) FROM example2;
```

```
{"family":"VARCHAR","species":["VARCHAR"],"coolness":"DOUBLE","hair":"BOOLEAN"}
```

Transforming JSON to Nested Types

In many cases, it is inefficient to extract values from JSON one-by-one. Instead, we can "extract" all values at once, transforming JSON to the nested types `LIST` and `STRUCT`.

Function	Description
`json_transform(json, structure)`	Transform `json` according to the specified `structure`.
`from_json(json, structure)`	Alias for `json_transform`.
`json_transform_strict(json, structure)`	Same as `json_transform`, but throws an error when type casting fails.
`from_json_strict(json, structure)`	Alias for `json_transform_strict`.

The `structure` argument is JSON of the same form as returned by `json_structure`. The `structure` argument can be modified to transform the JSON into the desired structure and types. It is possible to extract fewer key/value pairs than are present in the JSON, and it is also possible to extract more: missing keys become `NULL`.

Examples:

```
CREATE TABLE example (j JSON);
INSERT INTO example VALUES
    ('{"family": "anatidae", "species": ["duck", "goose"], "coolness": 42.42}'),
    ('{"family": "canidae", "species": ["labrador", "bulldog"], "hair": true}');
```

```
SELECT json_transform(j, '{"family": "VARCHAR", "coolness": "DOUBLE"}') FROM example;
```

```
{'family': anatidae, 'coolness': 42.420000}
{'family': canidae, 'coolness': NULL}
```

```
SELECT json_transform(j, '{"family": "TINYINT", "coolness": "DECIMAL(4, 2)"}') FROM example;
```

```
{'family': NULL, 'coolness': 42.42}
{'family': NULL, 'coolness': NULL}
```

```
SELECT json_transform_strict(j, '{"family": "TINYINT", "coolness": "DOUBLE"}') FROM example;
```

```
Invalid Input Error:
Failed to cast value: "anatidae"
```

JSON Table Functions

DuckDB implements two JSON table functions that take a JSON value and produce a table from it.

Function	Description
`json_each(json[,path]`	Traverse `json` and return one row for each element in the top-level array or object.
`json_tree(json[,path]`	Traverse `json` in depth-first fashion and return one row for each element in the structure.

If the element is not an array or object, the element itself is returned. If the optional `path` argument is supplied, traversal starts from the element at the given path instead of the root element.

The resulting table has the following columns:

Field	Type	Description
`key`	`VARCHAR`	Key of element relative to its parent
`value`	`JSON`	Value of element
`type`	`VARCHAR`	`json_type` (function) of this element
`atom`	`JSON`	`json_value` (function) of this element
`id`	`UBIGINT`	Element identifier, numbered by parse order
`parent`	`UBIGINT`	`id` of parent element
`fullkey`	`VARCHAR`	JSON path to element
`path`	`VARCHAR`	JSON path to parent element
`json`	`JSON` (Virtual)	The `json` parameter
`root`	`TEXT` (Virtual)	The `path` parameter
`rowid`	`BIGINT` (Virtual)	The row identifier

These functions are analogous to SQLite's functions with the same name. Note that, because the `json_each` and `json_tree` functions refer to previous subqueries in the same FROM clause, they are *lateral joins*.

Examples:

```
CREATE TABLE example (j JSON);
INSERT INTO example VALUES
    ('{"family": "anatidae", "species": ["duck", "goose"], "coolness": 42.42}'),
    ('{"family": "canidae", "species": ["labrador", "bulldog"], "hair": true}');

SELECT je.*, je.rowid
FROM example AS e, json_each(e.j) AS je;
```

key	value	type	atom	id	parent	fullkey	path	rowid
family	”anatidae”	VARCHAR	”anatidae”	2	NULL	$.family	$	0
species	[”duck”,”goose”]	ARRAY	NULL	4	NULL	$.species	$	1
coolness	42.42	DOUBLE	42.42	8	NULL	$.coolness	$	2
family	”canidae”	VARCHAR	”canidae”	2	NULL	$.family	$	0
species	[”labrador”,”bulldog”]	ARRAY	NULL	4	NULL	$.species	$	1
hair	true	BOOLEAN	true	8	NULL	$.hair	$	2

```
SELECT je.*, je.rowid
FROM example AS e, json_each(e.j, '$.species') AS je;
```

key	value	type	atom	id	parent	fullkey	path	rowid
0	”duck”	VARCHAR	”duck”	5	NULL	$.species[0]	$.species	0
1	”goose”	VARCHAR	”goose”	6	NULL	$.species[1]	$.species	1
0	”labrador”	VARCHAR	”labrador”	5	NULL	$.species[0]	$.species	0
1	”bulldog”	VARCHAR	”bulldog”	6	NULL	$.species[1]	$.species	1

```
SELECT je.key, je.value, je.type, je.id, je.parent, je.fullkey, je.rowid
FROM example AS e, json_tree(e.j) AS je;
```

key	value	type	id	parent	fullkey	rowid
NULL	{”family”:”anatidae”,”species”:[”duck”,”goose”],”coolness”:42.42}	OBJECT	0	NULL	$	0
family	”anatidae”	VARCHAR	2	0	$.family	1
species	[”duck”,”goose”]	ARRAY	4	0	$.species	2
0	”duck”	VARCHAR	5	4	$.species[0]	3
1	”goose”	VARCHAR	6	4	$.species[1]	4
coolness	42.42	DOUBLE	8	0	$.coolness	5
NULL	{”family”:”canidae”,”species”:[”labrador”,”bulldog”],”hair”:true}	OBJECT	0	NULL	$	0
family	”canidae”	VARCHAR	2	0	$.family	1
species	[”labrador”,”bulldog”]	ARRAY	4	0	$.species	2
0	”labrador”	VARCHAR	5	4	$.species[0]	3
1	”bulldog”	VARCHAR	6	4	$.species[1]	4
hair	true	BOOLEAN	8	0	$.hair	5

JSON Format Settings

The JSON extension can attempt to determine the format of a JSON file when setting `format` to `auto`. Here are some example JSON files and the corresponding `format` settings that should be used.

In each of the below cases, the `format` setting was not needed, as DuckDB was able to infer it correctly, but it is included for illustrative purposes. A query of this shape would work in each case:

```
SELECT *
FROM filename.json;
```

Format: `newline_delimited`

With `format = 'newline_delimited'` newline-delimited JSON can be parsed. Each line is a JSON.

We use the example file `records.json` with the following content:

```
{"key1":"value1", "key2": "value1"}
{"key1":"value2", "key2": "value2"}
{"key1":"value3", "key2": "value3"}
```

```
SELECT *
FROM read_json('records.json', format = 'newline_delimited');
```

key1	key2
value1	value1
value2	value2
value3	value3

Format: `array`

If the JSON file contains a JSON array of objects (pretty-printed or not), `array_of_objects` may be used. To demonstrate its use, we use the example file `records-in-array.json`:

```
[
    {"key1":"value1", "key2": "value1"},
    {"key1":"value2", "key2": "value2"},
    {"key1":"value3", "key2": "value3"}
]
```

```
SELECT *
FROM read_json('records-in-array.json', format = 'array');
```

key1	key2
value1	value1
value2	value2
value3	value3

Format: `unstructured`

If the JSON file contains JSON that is not newline-delimited or an array, `unstructured` may be used. To demonstrate its use, we use the example file `unstructured.json`:

```
{
    "key1":"value1",
    "key2":"value1"
}
{
    "key1":"value2",
    "key2":"value2"
}
{
    "key1":"value3",
    "key2":"value3"
}
```

```
SELECT *
FROM read_json('unstructured.json', format = 'unstructured');
```

key1	key2
value1	value1
value2	value2
value3	value3

`records` Options

The JSON extension can attempt to determine whether a JSON file contains records when setting `records = auto`. When `records = true`, the JSON extension expects JSON objects, and will unpack the fields of JSON objects into individual columns.

Continuing with the same example file, `records.json`:

```
{"key1":"value1", "key2": "value1"}
{"key1":"value2", "key2": "value2"}
{"key1":"value3", "key2": "value3"}
```

```
SELECT *
FROM read_json('records.json', records = true);
```

key1	key2
value1	value1
value2	value2
value3	value3

When `records = false`, the JSON extension will not unpack the top-level objects, and create STRUCTs instead:

```
SELECT *
FROM read_json('records.json', records = false);
```

json
{'key1': value1, 'key2': value1}
{'key1': value2, 'key2': value2}
{'key1': value3, 'key2': value3}

This is especially useful if we have non-object JSON, for example, `arrays.json`:

```
[1, 2, 3]
[4, 5, 6]
[7, 8, 9]
```

```
SELECT *
FROM read_json('arrays.json', records = false);
```

json
[1, 2, 3]
[4, 5, 6]
[7, 8, 9]

Installing and Loading the JSON Extension

The `json` extension is shipped by default in DuckDB builds, otherwise, it will be transparently autoloaded on first use. If you would like to install and load it manually, run:

```
INSTALL json;
LOAD json;
```

SQL to/from JSON

DuckDB provides functions to serialize and deserialize `SELECT` statements between SQL and JSON, as well as executing JSON serialized statements.

Function	Type	Description
`json_deserialize_sql(json)`	Scalar	Deserialize one or many `json` serialized statements back to an equivalent SQL string.
`json_execute_serialized_sql(varchar)`	Table	Execute `json` serialized statements and return the resulting rows. Only one statement at a time is supported for now.
`json_serialize_sql(varchar, skip_default := boolean, skip_empty := boolean, skip_null := boolean, format := boolean)`	Scalar	Serialize a set of semicolon-separated (`;`) select statements to an equivalent list of `json` serialized statements.
`PRAGMA json_execute_serialized_sql(varchar)`	Pragma	Pragma version of the `json_execute_serialized_sql` function.

The `json_serialize_sql(varchar)` function takes three optional parameters, `skip_empty`, `skip_null` and `format` that can be used to control the output of the serialized statements.

If you run the `json_execute_serialized_sql(varchar)` table function inside of a transaction the serialized statements will not be able to see any transaction local changes. This is because the statements are executed in a separate query context. You can use the `PRAGMA json_execute_serialized_sql(varchar)` pragma version to execute the statements in the same query context as the pragma, although with the limitation that the serialized JSON must be provided as a constant string, i.e., you cannot do `PRAGMA json_execute_serialized_sql(json_serialize_sql(...))`.

Note that these functions do not preserve syntactic sugar such as `FROM * SELECT ...`, so a statement round-tripped through `json_deserialize_sql(json_serialize_sql(...))` may not be identical to the original statement, but should always be semantically equivalent and produce the same output.

Examples

Simple example:

```
SELECT json_serialize_sql('SELECT 2');
```

```
{"error":false,"statements":[{"node":{"type":"SELECT_NODE","modifiers":[],"cte_map":{"map":[]},"select_
list":[{"class":"CONSTANT","type":"VALUE_CONSTANT","alias":"","query_
location":7,"value":{"type":{"id":"INTEGER","type_info":null},"is_null":false,"value":2}}],"from_
table":{"type":"EMPTY","alias":"","sample":null,"query_location":18446744073709551615},"where_
clause":null,"group_expressions":[],"group_sets":[],"aggregate_handling":"STANDARD_
HANDLING","having":null,"sample":null,"qualify":null},"named_param_map":[]}]}
```

Example with multiple statements and skip options:

```
SELECT json_serialize_sql('SELECT 1 + 2; SELECT a + b FROM tbl1', skip_empty := true, skip_null := true);
```

```
{"error":false,"statements":[{"node":{"type":"SELECT_NODE","select_
list":[{"class":"FUNCTION","type":"FUNCTION","query_location":9,"function_
name":"+","children":[{"class":"CONSTANT","type":"VALUE_CONSTANT","query_
location":7,"value":{"type":{"id":"INTEGER"},"is_
null":false,"value":1}},{"class":"CONSTANT","type":"VALUE_CONSTANT","query_
location":11,"value":{"type":{"id":"INTEGER"},"is_null":false,"value":2}}],"order_bys":{"type":"ORDER_
MODIFIER"},"distinct":false,"is_operator":true,"export_state":false}],"from_
table":{"type":"EMPTY","query_location":18446744073709551615},"aggregate_handling":"STANDARD_
HANDLING"}},{"node":{"type":"SELECT_NODE","select_list":[{"class":"FUNCTION","type":"FUNCTION","query_
location":23,"function_name":"+","children":[{"class":"COLUMN_REF","type":"COLUMN_REF","query_
location":21,"column_names":["a"]},{"class":"COLUMN_REF","type":"COLUMN_REF","query_
location":25,"column_names":["b"]}],"order_bys":{"type":"ORDER_MODIFIER"},"distinct":false,"is_
operator":true,"export_state":false}],"from_table":{"type":"BASE_TABLE","query_location":32,"table_
name":"tbl1"},"aggregate_handling":"STANDARD_HANDLING"}}]}
```

Skip the default values in the AST (e.g., `"distinct":false`):

```
SELECT json_serialize_sql('SELECT 1 + 2; SELECT a + b FROM tbl1', skip_default := true, skip_empty :=
true, skip_null := true);
```

```
{"error":false,"statements":[{"node":{"type":"SELECT_NODE","select_
list":[{"class":"FUNCTION","type":"FUNCTION","query_location":9,"function_
name":"+","children":[{"class":"CONSTANT","type":"VALUE_CONSTANT","query_
location":7,"value":{"type":{"id":"INTEGER"},"is_
null":false,"value":1}},{"class":"CONSTANT","type":"VALUE_CONSTANT","query_
location":11,"value":{"type":{"id":"INTEGER"},"is_null":false,"value":2}}],"order_bys":{"type":"ORDER_
MODIFIER"},"is_operator":true}],"from_table":{"type":"EMPTY"},"aggregate_handling":"STANDARD_
HANDLING"}},{"node":{"type":"SELECT_NODE","select_list":[{"class":"FUNCTION","type":"FUNCTION","query_

```

Example with a syntax error:

```
SELECT json_serialize_sql('TOTALLY NOT VALID SQL');
```

```
{"error":true,"error_type":"parser","error_message":"syntax error at or near \"TOTALLY\"","error_
subtype":"SYNTAX_ERROR","position":"0"}
```

Example with deserialize:

```
SELECT json_deserialize_sql(json_serialize_sql('SELECT 1 + 2'));
```

```
SELECT (1 + 2)
```

Example with deserialize and syntax sugar, which is lost during the transformation:

```
SELECT json_deserialize_sql(json_serialize_sql('FROM x SELECT 1 + 2'));
```

```
SELECT (1 + 2) FROM x
```

Example with execute:

```
SELECT * FROM json_execute_serialized_sql(json_serialize_sql('SELECT 1 + 2'));
```

```
3
```

Example with error:

```
SELECT * FROM json_execute_serialized_sql(json_serialize_sql('TOTALLY NOT VALID SQL'));
```

```
Parser Error:
Error parsing json: parser: syntax error at or near "TOTALLY"
```

Caveats

Equality Comparison

> **Warning.** Currently, equality comparison of JSON files can differ based on the context. In some cases, it is based on raw text comparison, while in other cases, it uses logical content comparison.

The following query returns true for all fields:

```
SELECT
    a != b, -- Space is part of physical JSON content. Despite equal logical content, values are treated as not equal.
    c != d, -- Same.
    c[0] = d[0], -- Equality because space was removed from physical content of fields:
    a = c[0], -- Indeed, field is equal to empty list without space...
    b != c[0], -- ... but different from empty list with space.
FROM (
    SELECT
        '[]'::JSON AS a,
        '[ ]'::JSON AS b,
        '[[]]'::JSON AS c,
        '[[ ]]'::JSON AS d
    );
```

(a != b)	(c != d)	(c[0] = d[0])	(a = c[0])	(b != c[0])
true	true	true	true	true

Multiple Files

Reading Multiple Files

DuckDB can read multiple files of different types (CSV, Parquet, JSON files) at the same time using either the glob syntax, or by providing a list of files to read. See the combining schemas page for tips on reading files with different schemas.

CSV

Read all files with a name ending in `.csv` in the folder `dir`:

```
SELECT *
FROM 'dir/*.csv';
```

Read all files with a name ending in `.csv`, two directories deep:

```
SELECT *
FROM '*/*/*.csv';
```

Read all files with a name ending in `.csv`, at any depth in the folder `dir`:

```
SELECT *
FROM 'dir/**/*.csv';
```

Read the CSV files `flights1.csv` and `flights2.csv`:

```
SELECT *
FROM read_csv(['flights1.csv', 'flights2.csv']);
```

Read the CSV files `flights1.csv` and `flights2.csv`, unifying schemas by name and outputting a `filename` column:

```
SELECT *
FROM read_csv(['flights1.csv', 'flights2.csv'], union_by_name = true, filename = true);
```

Parquet

Read all files that match the glob pattern:

```
SELECT *
FROM 'test/*.parquet';
```

Read three Parquet files and treat them as a single table:

```
SELECT *
FROM read_parquet(['file1.parquet', 'file2.parquet', 'file3.parquet']);
```

Read all Parquet files from two specific folders:

```
SELECT *
FROM read_parquet(['folder1/*.parquet', 'folder2/*.parquet']);
```

Read all Parquet files that match the glob pattern at any depth:

```
SELECT *
FROM read_parquet('dir/**/*.parquet');
```

Multi-File Reads and Globs

DuckDB can also read a series of Parquet files and treat them as if they were a single table. Note that this only works if the Parquet files have the same schema. You can specify which Parquet files you want to read using a list parameter, glob pattern matching syntax, or a combination of both.

List Parameter

The `read_parquet` function can accept a list of filenames as the input parameter.

Read three Parquet files and treat them as a single table:

```
SELECT *
FROM read_parquet(['file1.parquet', 'file2.parquet', 'file3.parquet']);
```

Glob Syntax

Any file name input to the `read_parquet` function can either be an exact filename, or use a glob syntax to read multiple files that match a pattern.

Wildcard	Description
`*`	Matches any number of any characters (including none)
`**`	Matches any number of subdirectories (including none)
`?`	Matches any single character
`[abc]`	Matches one character given in the bracket
`[a-z]`	Matches one character from the range given in the bracket

Note that the `?` wildcard in globs is not supported for reads over S3 due to HTTP encoding issues.

Here is an example that reads all the files that end with `.parquet` located in the `test` folder:

Read all files that match the glob pattern:

```
SELECT *
FROM read_parquet('test/*.parquet');
```

List of Globs

The glob syntax and the list input parameter can be combined to scan files that meet one of multiple patterns.

Read all Parquet files from 2 specific folders.

```
SELECT *
FROM read_parquet(['folder1/*.parquet', 'folder2/*.parquet']);
```

DuckDB can read multiple CSV files at the same time using either the glob syntax, or by providing a list of files to read.

Filename

The `filename` argument can be used to add an extra `filename` column to the result that indicates which row came from which file. For example:

```
SELECT *
FROM read_csv(['flights1.csv', 'flights2.csv'], union_by_name = true, filename = true);
```

FlightDate	OriginCityName	DestCityName	UniqueCarrier	filename
1988-01-01	New York, NY	Los Angeles, CA	NULL	flights1.csv
1988-01-02	New York, NY	Los Angeles, CA	NULL	flights1.csv
1988-01-03	New York, NY	Los Angeles, CA	AA	flights2.csv

> The `filename` argument also accepts a string (e.g., `filename = 'input_file'`). When provided, the string is used as the name of the added column. This is useful when the source data already contains a `filename` column and you want to avoid a name collision.

Glob Function to Find Filenames

The glob pattern matching syntax can also be used to search for filenames using the `glob` table function. It accepts one parameter: the path to search (which may include glob patterns).

Search the current directory for all files.

```
SELECT *
FROM glob('*');
```

file
test.csv
test.json
test.parquet
test2.csv
test2.parquet
todos.json

Combining Schemas

Examples

Read a set of CSV files combining columns by position:

```
SELECT * FROM read_csv('flights*.csv');
```

Read a set of CSV files combining columns by name:

```
SELECT * FROM read_csv('flights*.csv', union_by_name = true);
```

Combining Schemas

When reading from multiple files, we have to **combine schemas** from those files. That is because each file has its own schema that can differ from the other files. DuckDB offers two ways of unifying schemas of multiple files: **by column position** and **by column name**.

By default, DuckDB reads the schema of the first file provided, and then unifies columns in subsequent files by column position. This works correctly as long as all files have the same schema. If the schema of the files differs, you might want to use the `union_by_name` option to allow DuckDB to construct the schema by reading all of the names instead.

Below is an example of how both methods work.

Union by Position

By default, DuckDB unifies the columns of these different files **by position**. This means that the first column in each file is combined together, as well as the second column in each file, etc. For example, consider the following two files.

`flights1.csv`:

```
FlightDate|UniqueCarrier|OriginCityName|DestCityName
1988-01-01|AA|New York, NY|Los Angeles, CA
1988-01-02|AA|New York, NY|Los Angeles, CA
```

`flights2.csv`:

```
FlightDate|UniqueCarrier|OriginCityName|DestCityName
1988-01-03|AA|New York, NY|Los Angeles, CA
```

Reading the two files at the same time will produce the following result set:

FlightDate	UniqueCarrier	OriginCityName	DestCityName
1988-01-01	AA	New York, NY	Los Angeles, CA
1988-01-02	AA	New York, NY	Los Angeles, CA
1988-01-03	AA	New York, NY	Los Angeles, CA

This is equivalent to the SQL construct `UNION ALL`.

Union by Name

If you are processing multiple files that have different schemas, perhaps because columns have been added or renamed, it might be desirable to unify the columns of different files **by name** instead. This can be done by providing the `union_by_name` option. For example, consider the following two files, where `flights4.csv` has an extra column (`UniqueCarrier`).

`flights3.csv`:

```
FlightDate|OriginCityName|DestCityName
1988-01-01|New York, NY|Los Angeles, CA
1988-01-02|New York, NY|Los Angeles, CA
```

`flights4.csv`:

```
FlightDate|UniqueCarrier|OriginCityName|DestCityName
1988-01-03|AA|New York, NY|Los Angeles, CA
```

Reading these when unifying column names **by position** results in an error – as the two files have a different number of columns. When specifying the `union_by_name` option, the columns are correctly unified, and any missing values are set to `NULL`.

```
SELECT * FROM read_csv(['flights3.csv', 'flights4.csv'], union_by_name = true);
```

FlightDate	OriginCityName	DestCityName	UniqueCarrier
1988-01-01	New York, NY	Los Angeles, CA	NULL
1988-01-02	New York, NY	Los Angeles, CA	NULL
1988-01-03	New York, NY	Los Angeles, CA	AA

This is equivalent to the SQL construct `UNION ALL BY NAME`.

> Using the `union_by_name` option increases memory consumption.

Parquet Files

Reading and Writing Parquet Files

Examples

Read a single Parquet file:

```
SELECT * FROM 'test.parquet';
```

Figure out which columns/types are in a Parquet file:

```
DESCRIBE SELECT * FROM 'test.parquet';
```

Create a table from a Parquet file:

```
CREATE TABLE test AS
    SELECT * FROM 'test.parquet';
```

If the file does not end in `.parquet`, use the `read_parquet` function:

```
SELECT *
FROM read_parquet('test.parq');
```

Use list parameter to read three Parquet files and treat them as a single table:

```
SELECT *
FROM read_parquet(['file1.parquet', 'file2.parquet', 'file3.parquet']);
```

Read all files that match the glob pattern:

```
SELECT *
FROM 'test/*.parquet';
```

Read all files that match the glob pattern, and include the `filename` virtual column that specifies which file each row came from (this column is available by default without a configuration options since DuckDB v1.3.0):

```
SELECT *, filename
FROM read_parquet('test/*.parquet');
```

Use a list of globs to read all Parquet files from two specific folders:

```
SELECT *
FROM read_parquet(['folder1/*.parquet', 'folder2/*.parquet']);
```

Read over HTTPS:

```
SELECT *
FROM read_parquet('https://some.url/some_file.parquet');
```

Query the metadata of a Parquet file:

```
SELECT *
FROM parquet_metadata('test.parquet');
```

Query the file metadata of a Parquet file:

```sql
SELECT *
FROM parquet_file_metadata('test.parquet');
```

Query the key-value metadata of a Parquet file:

```sql
SELECT *
FROM parquet_kv_metadata('test.parquet');
```

Query the schema of a Parquet file:

```sql
SELECT *
FROM parquet_schema('test.parquet');
```

Write the results of a query to a Parquet file using the default compression (Snappy):

```sql
COPY
    (SELECT * FROM tbl)
    TO 'result-snappy.parquet'
    (FORMAT parquet);
```

Write the results from a query to a Parquet file with specific compression and row group size:

```sql
COPY
    (FROM generate_series(100_000))
    TO 'test.parquet'
    (FORMAT parquet, COMPRESSION zstd, ROW_GROUP_SIZE 100_000);
```

Export the table contents of the entire database as parquet:

```sql
EXPORT DATABASE 'target_directory' (FORMAT parquet);
```

Parquet Files

Parquet files are compressed columnar files that are efficient to load and process. DuckDB provides support for both reading and writing Parquet files in an efficient manner, as well as support for pushing filters and projections into the Parquet file scans.

> Parquet datasets differ based on the number of files, the size of individual files, the compression algorithm used, row group size, etc. These have a significant effect on performance. Please consult the Performance Guide for details.

`read_parquet` Function

Function	Description	Example
`read_parquet(path_or_list_of_paths)`	Read Parquet file(s)	`SELECT * FROM read_parquet('test.parquet');`
`parquet_scan(path_or_list_of_paths)`	Alias for `read_parquet`	`SELECT * FROM parquet_scan('test.parquet');`

If your file ends in `.parquet`, the function syntax is optional. The system will automatically infer that you are reading a Parquet file:

```sql
SELECT * FROM 'test.parquet';
```

Multiple files can be read at once by providing a glob or a list of files. Refer to the multiple files section for more information.

Parameters

There are a number of options exposed that can be passed to the `read_parquet` function or the COPY statement.

Name	Description	Type	Default
`binary_as_string`	Parquet files generated by legacy writers do not correctly set the UTF8 flag for strings, causing string columns to be loaded as BLOB instead. Set this to true to load binary columns as strings.	BOOL	`false`
`can_have_nan`	Whether FLOAT and DOUBLE columns may contain NaN values. When set to true, the reader accounts for NaN when using a column's min/max statistics for filter pushdown, since NaN does not compare as ordered.	BOOL	`false`
`encryption_config`	Configuration for Parquet encryption.	STRUCT	-
`filename`	Whether or not an extra `filename` column should be included in the result. Since DuckDB v1.3.0, the `filename` column is added automatically as a virtual column and this option is only kept for compatibility reasons.	BOOL	`false`
`file_row_number`	Whether or not to include the `file_row_number` column.	BOOL	`false`
`hive_partitioning`	Whether or not to interpret the path as a Hive partitioned path.	BOOL	(auto-detected)
`union_by_name`	Whether the columns of multiple schemas should be unified by name, rather than by position.	BOOL	`false`
`schema`	Allows you to read a Parquet file as if it has the supplied schema. Field IDs are required.	MAP	NULL

Using the `schema` Parameter

The `schema` parameter allows you to read the Parquet file using a specific schema. This is useful for renaming, adding, deleting, reordering, or casting columns when reading Parquet files.

To use the `schema` parameter, field IDs are required. To make them available when creating the Parquet using DuckDB, use:

```
COPY (SELECT 42::INTEGER AS i) TO 'integers.parquet' (FIELD_IDS {i: 0});
```

Reading Parquet files:

```
SELECT *
FROM read_parquet('integers.parquet', schema = MAP {
                    0: {name: 'renamed_i', type: 'BIGINT', default_value: NULL},
                    1: {name: 'new_column', type: 'UTINYINT', default_value: 43}
                  });
```

renamed_i int64	new_column uint8
42	43

> The `schema` parameter cannot be combined with `union_by_name = true`.

Partial Reading

DuckDB supports projection pushdown into the Parquet file itself. That is to say, when querying a Parquet file, only the columns required for the query are read. This allows you to read only the part of the Parquet file that you are interested in. This will be done automatically by DuckDB.

DuckDB also supports filter pushdown into the Parquet reader. When you apply a filter to a column that is scanned from a Parquet file, the filter will be pushed down into the scan, and can even be used to skip parts of the file using the built-in zonemaps. Note that this will depend on whether or not your Parquet file contains zonemaps.

Filter and projection pushdown provide significant performance benefits. See our blog post "Querying Parquet with Precision Using DuckDB" for more information.

Inserts and Views

You can also insert the data into a table or create a table from the Parquet file directly. This will load the data from the Parquet file and insert it into the database:

Insert the data from the Parquet file in the table:

```
INSERT INTO people
    SELECT * FROM read_parquet('test.parquet');
```

Create a table directly from a Parquet file:

```
CREATE TABLE people AS
    SELECT * FROM read_parquet('test.parquet');
```

If you wish to keep the data stored inside the Parquet file, but want to query the Parquet file directly, you can create a view over the `read_parquet` function. You can then query the Parquet file as if it were a built-in table:

Create a view over the Parquet file:

```
CREATE VIEW people AS
    SELECT * FROM read_parquet('test.parquet');
```

Query the Parquet file:

```
SELECT * FROM people;
```

Writing to Parquet Files

DuckDB also has support for writing to Parquet files using the COPY statement syntax. See the COPY Statement page for details, including all possible parameters for the COPY statement.

Write a query to a Snappy-compressed Parquet file:

```
COPY
    (SELECT * FROM tbl)
    TO 'result-snappy.parquet'
    (FORMAT parquet);
```

Write `tbl` to a zstd-compressed Parquet file:

```
COPY tbl
    TO 'result-zstd.parquet'
    (FORMAT parquet, COMPRESSION zstd);
```

Write `tbl` to a zstd-compressed Parquet file with the lowest compression level yielding the fastest compression:

```
COPY tbl
    TO 'result-zstd.parquet'
    (FORMAT parquet, COMPRESSION zstd, COMPRESSION_LEVEL 1);
```

Write to Parquet file with key-value metadata:

```
COPY (
    SELECT
        42 AS number,
        true AS is_even
) TO 'kv_metadata.parquet' (
    FORMAT parquet,
    KV_METADATA {
        number: 'Answer to life, universe, and everything',
        is_even: 'not ''odd''' -- single quotes in values must be escaped
    }
);
```

Write to a Parquet v2 file:

```
COPY tbl
    TO 'result-v2.parquet'
    (FORMAT parquet, PARQUET_VERSION 'V2');
```

Write a CSV file to an uncompressed Parquet file:

```
COPY
    'test.csv'
    TO 'result-uncompressed.parquet'
    (FORMAT parquet, COMPRESSION uncompressed);
```

Write a query to a Parquet file with zstd-compression and row group size:

```
COPY
    (FROM generate_series(100_000))
    TO 'row-groups-zstd.parquet'
    (FORMAT parquet, COMPRESSION zstd, ROW_GROUP_SIZE 100_000);
```

Write data to an LZ4-compressed Parquet file:

```
COPY
    (FROM generate_series(100_000))
    TO 'result-lz4.parquet'
    (FORMAT parquet, COMPRESSION lz4);
```

Or, equivalently:

```
COPY
    (FROM generate_series(100_000))
    TO 'result-lz4.parquet'
    (FORMAT parquet, COMPRESSION lz4_raw);
```

Write data to a Brotli-compressed Parquet file:

```
COPY
    (FROM generate_series(100_000))
    TO 'result-brotli.parquet'
    (FORMAT parquet, COMPRESSION brotli);
```

To configure the page size of Parquet file's dictionary pages, use the `STRING_DICTIONARY_PAGE_SIZE_LIMIT` option (default: 1 MB):

```
COPY
    lineitem
    TO 'lineitem-with-custom-dictionary-size.parquet'
    (FORMAT parquet, STRING_DICTIONARY_PAGE_SIZE_LIMIT 100_000);
```

DuckDB's EXPORT command can be used to export an entire database to a series of Parquet files. See the "EXPORT statement" page for more details:

Export the table contents of the entire database as Parquet:

```
EXPORT DATABASE 'target_directory' (FORMAT parquet);
```

Encryption

DuckDB supports reading and writing encrypted Parquet files.

Supported Features

The list of supported Parquet features is available in the Parquet documentation's "Implementation status" page.

Installing and Loading the Parquet Extension

The support for Parquet files is enabled via extension. The `parquet` extension is bundled with almost all clients. However, if your client does not bundle the `parquet` extension, the extension must be installed separately:

```
INSTALL parquet;
```

Querying Parquet Metadata

Parquet Metadata

The `parquet_metadata` function can be used to query the metadata contained within a Parquet file, which reveals various internal details of the Parquet file such as the statistics of the different columns. This can be useful for figuring out what kind of skipping is possible in Parquet files, or even to obtain a quick overview of what the different columns contain. The function supports glob patterns to query metadata across multiple files in parallel:

```
SELECT *
FROM parquet_metadata('test.parquet');
```

```
SELECT *
FROM parquet_metadata('data/*.parquet');
```

Below is a table of the columns returned by `parquet_metadata`.

Field	Type
file_name	VARCHAR
row_group_id	BIGINT
row_group_num_rows	BIGINT
row_group_num_columns	BIGINT
row_group_bytes	BIGINT
column_id	BIGINT

Field	Type
file_offset	BIGINT
num_values	BIGINT
path_in_schema	VARCHAR
type	VARCHAR
stats_min	VARCHAR
stats_max	VARCHAR
stats_null_count	BIGINT
stats_distinct_count	BIGINT
stats_min_value	VARCHAR
stats_max_value	VARCHAR
compression	VARCHAR
encodings	VARCHAR
index_page_offset	BIGINT
dictionary_page_offset	BIGINT
data_page_offset	BIGINT
total_compressed_size	BIGINT
total_uncompressed_size	BIGINT
key_value_metadata	MAP(BLOB, BLOB)
bloom_filter_offset	BIGINT
bloom_filter_length	BIGINT
min_is_exact	BOOLEAN
max_is_exact	BOOLEAN
row_group_compressed_bytes	BIGINT

Parquet Schema

The `parquet_schema` function can be used to query the internal schema contained within a Parquet file. Note that this is the schema as it is contained within the metadata of the Parquet file. If you want to figure out the column names and types contained within a Parquet file it is easier to use `DESCRIBE`.

Fetch the column names and column types:

```
DESCRIBE SELECT * FROM 'test.parquet';
```

Fetch the internal schema of a Parquet file:

```
SELECT *
FROM parquet_schema('test.parquet');
```

Below is a table of the columns returned by `parquet_schema`.

Field	Type
file_name	VARCHAR
name	VARCHAR

Field	Type
type	VARCHAR
type_length	VARCHAR
repetition_type	VARCHAR
num_children	BIGINT
converted_type	VARCHAR
scale	BIGINT
precision	BIGINT
field_id	BIGINT
logical_type	VARCHAR

Parquet File Metadata

The `parquet_file_metadata` function can be used to query file-level metadata such as the format version and the encryption algorithm used:

```
SELECT *
FROM parquet_file_metadata('test.parquet');
```

Below is a table of the columns returned by `parquet_file_metadata`.

Field	Type
file_name	VARCHAR
created_by	VARCHAR
num_rows	BIGINT
num_row_groups	BIGINT
format_version	BIGINT
encryption_algorithm	VARCHAR
footer_signing_key_metadata	VARCHAR
file_size_bytes	UBIGINT
footer_size	UBIGINT
column_orders	VARCHAR[]

Parquet Key-Value Metadata

The `parquet_kv_metadata` function can be used to query custom metadata defined as key-value pairs:

```
SELECT *
FROM parquet_kv_metadata('test.parquet');
```

Below is a table of the columns returned by `parquet_kv_metadata`.

Field	Type
file_name	VARCHAR

Field	Type
key	BLOB
value	BLOB

Full Metadata

The `parquet_full_metadata` function returns all metadata for a Parquet file in a single row, combining the results of `parquet_file_metadata`, `parquet_metadata`, `parquet_schema`, and `parquet_kv_metadata` as nested struct arrays:

```
SELECT *
FROM parquet_full_metadata('test.parquet');
```

Field	Type
parquet_file_metadata	STRUCT(...)[]
parquet_metadata	STRUCT(...)[]
parquet_schema	STRUCT(...)[]
parquet_kv_metadata	STRUCT(...)[]

Each struct array contains the same columns as the corresponding standalone function.

Bloom Filters

DuckDB supports Bloom filters for pruning the row groups that need to be read to answer highly selective queries. Currently, Bloom filters are supported for the following types:

- Integer types: `TINYINT`, `UTINYINT`, `SMALLINT`, `USMALLINT`, `INTEGER`, `UINTEGER`, `BIGINT`, `UBIGINT`
- Floating point types: `FLOAT`, `DOUBLE`
- `VARCHAR`
- `BLOB`

The `parquet_bloom_probe(filename, column_name, value)` function shows which row groups can be excluded when filtering for a given value of a given column using the Bloom filter. For example:

```
FROM parquet_bloom_probe('my_file.parquet', 'my_col', 500);
```

file_name	row_group_id	bloom_filter_excludes
my_file.parquet	0	true
...	...	...
my_file.parquet	9	false

Parquet Encryption

Starting with version 0.10.0, DuckDB supports reading and writing encrypted Parquet files. DuckDB broadly follows the Parquet Modular Encryption specification with some limitations.

Reading and Writing Encrypted Files

Using the PRAGMA `add_parquet_key` function, named encryption keys of 128, 192, or 256 bits can be added to a session. These keys are stored in-memory:

```
PRAGMA add_parquet_key('key128', '0123456789112345');
PRAGMA add_parquet_key('key192', '012345678911234501234567');
PRAGMA add_parquet_key('key256', '01234567891123450123456789112345');
PRAGMA add_parquet_key('key256base64', 'MDEyMzQ1Njc4OTExMjM0NTAxMjM0NTY3ODkxMTIzNDU=');
```

Writing Encrypted Parquet Files

After specifying the key (e.g., `key256`), files can be encrypted as follows:

```
COPY tbl TO 'tbl.parquet' (ENCRYPTION_CONFIG {footer_key: 'key256'});
```

Reading Encrypted Parquet Files

An encrypted Parquet file using a specific key (e.g., `key256`), can then be read as follows:

```
COPY tbl FROM 'tbl.parquet' (ENCRYPTION_CONFIG {footer_key: 'key256'});
```

Or:

```
SELECT *
FROM read_parquet('tbl.parquet', encryption_config = {footer_key: 'key256'});
```

Interoperability

DuckDB can read uniformly encrypted Parquet files written by the Arrow C++ API (e.g., via PyArrow), as long as the same encryption key is used for both the footer and all columns.

Limitations

DuckDB's Parquet encryption currently has the following limitations.

DuckDB encrypts the footer and all columns using the `footer_key`. The Parquet specification allows encryption of individual columns with different keys, e.g.:

```
COPY tbl TO 'tbl.parquet'
    (ENCRYPTION_CONFIG {
        footer_key: 'key256',
        column_keys: {key256: ['col0', 'col1']}
    });
```

However, this is unsupported at the moment and will cause an error to be thrown (for now):

```
Not implemented Error: Parquet encryption_config column_keys not yet implemented
```

Performance Implications

Note that encryption has some performance implications. Without encryption, reading/writing the `lineitem` table from TPC-H at SF1, which is 6M rows and 15 columns, from/to a Parquet file takes 0.26 and 0.99 seconds, respectively. With encryption, this takes 0.64 and 2.21 seconds, both approximately 2.5× slower than the unencrypted version.

Parquet Tips

Below is a collection of tips to help when dealing with Parquet files.

Tips for Reading Parquet Files

Use `union_by_name` When Loading Files with Different Schemas

The `union_by_name` option can be used to unify the schema of files that have different or missing columns. For files that do not have certain columns, `NULL` values are filled in:

```
SELECT *
FROM read_parquet('flights*.parquet', union_by_name = true);
```

Tips for Writing Parquet Files

Using a glob pattern upon read or a Hive partitioning structure are good ways to transparently handle multiple files.

Enabling `PER_THREAD_OUTPUT`

If the final number of Parquet files is not important, writing one file per thread can significantly improve performance:

```
COPY
    (FROM generate_series(10_000_000))
    TO 'test.parquet'
    (FORMAT parquet, PER_THREAD_OUTPUT);
```

Selecting a `ROW_GROUP_SIZE`

The `ROW_GROUP_SIZE` parameter specifies the minimum number of rows in a Parquet row group, with a minimum value equal to DuckDB's vector size, 2,048, and a default of 122,880. A Parquet row group is a partition of rows, consisting of a column chunk for each column in the dataset.

Compression algorithms are only applied per row group, so the larger the row group size, the more opportunities to compress the data. On the other hand, larger row group sizes mean that each thread keeps more data in memory before flushing when streaming results. Another argument for smaller row group sizes is that DuckDB can read Parquet row groups in parallel even within the same file and uses predicate pushdown to only scan the row groups whose metadata ranges match the `WHERE` clause of the query. However, there is some overhead associated with reading the metadata in each group.

A good rule of thumb is to ensure that the number of row groups per file is at least as large as the number of CPU threads used to query that file. More row groups beyond the thread count would improve the speed of highly selective queries, but slow down queries that must scan the whole file like aggregations.

To write a query to a Parquet file with a different row group size, run:

```
COPY
    (FROM generate_series(100_000))
    TO 'row-groups.parquet'
    (FORMAT parquet, ROW_GROUP_SIZE 100_000);
```

The ROW_GROUPS_PER_FILE Option

The ROW_GROUPS_PER_FILE parameter creates a new Parquet file if the current one has a specified number of row groups.

```
COPY
    (FROM generate_series(100_000))
    TO 'output-directory'
    (FORMAT parquet, ROW_GROUP_SIZE 20_000, ROW_GROUPS_PER_FILE 2);
```

> If multiple threads are active, the number of row groups in a file may slightly exceed the specified number of row groups to limit the amount of locking – similarly to the behavior of FILE_SIZE_BYTES. However, if PER_THREAD_OUTPUT is set, only one thread writes to each file, and it becomes accurate again.

See the Performance Guide on "File Formats" for more tips.

Partitioning

Hive Partitioning

Examples

Read data from a Hive partitioned dataset:

```
SELECT *
FROM read_parquet('orders/*/*/*.parquet', hive_partitioning = true);
```

Write a table to a Hive partitioned dataset:

```
COPY orders
TO 'orders' (FORMAT parquet, PARTITION_BY (year, month));
```

Note that the PARTITION_BY options cannot use expressions. You can produce columns on the fly using the following syntax:

```
COPY (SELECT *, year(timestamp) AS year, month(timestamp) AS month FROM services)
TO 'test' (PARTITION_BY (year, month));
```

When reading, the partition columns are read from the directory structure and can be included or excluded depending on the `hive_partitioning` parameter.

```
FROM read_parquet('test/*/*/*.parquet', hive_partitioning = false); -- will not include year, month
columns
FROM read_parquet('test/*/*/*.parquet', hive_partitioning = true);  -- will include year, month
partition columns
```

Hive Partitioning

Hive partitioning is a partitioning strategy that is used to split a table into multiple files based on **partition keys**. The files are organized into folders. Within each folder, the **partition key** has a value that is determined by the name of the folder.

Below is an example of a Hive partitioned file hierarchy. The files are partitioned on two keys (`year` and `month`).

```
orders
├── year=2021
│   ├── month=1
│   │   ├── file1.parquet
│   │   └── file2.parquet
│   └── month=2
│       └── file3.parquet
└── year=2022
    ├── month=11
    │   ├── file4.parquet
    │   └── file5.parquet
    └── month=12
        └── file6.parquet
```

Files stored in this hierarchy can be read using the `hive_partitioning` flag.

```
SELECT *
FROM read_parquet('orders/*/*/*.parquet', hive_partitioning = true);
```

When we specify the `hive_partitioning` flag, the values of the columns will be read from the directories.

Filter Pushdown

Filters on the partition keys are automatically pushed down into the files. This way the system skips reading files that are not necessary to answer a query. For example, consider the following query on the above dataset:

```
SELECT *
FROM read_parquet('orders/*/*/*.parquet', hive_partitioning = true)
WHERE year = 2022
  AND month = 11;
```

When executing this query, only the following files will be read:

```
orders
└── year=2022
    └── month=11
        ├── file4.parquet
        └── file5.parquet
```

Auto-detection

By default the system tries to infer if the provided files are in a hive partitioned hierarchy. And if so, the `hive_partitioning` flag is enabled automatically. The auto-detection will look at the names of the folders and search for a `'key' = 'value'` pattern. This behavior can be overridden by using the `hive_partitioning` configuration option:

```
SET hive_partitioning = false;
```

Hive Types

`hive_types` is a way to specify the logical types of the hive partitions in a struct:

```
SELECT *
FROM read_parquet(
    'dir/**/*.parquet',
    hive_partitioning = true,
    hive_types = {'release': DATE, 'orders': BIGINT}
);
```

`hive_types` will be auto-detected for the following types: `DATE`, `TIMESTAMP` and `BIGINT`. To switch off the auto-detection, the flag `hive_types_autocast = 0` can be set.

Writing Partitioned Files

See the Partitioned Writes section.

Partitioned Writes

Examples

Write a table to a Hive partitioned dataset of Parquet files:

```
COPY orders TO 'orders'
(FORMAT parquet, PARTITION_BY (year, month));
```

Write a table to a Hive partitioned dataset of CSV files, allowing overwrites:

```
COPY orders TO 'orders'
(FORMAT csv, PARTITION_BY (year, month), OVERWRITE_OR_IGNORE);
```

Write a table to a Hive partitioned dataset of GZIP-compressed CSV files, setting explicit data files' extension:

```
COPY orders TO 'orders'
(FORMAT csv, PARTITION_BY (year, month), COMPRESSION gzip, FILE_EXTENSION 'csv.gz');
```

Partitioned Writes

When the PARTITION_BY clause is specified for the COPY statement, the files are written in a Hive partitioned folder hierarchy. The target is the name of the root directory (in the example above: `orders`). The files are written in-order in the file hierarchy. Currently, one file is written per thread to each directory.

```
orders
├── year=2021
│   ├── month=1
│   │   ├── data_1.parquet
│   │   └── data_2.parquet
│   └── month=2
│       └── data_1.parquet
└── year=2022
    ├── month=11
    │   ├── data_1.parquet
    │   └── data_2.parquet
    └── month=12
        └── data_1.parquet
```

The values of the partitions are automatically extracted from the data. Note that it can be very expensive to write a larger number of partitions as many files will be created. The ideal partition count depends on how large your dataset is.

To limit the maximum number of files the system can keep open before flushing to disk when writing using PARTITION_BY, use the `partitioned_write_max_open_files` configuration option (default: 100):

```
SET partitioned_write_max_open_files = 10;
```

> **Best practice.** Writing data into many small partitions is expensive. It is generally recommended to have at least `100 MB` of data per partition.

Filename Pattern

By default, files will be named `data_0.parquet` or `data_0.csv`. With the flag FILENAME_PATTERN a pattern with `{i}` or `{uuid}` can be defined to create specific filenames:

- `{i}` will be replaced by an index.
- `{uuid}` will be replaced by a 128 bits long UUID.

Write a table to a Hive partitioned dataset of .parquet files, with an index in the filename:

```
COPY orders TO 'orders'
(FORMAT parquet, PARTITION_BY (year, month), OVERWRITE_OR_IGNORE, FILENAME_PATTERN 'orders_{i}');
```

Write a table to a Hive partitioned dataset of .parquet files, with unique filenames:

```
COPY orders TO 'orders'
(FORMAT parquet, PARTITION_BY (year, month), OVERWRITE_OR_IGNORE, FILENAME_PATTERN 'file_{uuid}');
```

Overwriting

By default the partitioned write will not allow overwriting existing directories. On a local file system, the OVERWRITE and OVERWRITE_OR_IGNORE options remove the existing directories. On remote file systems, overwriting is not supported.

Appending

To append to an existing Hive partitioned directory structure, use the APPEND option:

```
COPY orders TO 'orders'
(FORMAT parquet, PARTITION_BY (year, month), APPEND);
```

Using the APPEND option results in a behavior similar to the `OVERWRITE_OR_IGNORE, FILENAME_PATTERN '{uuid}'` options, but DuckDB performs an extra check for whether the file already exists and then regenerates the UUID in the rare event that it does (to avoid clashes).

Handling Slashes in Columns

To handle slashes in column names, use Percent-Encoding implemented by the `url_encode` function.

Appender

The Appender can be used to load bulk data into a DuckDB database. It is currently available in the C, C++, Go, Java and Rust APIs. The Appender is tied to a connection, and will use the transaction context of that connection when appending. An Appender always appends to a single table in the database file.

In the C++ API, the Appender works as follows:

```
DuckDB db;
Connection con(db);
// create the table
con.Query("CREATE TABLE people (id INTEGER, name VARCHAR)");
// initialize the appender
Appender appender(con, "people");
```

The AppendRow function is the easiest way of appending data. It uses recursive templates to allow you to put all the values of a single row within one function call, as follows:

```
appender.AppendRow(1, "Mark");
```

Rows can also be individually constructed using the `BeginRow`, `EndRow` and `Append` methods. This is done internally by `AppendRow`, and hence has the same performance characteristics.

```
appender.BeginRow();
appender.Append<int32_t>(2);
appender.Append<string>("Hannes");
appender.EndRow();
```

Any values added to the Appender are cached prior to being inserted into the database system for performance reasons. That means that, while appending, the rows might not be immediately visible in the system. The cache is automatically flushed when the Appender goes out of scope or when `appender.Close()` is called. The cache can also be manually flushed using the `appender.Flush()` method. After either `Flush` or `Close` is called, all the data has been written to the database system.

Date, Time and Timestamps

While numbers and strings are rather self-explanatory, dates, times and timestamps require some explanation. They can be directly appended using the methods provided by `duckdb::Date`, `duckdb::Time` or `duckdb::Timestamp`. They can also be appended using the internal `duckdb::Value` type, however, this adds some additional overheads and should be avoided if possible.

Below is a short example:

```
con.Query("CREATE TABLE dates (d DATE, t TIME, ts TIMESTAMP)");
Appender appender(con, "dates");

// construct the values using the Date/Time/Timestamp types
// (this is the most efficient approach)
appender.AppendRow(
    Date::FromDate(1992, 1, 1),
    Time::FromTime(1, 1, 1, 0),
    Timestamp::FromDatetime(Date::FromDate(1992, 1, 1), Time::FromTime(1, 1, 1, 0))
);
// construct duckdb::Value objects
appender.AppendRow(
```

```
    Value::DATE(1992, 1, 1),
    Value::TIME(1, 1, 1, 0),
    Value::TIMESTAMP(1992, 1, 1, 1, 1, 1, 0)
);
```

Commit Frequency

By default, the appender performs commits every 204,800 rows. You can change this by explicitly using transactions and surrounding your batches of AppendRow calls by `BEGIN TRANSACTION` and `COMMIT` statements.

Handling Constraint Violations

If the Appender encounters a `PRIMARY KEY` conflict or a `UNIQUE` constraint violation, it fails and returns the following error:

```
Constraint Error:
PRIMARY KEY or UNIQUE constraint violated: duplicate key "..."
```

In this case, the entire append operation fails and no rows are inserted.

Appender Support in Other Clients

The Appender is also available in the following client APIs:

- C
- Go
- Java (JDBC)
- Julia
- Rust
- Node.js

INSERT Statements

`INSERT` statements are the standard way of loading data into a relational database. When using `INSERT` statements, the values are supplied row-by-row. While simple, there is significant overhead involved in parsing and processing individual `INSERT` statements. This makes lots of individual row-by-row insertions very inefficient for bulk insertion.

> **Best practice.** As a rule-of-thumb, avoid using lots of individual row-by-row `INSERT` statements when inserting more than a few rows (i.e., avoid using `INSERT` statements as part of a loop). When bulk inserting data, try to maximize the amount of data that is inserted per statement.

If you must use `INSERT` statements to load data in a loop, avoid executing the statements in auto-commit mode. After every commit, the database is required to sync the changes made to disk to ensure no data is lost. In auto-commit mode every single statement will be wrapped in a separate transaction, meaning `fsync` will be called for every statement. This is typically unnecessary when bulk loading and will significantly slow down your program.

> **Tip.** If you absolutely must use `INSERT` statements in a loop to load data, wrap them in calls to `BEGIN TRANSACTION` and `COMMIT`.

Syntax

An example of using `INSERT INTO` to load data in a table is as follows:

```
CREATE TABLE people (id INTEGER, name VARCHAR);
INSERT INTO people VALUES (1, 'Mark'), (2, 'Hannes');
```

For a more detailed description together with a syntax diagram, see the page on the `INSERT` statement.

Lakehouse Formats

Lakehouse formats, often referred to as open table formats, are specifications for storing data in object storage while maintaining some guarantees such as ACID transactions or keeping snapshot history. Over time, multiple lakehouse formats have emerged, each one with its own unique approach to managing its metadata (a.k.a. catalog). In this page, we will go over the support that DuckDB offers for some of these formats as well as some workarounds that you can use to still use DuckDB and get close to full interoperability with these formats.

DuckDB Lakehouse Support Matrix

DuckDB supports Iceberg, Delta, Lance and DuckLake as first-class citizens. The following matrix represents what DuckDB natively supports out of the box through core extensions.

	DuckLake	Iceberg	Delta	Lance
Extension	`ducklake`	`iceberg`	`delta`	`lance`
Read	✅	✅	✅	✅
Write	✅	✅	✅	✅
Deletes	✅	✅	❌	✅
Updates	✅	✅	❌	✅
Upserting	✅	✅	❌	✅
Create table	✅	✅	❌	✅
Create table with partitions	✅	✅	❌	❌
Attaching to a catalog	✅	✅	✅*	✅
Rename table	✅	✅	❌	❌
Rename columns	✅	✅	❌	✅
Add/drop columns	✅	✅	❌	✅
Alter column type	✅	✅	❌	✅
Compaction and maintenance	✅	❌	❌	✅
Encryption	✅	❌	❌	❌
Manage table properties	✅	✅	❌	❌
Time travel	✅	✅	✅	❌
Query table changes	✅	❌	❌	❌

* Through the `unity_catalog` extension.

DuckDB aims to build native extensions with minimal dependencies. The `iceberg` extension for example, has no dependencies on third-party Iceberg libraries, which means all data and metadata operations are implemented natively in the DuckDB extension. For the `delta`

extension, we use the `delta-kernel-rs` project, which is meant to be a lightweight platform for engines to build delta integrations that are as close to native as possible.

> **Why do native implementations matter?** Native implementations allow DuckDB to do more performance optimizations such as complex filter pushdowns (with file-level and row-group level pruning) and improve memory management.

Client APIs

Client Overview

DuckDB is an in-process database system and offers client APIs ("drivers") for several languages.

Client API	Maintainer	Support tier	Latest version
C	Core team		
Command Line Interface (CLI)	Core team		
Java (JDBC)	Core team		
Go	Core team		
Node.js (node-neo)	Jeff Raymakers		
ODBC	Core team		
Python	Core team		
R	Kirill Müller		
Rust	Core team		
WebAssembly (Wasm)	Core team		
ADBC (Arrow)	Core team		
C# (.NET)	Giorgi		
C++	Core team		

The table above lists the DuckDB clients with the primary and secondary support tiers. For a list of tertiary clients, see the "Tertiary Clients" page.

Support Tiers

There are three tiers of support for clients. Primary clients are the first to receive new features and are covered by community support. Secondary clients receive new features but are not covered by community support. Finally, there are no feature or support guarantees for tertiary clients.

> The DuckDB clients listed above are open-source and we welcome community contributions to these libraries. All primary and secondary clients are available under the MIT license. For tertiary clients, please consult the repository for the license.

Compatibility

All DuckDB clients support the same DuckDB SQL syntax and use the same on-disk database format. DuckDB extensions are also portable between clients with some exceptions (see Wasm extensions).

ADBC Client

> Installation To use the DuckDB ADBC client, download the `libduckdb` archive for your platform and follow the instructions below.
>
> The latest stable version of the DuckDB ADBC client is 1.5.4.

Arrow Database Connectivity (ADBC), similarly to ODBC and JDBC, is a C-style API that enables code portability between different database systems. This allows developers to effortlessly build applications that communicate with database systems without using code specific to that system. The main difference between ADBC and ODBC/JDBC is that ADBC uses Arrow to transfer data between the database system and the application. DuckDB has an ADBC driver, which takes advantage of the zero-copy integration between DuckDB and Arrow to efficiently transfer data.

Please refer to the ADBC documentation page for a more extensive discussion on ADBC and a detailed API explanation.

Implemented Functionality

The DuckDB-ADBC driver implements the full ADBC specification, with the exception of the `ConnectionReadPartition` and `StatementExecutePartitions` functions. Both of these functions exist to support systems that internally partition the query results, which does not apply to DuckDB. In this section, we will describe the main functions that exist in ADBC, along with the arguments they take and provide examples for each function.

Database

Set of functions that operate on a database.

Function name	Description	Arguments	Example
`DatabaseNew`	Allocate a new (but uninitialized) database.	`(AdbcDatabase *database, AdbcError *error)`	`AdbcDatabaseNew(&adbc_database, &adbc_error)`
`DatabaseSetOption`	Set a char* option.	`(AdbcDatabase *database, const char *key, const char *value, AdbcError *error)`	`AdbcDatabaseSetOption(&adbc_database, "path", "test.db", &adbc_error)`
`DatabaseInit`	Finish setting options and initialize the database.	`(AdbcDatabase *database, AdbcError *error)`	`AdbcDatabaseInit(&adbc_database, &adbc_error)`
`DatabaseRelease`	Destroy the database.	`(AdbcDatabase *database, AdbcError *error)`	`AdbcDatabaseRelease(&adbc_database, &adbc_error)`

Database Options

Option	Description
`driver`	Path to the DuckDB shared library (`libduckdb.so`, `libduckdb.dylib`, or `duckdb.dll`).
`entrypoint`	Entry point function name. Must be `duckdb_adbc_init`.
`path`	Path to a DuckDB database file. If not set, an in-memory database is created.
`uri`	Alternative to `path`. Accepts plain paths or `file:` URIs (e.g., `file:test.db`, `file:///absolute/path.db`). Takes precedence over `path` if both are set.

Connection

A set of functions that create and destroy a connection to interact with a database.

Function name	Description	Arguments	Example
`ConnectionNew`	Allocate a new (but uninitialized) connection.	`(AdbcConnection*, AdbcError*)`	`AdbcConnectionNew(&adbc_connection, &adbc_error)`
`ConnectionSetOption`	Options may be set before ConnectionInit.	`(AdbcConnection*, const char*, const char*, AdbcError*)`	`AdbcConnectionSetOption(&adbc_connection, ADBC_CONNECTION_OPTION_AUTOCOMMIT, ADBC_OPTION_VALUE_DISABLED, &adbc_error)`
`ConnectionInit`	Finish setting options and initialize the connection.	`(AdbcConnection*, AdbcDatabase*, AdbcError*)`	`AdbcConnectionInit(&adbc_connection, &adbc_database, &adbc_error)`
`ConnectionRelease`	Destroy this connection.	`(AdbcConnection*, AdbcError*)`	`AdbcConnectionRelease(&adbc_connection, &adbc_error)`

A set of functions that retrieve metadata about the database. In general, these functions will return Arrow objects, specifically an ArrowArrayStream.

Function name	Description	Arguments	Example
`ConnectionGetInfo`	Get metadata about the driver and database.	`(AdbcConnection*, const uint32_t*, size_t, ArrowArrayStream*, AdbcError*)`	`AdbcConnectionGetInfo(&adbc_connection, NULL, 0, &arrow_stream, &adbc_error)`
`ConnectionGetObjects`	Get a hierarchical view of all catalogs, database schemas, tables and columns.	`(AdbcConnection*, int, const char*, const char*, const char*, const char**, const char*, ArrowArrayStream*, AdbcError*)`	`AdbcDatabaseInit(&adbc_database, &adbc_error)`

Function name	Description	Arguments	Example
`ConnectionGetTableSchema`	Get the Arrow schema of a table.	`(AdbcConnection*, const char*, const char*, const char*, ArrowSchema*, AdbcError*)`	`AdbcDatabaseRelease(&adbc_database, &adbc_error)`
`ConnectionGetTableTypes`	Get a list of table types in the database.	`(AdbcConnection*, ArrowArrayStream*, AdbcError*)`	`AdbcDatabaseNew(&adbc_database, &adbc_error)`

The `ConnectionGetInfo` function supports the following info codes:

Info code	Constant	Description
0	`ADBC_INFO_VENDOR_NAME`	Database vendor name (`duckdb`).
1	`ADBC_INFO_VENDOR_VERSION`	Database version.
100	`ADBC_INFO_DRIVER_NAME`	Driver name.
101	`ADBC_INFO_DRIVER_VERSION`	Driver version.
102	`ADBC_INFO_DRIVER_ARROW_VERSION`	Arrow library version.
103	`ADBC_INFO_DRIVER_ADBC_VERSION`	ADBC specification version supported by the driver (as an integer, e.g., `1001000` for 1.1.0).

A set of functions with transaction semantics for the connection. By default, all connections start with auto-commit mode on, but this can be turned off via the ConnectionSetOption function.

Function name	Description	Arguments	Example
`ConnectionCommit`	Commit any pending transactions.	`(AdbcConnection*, AdbcError*)`	`AdbcConnectionCommit(&adbc_connection, &adbc_error)`
`ConnectionRollback`	Rollback any pending transactions.	`(AdbcConnection*, AdbcError*)`	`AdbcConnectionRollback(&adbc_connection, &adbc_error)`

Statement

Statements hold state related to query execution. They represent both one-off queries and prepared statements. They can be reused; however, doing so will invalidate prior result sets from that statement.

The functions used to create, destroy and set options for a statement:

Function name	Description	Arguments	Example
`StatementNew`	Create a new statement for a given connection.	`(AdbcConnection*, AdbcStatement*, AdbcError*)`	`AdbcStatementNew(&adbc_connection, &adbc_statement, &adbc_error)`
`StatementRelease`	Destroy a statement.	`(AdbcStatement*, AdbcError*)`	`AdbcStatementRelease(&adbc_statement, &adbc_error)`
`StatementSetOption`	Set a string option on a statement.	`(AdbcStatement*, const char*, const char*, AdbcError*)`	`StatementSetOption(&adbc_statement, ADBC_INGEST_OPTION_TARGET_TABLE, "TABLE_NAME", &adbc_error)`

Functions related to query execution:

Function name	Description	Arguments	Example
`StatementSetSqlQuery`	Set the SQL query to execute. The query can then be executed with StatementExecuteQuery.	`(AdbcStatement*, const char*, AdbcError*)`	`AdbcStatementSetSqlQuery(&adbc_statement, "SELECT * FROM TABLE", &adbc_error)`
`StatementSetSubstraitPlan`	Set a substrait plan to execute. The query can then be executed with StatementExecuteQuery.	`(AdbcStatement*, const uint8_t*, size_t, AdbcError*)`	`AdbcStatementSetSubstraitPlan(&adbc_statement, substrait_plan, length, &adbc_error)`
`StatementExecuteQuery`	Execute a statement and get the results.	`(AdbcStatement*, ArrowArrayStream*, int64_t*, AdbcError*)`	`AdbcStatementExecuteQuery(&adbc_statement, &arrow_stream, &rows_affected, &adbc_error)`
`StatementPrepare`	Turn this statement into a prepared statement to be executed multiple times.	`(AdbcStatement*, AdbcError*)`	`AdbcStatementPrepare(&adbc_statement, &adbc_error)`

Functions related to binding, used for bulk insertion or in prepared statements.

Function name	Description	Arguments	Example
`StatementBindStream`	Bind Arrow Stream. This can be used for bulk inserts or prepared statements.	`(AdbcStatement*, ArrowArrayStream*, AdbcError*)`	`StatementBindStream(&adbc_statement, &input_data, &adbc_error)`

Ingestion Modes When ingesting data via `StatementBindStream`, the ingestion mode can be set using `ADBC_INGEST_OPTION_MODE`:

Mode	Constant	Description
Create	`ADBC_INGEST_OPTION_MODE_CREATE`	Create a new table (error if the table already exists). This is the default.
Append	`ADBC_INGEST_OPTION_MODE_APPEND`	Append to an existing table (error if the table does not exist).
Replace	`ADBC_INGEST_OPTION_MODE_REPLACE`	Drop the existing table and create a new one.
Create or Append	`ADBC_INGEST_OPTION_MODE_CREATE_APPEND`	Create a new table if it does not exist, otherwise append to it.

`StatementExecuteQuery` returns the number of rows affected through its `rows_affected` output parameter.

Ingestion Options

Option	Description
`adbc.ingest.target_table`	The target table name for ingestion.
`adbc.ingest.target_catalog`	The target catalog (attached database) for ingestion. When set without `adbc.ingest.target_db_schema`, the schema defaults to `main`.
`adbc.ingest.target_db_schema`	The target schema for ingestion.
`adbc.ingest.temporary`	Set to `enabled` to create a temporary table. Incompatible with `target_catalog` and `target_db_schema`.

Setting Up the DuckDB ADBC Driver

Before using DuckDB as an ADBC driver, you must install the `libduckdb` shared library on your system and make it available to your application. This library contains the core DuckDB engine that the ADBC driver interfaces with.

Downloading libduckdb

Download the appropriate `libduckdb` library for your platform from the DuckDB releases page:

- **Linux**: `libduckdb-linux-amd64.zip` (contains `libduckdb.so`)
- **macOS**: `libduckdb-osx-universal.zip` (contains `libduckdb.dylib`)
- **Windows**: `libduckdb-windows-amd64.zip` (contains `duckdb.dll`)

Extract the archive to obtain the shared library file.

Installing the Library

Linux

1. Extract the `libduckdb.so` file from the downloaded archive
2. Make sure your code can use the library. You can:

    - Either copy it to a system library directory (requires root access):

      ```
      sudo cp libduckdb.so /usr/local/lib/
      sudo ldconfig
      ```

    - Or place it in a custom directory and add that directory to your `LD_LIBRARY_PATH`:

      ```
      mkdir -p ~/lib
      cp libduckdb.so ~/lib/
      export LD_LIBRARY_PATH=~/lib:$LD_LIBRARY_PATH
      ```

macOS

1. Extract the `libduckdb.dylib` file from the downloaded archive
2. Make sure your code can use the library. You can:

    - Either copy it to a system library directory:

      ```
      sudo cp libduckdb.dylib /usr/local/lib/
      ```

    - Or place it in a custom directory and add that directory to your `DYLD_LIBRARY_PATH`:

      ```
      mkdir -p ~/lib
      cp libduckdb.dylib ~/lib/
      export DYLD_LIBRARY_PATH=~/lib:$DYLD_LIBRARY_PATH
      ```

Windows

1. Extract the `duckdb.dll` file from the downloaded archive
2. Place it in one of the following locations:

    - The same directory as your application executable
    - A directory listed in your `PATH` environment variable
    - The Windows system directory (e.g., `C:\Windows\System32`)

Understanding Library Paths

The `LD_LIBRARY_PATH` (Linux) and `DYLD_LIBRARY_PATH` (macOS) are environment variables that tell the system where to look for shared libraries at runtime. When your application tries to load `libduckdb`, the system searches these paths to locate the library file.

Verifying Installation

You can verify that the library is properly installed and accessible:

Linux/macOS:

```
ldd path/to/your/application  # Linux
otool -L path/to/your/application  # macOS
```

Examples

Regardless of the programming language being used, there are two database options which will be required to utilize ADBC with DuckDB. The first one is the `driver`, which takes a path to the DuckDB library (see Setting Up the DuckDB ADBC Driver above for installation instructions). The second option is the `entrypoint`, which is an exported function from the DuckDB-ADBC driver that initializes all the ADBC functions. Once we have configured these two options, we can optionally set the `path` option, providing a path on disk to store our DuckDB database. If not set, an in-memory database is created. After configuring all the necessary options, we can proceed to initialize our database. Below is how you can do so with various different language environments.

C++

We begin our C++ example by declaring the essential variables for querying data through ADBC. These variables include Error, Database, Connection, Statement handling and an Arrow Stream to transfer data between DuckDB and the application.

```
AdbcError adbc_error;
AdbcDatabase adbc_database;
AdbcConnection adbc_connection;
AdbcStatement adbc_statement;
ArrowArrayStream arrow_stream;
```

We can then initialize our database variable. Before initializing the database, we need to set the `driver` and `entrypoint` options as mentioned above. Then we set the `path` option and initialize the database. The `driver` option should point to your installed `libduckdb` library – see Setting Up the DuckDB ADBC Driver for installation instructions.

```
AdbcDatabaseNew(&adbc_database, &adbc_error);
AdbcDatabaseSetOption(&adbc_database, "driver", "path/to/libduckdb.dylib", &adbc_error);
AdbcDatabaseSetOption(&adbc_database, "entrypoint", "duckdb_adbc_init", &adbc_error);
// By default, we start an in-memory database, but you can optionally define a path to store it on disk.
AdbcDatabaseSetOption(&adbc_database, "path", "test.db", &adbc_error);
AdbcDatabaseInit(&adbc_database, &adbc_error);
```

After initializing the database, we must create and initialize a connection to it.

```
AdbcConnectionNew(&adbc_connection, &adbc_error);
AdbcConnectionInit(&adbc_connection, &adbc_database, &adbc_error);
```

We can now initialize our statement and run queries through our connection. After the `AdbcStatementExecuteQuery` the `arrow_stream` is populated with the result.

```
AdbcStatementNew(&adbc_connection, &adbc_statement, &adbc_error);
AdbcStatementSetSqlQuery(&adbc_statement, "SELECT 42", &adbc_error);
int64_t rows_affected;
AdbcStatementExecuteQuery(&adbc_statement, &arrow_stream, &rows_affected, &adbc_error);
arrow_stream.release(arrow_stream)
```

Besides running queries, we can also ingest data via `arrow_streams`. For this we need to set an option with the table name we want to insert to, bind the stream and then execute the query.

```
StatementSetOption(&adbc_statement, ADBC_INGEST_OPTION_TARGET_TABLE, "AnswerToEverything", &adbc_error);
StatementBindStream(&adbc_statement, &arrow_stream, &adbc_error);
StatementExecuteQuery(&adbc_statement, nullptr, nullptr, &adbc_error);
```

Python

The first thing to do is to use `pip` and install the ADBC Driver manager. You will also need to install the `pyarrow` to directly access Apache Arrow formatted result sets (such as using `fetch_arrow_table`).

```
pip install adbc_driver_manager pyarrow
```

> For details on the `adbc_driver_manager` package, see the `adbc_driver_manager` package documentation.

As with C++, we need to provide initialization options consisting of the location of the libduckdb shared object and entrypoint function. Notice that the `path` argument for DuckDB is passed in through the `db_kwargs` dictionary.

```python
import adbc_driver_duckdb.dbapi

with adbc_driver_duckdb.dbapi.connect("test.db") as conn, conn.cursor() as cur:
    cur.execute("SELECT 42")
    # fetch a pyarrow table
    tbl = cur.fetch_arrow_table()
    print(tbl)
```

Alongside `fetch_arrow_table`, other methods from DBApi are also implemented on the cursor, such as `fetchone` and `fetchall`. Data can also be ingested via `arrow_streams`. We just need to set options on the statement to bind the stream of data and execute the query.

```python
import adbc_driver_duckdb.dbapi
import pyarrow

data = pyarrow.record_batch(
    [[1, 2, 3, 4], ["a", "b", "c", "d"]],
    names = ["ints", "strs"],
)

with adbc_driver_duckdb.dbapi.connect("test.db") as conn, conn.cursor() as cur:
    cur.adbc_ingest("AnswerToEverything", data)
```

Go

Make sure to install the `libduckdb` library first – see Setting Up the DuckDB ADBC Driver for detailed installation instructions.

The following example uses an in-memory DuckDB database to modify in-memory Arrow RecordBatches via SQL queries:

{% raw %}

```go
package main

import (
    "bytes"
    "context"
    "fmt"
    "io"

    "github.com/apache/arrow-adbc/go/adbc"
    "github.com/apache/arrow-adbc/go/adbc/drivermgr"
    "github.com/apache/arrow-go/v18/arrow"
    "github.com/apache/arrow-go/v18/arrow/array"
    "github.com/apache/arrow-go/v18/arrow/ipc"
    "github.com/apache/arrow-go/v18/arrow/memory"
)

func _makeSampleArrowRecord() arrow.Record {
    b := array.NewFloat64Builder(memory.DefaultAllocator)
    b.AppendValues([]float64{1, 2, 3}, nil)
    col := b.NewArray()

    defer col.Release()
    defer b.Release()
```

```
    schema := arrow.NewSchema([]arrow.Field{{Name: "column1", Type: arrow.PrimitiveTypes.Float64}}, nil)
    return array.NewRecord(schema, []arrow.Array{col}, int64(col.Len()))
}

type DuckDBSQLRunner struct {
    ctx  context.Context
    conn adbc.Connection
    db   adbc.Database
}

func NewDuckDBSQLRunner(ctx context.Context) (*DuckDBSQLRunner, error) {
    var drv drivermgr.Driver
    db, err := drv.NewDatabase(map[string]string{
        "driver":     "duckdb",
        "entrypoint": "duckdb_adbc_init",
        "path":       ":memory:",
    })
    if err != nil {
        return nil, fmt.Errorf("failed to create new in-memory DuckDB database: %w", err)
    }
    conn, err := db.Open(ctx)
    if err != nil {
        return nil, fmt.Errorf("failed to open connection to new in-memory DuckDB database: %w", err)
    }
    return &DuckDBSQLRunner{ctx: ctx, conn: conn, db: db}, nil
}

func serializeRecord(record arrow.Record) (io.Reader, error) {
    buf := new(bytes.Buffer)
    wr := ipc.NewWriter(buf, ipc.WithSchema(record.Schema()))
    if err := wr.Write(record); err != nil {
        return nil, fmt.Errorf("failed to write record: %w", err)
    }
    if err := wr.Close(); err != nil {
        return nil, fmt.Errorf("failed to close writer: %w", err)
    }
    return buf, nil
}

func (r *DuckDBSQLRunner) importRecord(sr io.Reader) error {
    rdr, err := ipc.NewReader(sr)
    if err != nil {
        return fmt.Errorf("failed to create IPC reader: %w", err)
    }
    defer rdr.Release()

    _, err = adbc.IngestStream(r.ctx, r.conn, rdr, "temp_table", adbc.OptionValueIngestModeCreate,
adbc.IngestStreamOptions{})

    return err
}

func (r *DuckDBSQLRunner) runSQL(sql string) ([]arrow.Record, error) {
    stmt, err := r.conn.NewStatement()
    if err != nil {
        return nil, fmt.Errorf("failed to create new statement: %w", err)
    }
    defer stmt.Close()
```

```
    if err := stmt.SetSqlQuery(sql); err != nil {
        return nil, fmt.Errorf("failed to set SQL query: %w", err)
    }
    out, n, err := stmt.ExecuteQuery(r.ctx)
    if err != nil {
        return nil, fmt.Errorf("failed to execute query: %w", err)
    }
    defer out.Release()

    result := make([]arrow.Record, 0, n)
    for out.Next() {
        rec := out.Record()
        rec.Retain() // .Next() will release the record, so we need to retain it
        result = append(result, rec)
    }
    if out.Err() != nil {
        return nil, out.Err()
    }
    return result, nil
}

func (r *DuckDBSQLRunner) RunSQLOnRecord(record arrow.Record, sql string) ([]arrow.Record, error) {
    serializedRecord, err := serializeRecord(record)
    if err != nil {
        return nil, fmt.Errorf("failed to serialize record: %w", err)
    }
    if err := r.importRecord(serializedRecord); err != nil {
        return nil, fmt.Errorf("failed to import record: %w", err)
    }
    result, err := r.runSQL(sql)
    if err != nil {
        return nil, fmt.Errorf("failed to run SQL: %w", err)
    }

    if _, err := r.runSQL("DROP TABLE temp_table"); err != nil {
        return nil, fmt.Errorf("failed to drop temp table after running query: %w", err)
    }
    return result, nil
}

func (r *DuckDBSQLRunner) Close() {
    r.conn.Close()
    r.db.Close()
}

func main() {
    rec := _makeSampleArrowRecord()
    fmt.Println(rec)

    runner, err := NewDuckDBSQLRunner(context.Background())
    if err != nil {
        panic(err)
    }
    defer runner.Close()

    resultRecords, err := runner.RunSQLOnRecord(rec, "SELECT column1+1 FROM temp_table")
    if err != nil {
        panic(err)
    }
```

```
    for _, resultRecord := range resultRecords {
        fmt.Println(resultRecord)
        resultRecord.Release()
    }
}
```

{% endraw %}

Running it produces the following output:

```
record:
  schema:
  fields: 1
    - column1: type=float64
  rows: 3
  col[0][column1]: [1 2 3]

record:
  schema:
  fields: 1
    - (column1 + 1): type=float64, nullable
  rows: 3
  col[0][(column1 + 1)]: [2 3 4]
```

C

Overview

> Installation To use the DuckDB C API, download the `libduckdb` archive for your platform.
>
> The latest stable version of the DuckDB C API is 1.5.4.

DuckDB implements a custom C API modeled somewhat following the SQLite C API. The API is contained in the `duckdb.h` header. Continue to Startup & Shutdown to get started, or check out the Full API overview.

We also provide a SQLite API wrapper which means that if your application is programmed against the SQLite C API, you can re-link to DuckDB and it should continue working. See the `shell_helpers.cpp` file in our source repository for more information.

Installation

The DuckDB C API can be installed as part of the `libduckdb` packages. Please see the installation page for details.

Startup & Shutdown

To use DuckDB, you must first initialize a `duckdb_database` handle using `duckdb_open()`. `duckdb_open()` takes as parameter the database file to read and write from. The special value `NULL` (`nullptr`) can be used to create an **in-memory database**. Note that for an in-memory database no data is persisted to disk (i.e., all data is lost when you exit the process).

With the `duckdb_database` handle, you can create one or many `duckdb_connection` using `duckdb_connect()`. While individual connections are thread-safe, they will be locked during querying. It is therefore recommended that each thread uses its own connection to allow for the best parallel performance.

All `duckdb_connections` have to explicitly be disconnected with `duckdb_disconnect()` and the `duckdb_database` has to be explicitly closed with `duckdb_close()` to avoid memory and file handle leaking.

Example

```
duckdb_database db;
duckdb_connection con;

if (duckdb_open(NULL, &db) == DuckDBError) {
    // handle error
}
if (duckdb_connect(db, &con) == DuckDBError) {
    // handle error
}

// run queries...

// cleanup
duckdb_disconnect(&con);
duckdb_close(&db);
```

API Reference Overview

```
            duckdb_instance_cache duckdb_create_instance_cache();
duckdb_state duckdb_get_or_create_from_cache(duckdb_instance_cache instance_cache, const char *path,
duckdb_database *out_database, duckdb_config config, char **out_error);
void duckdb_destroy_instance_cache(duckdb_instance_cache *instance_cache);
duckdb_state duckdb_open(const char *path, duckdb_database *out_database);
duckdb_state duckdb_open_ext(const char *path, duckdb_database *out_database, duckdb_config config, char
**out_error);
void duckdb_close(duckdb_database *database);
duckdb_state duckdb_connect(duckdb_database database, duckdb_connection *out_connection);
void duckdb_interrupt(duckdb_connection connection);
duckdb_query_progress_type duckdb_query_progress(duckdb_connection connection);
void duckdb_disconnect(duckdb_connection *connection);
void duckdb_connection_get_client_context(duckdb_connection connection, duckdb_client_context *out_
context);
void duckdb_connection_get_arrow_options(duckdb_connection connection, duckdb_arrow_options *out_arrow_
options);
idx_t duckdb_client_context_get_connection_id(duckdb_client_context context);
void duckdb_destroy_client_context(duckdb_client_context *context);
void duckdb_destroy_arrow_options(duckdb_arrow_options *arrow_options);
const char *duckdb_library_version();
duckdb_value duckdb_get_table_names(duckdb_connection connection, const char *query, bool qualified);
```

`duckdb_create_instance_cache` Creates a new database instance cache. The instance cache is necessary if a client/program (re)opens multiple databases to the same file within the same process. Must be destroyed with 'duckdb_destroy_instance_cache'.

Return Value The database instance cache.

Syntax

```
            duckdb_instance_cache duckdb_create_instance_cache(

);
```

`duckdb_get_or_create_from_cache` Creates a new database instance in the instance cache, or retrieves an existing database instance. Must be closed with 'duckdb_close'.

Syntax

```
            duckdb_state duckdb_get_or_create_from_cache(
  duckdb_instance_cache instance_cache,
  const char *path,
  duckdb_database *out_database,
  duckdb_config config,
  char **out_error
);
```

Parameters

- `instance_cache`: The instance cache in which to create the database, or from which to take the database.
- `path`: Path to the database file on disk. Both `nullptr` and `:memory:` open or retrieve an in-memory database.
- `out_database`: The resulting cached database.
- `config`: (Optional) configuration used to create the database.
- `out_error`: If set and the function returns `DuckDBError`, this contains the error message. Note that the error message must be freed using `duckdb_free`.

Return Value DuckDBSuccess on success or DuckDBError on failure.

duckdb_destroy_instance_cache Destroys an existing database instance cache and de-allocates its memory.

Syntax

```
            void duckdb_destroy_instance_cache(
  duckdb_instance_cache *instance_cache
);
```

Parameters

- instance_cache: The instance cache to destroy.

duckdb_open Creates a new database or opens an existing database file stored at the given path. If no path is given a new in-memory database is created instead. The database must be closed with 'duckdb_close'.

Syntax

```
            duckdb_state duckdb_open(
  const char *path,
  duckdb_database *out_database
);
```

Parameters

- path: Path to the database file on disk. Both nullptr and :memory: open an in-memory database.
- out_database: The result database object.

Return Value DuckDBSuccess on success or DuckDBError on failure.

duckdb_open_ext Extended version of duckdb_open. Creates a new database or opens an existing database file stored at the given path. The database must be closed with 'duckdb_close'.

Syntax

```
            duckdb_state duckdb_open_ext(
  const char *path,
  duckdb_database *out_database,
  duckdb_config config,
  char **out_error
);
```

Parameters

- path: Path to the database file on disk. Both nullptr and :memory: open an in-memory database.
- out_database: The result database object.
- config: (Optional) configuration used to start up the database.
- out_error: If set and the function returns DuckDBError, this contains the error message. Note that the error message must be freed using duckdb_free.

Return Value DuckDBSuccess on success or DuckDBError on failure.

`duckdb_close` Closes the specified database and de-allocates all memory allocated for that database. This should be called after you are done with any database allocated through `duckdb_open` or `duckdb_open_ext`. Note that failing to call `duckdb_close` (in case of e.g., a program crash) will not cause data corruption. Still, it is recommended to always correctly close a database object after you are done with it.

Syntax

```
            void duckdb_close(
  duckdb_database *database
);
```

Parameters

- `database`: The database object to shut down.

`duckdb_connect` Opens a connection to a database. Connections are required to query the database and store transactional state associated with the connection. The instantiated connection should be closed using 'duckdb_disconnect'.

Syntax

```
            duckdb_state duckdb_connect(
  duckdb_database database,
  duckdb_connection *out_connection
);
```

Parameters

- `database`: The database file to connect to.
- `out_connection`: The result connection object.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_interrupt` Interrupt running query

Syntax

```
            void duckdb_interrupt(
  duckdb_connection connection
);
```

Parameters

- `connection`: The connection to interrupt

`duckdb_query_progress` Get progress of the running query

Syntax

```
            duckdb_query_progress_type duckdb_query_progress(
  duckdb_connection connection
);
```

Parameters

- `connection`: The working connection

Return Value -1 if no progress or a percentage of the progress

`duckdb_disconnect` Closes the specified connection and de-allocates all memory allocated for that connection.

Syntax

```
            void duckdb_disconnect(
  duckdb_connection *connection
);
```

Parameters

- `connection`: The connection to close.

`duckdb_connection_get_client_context` Retrieves the client context of the connection.

Syntax

```
            void duckdb_connection_get_client_context(
  duckdb_connection connection,
  duckdb_client_context *out_context
);
```

Parameters

- `connection`: The connection.
- `out_context`: The client context of the connection. Must be destroyed with `duckdb_destroy_client_context`.

`duckdb_connection_get_arrow_options` Retrieves the arrow options of the connection.

Syntax

```
            void duckdb_connection_get_arrow_options(
  duckdb_connection connection,
  duckdb_arrow_options *out_arrow_options
);
```

Parameters

- `connection`: The connection.

`duckdb_client_context_get_connection_id` Returns the connection id of the client context.

Syntax

```
            idx_t duckdb_client_context_get_connection_id(
  duckdb_client_context context
);
```

Parameters

- `context`: The client context.

Return Value The connection id of the client context.

`duckdb_destroy_client_context`

Destroys the client context and deallocates its memory.

Syntax

```
            void duckdb_destroy_client_context(
  duckdb_client_context *context
);
```

Parameters

- `context`: The client context to destroy.

`duckdb_destroy_arrow_options`

Destroys the arrow options and deallocates its memory.

Syntax

```
            void duckdb_destroy_arrow_options(
  duckdb_arrow_options *arrow_options
);
```

Parameters

- `arrow_options`: The arrow options to destroy.

`duckdb_library_version`

Returns the version of the linked DuckDB, with a version postfix for dev versions

Usually used for developing C extensions that must return this for a compatibility check.

Syntax

```
            const char *duckdb_library_version(

);
```

`duckdb_get_table_names`

Get the list of (fully qualified) table names of the query.

Syntax

```
            duckdb_value duckdb_get_table_names(
  duckdb_connection connection,
  const char *query,
  bool qualified
);
```

Parameters

- `connection`: The connection for which to get the table names.
- `query`: The query for which to get the table names.
- `qualified`: Returns fully qualified table names (catalog.schema.table), if set to true, else only the (not escaped) table names.

Return Value A duckdb_value of type VARCHAR[] containing the (fully qualified) table names of the query. Must be destroyed with duckdb_destroy_value.

Configuration

Configuration options can be provided to change different settings of the database system. Note that many of these settings can be changed later on using PRAGMA statements as well. The configuration object should be created, filled with values and passed to `duckdb_open_ext`.

Example

```
duckdb_database db;
duckdb_config config;

// create the configuration object
if (duckdb_create_config(&config) == DuckDBError) {
    // handle error
}
// set some configuration options
duckdb_set_config(config, "access_mode", "READ_WRITE"); // or READ_ONLY
duckdb_set_config(config, "threads", "8");
duckdb_set_config(config, "max_memory", "8GB");
duckdb_set_config(config, "default_order", "DESC");

// open the database using the configuration
if (duckdb_open_ext(NULL, &db, config, NULL) == DuckDBError) {
    // handle error
}
// cleanup the configuration object
duckdb_destroy_config(&config);

// run queries...

// cleanup
duckdb_close(&db);
```

API Reference Overview

```
           duckdb_state duckdb_create_config(duckdb_config *out_config);
size_t duckdb_config_count();
duckdb_state duckdb_get_config_flag(size_t index, const char **out_name, const char **out_description);
duckdb_state duckdb_set_config(duckdb_config config, const char *name, const char *option);
void duckdb_destroy_config(duckdb_config *config);
```

`duckdb_create_config` Initializes an empty configuration object that can be used to provide start-up options for the DuckDB instance through `duckdb_open_ext`. The duckdb_config must be destroyed using 'duckdb_destroy_config'

This will always succeed unless there is a malloc failure.

Note that `duckdb_destroy_config` should always be called on the resulting config, even if the function returns `DuckDBError`.

Syntax

```
            duckdb_state duckdb_create_config(
  duckdb_config *out_config
);
```

Parameters

- `out_config`: The result configuration object.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_config_count` This returns the total amount of configuration options available for usage with `duckdb_get_config_flag`.

This should not be called in a loop as it internally loops over all the options.

Return Value The amount of config options available.

Syntax

```
            size_t duckdb_config_count(

);
```

`duckdb_get_config_flag` Obtains a human-readable name and description of a specific configuration option. This can be used to e.g. display configuration options. This will succeed unless `index` is out of range (i.e., `>= duckdb_config_count`).

The result name or description MUST NOT be freed.

Syntax

```
            duckdb_state duckdb_get_config_flag(
  size_t index,
  const char **out_name,
  const char **out_description
);
```

Parameters

- `index`: The index of the configuration option (between 0 and `duckdb_config_count`)
- `out_name`: A name of the configuration flag.
- `out_description`: A description of the configuration flag.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_set_config` Sets the specified option for the specified configuration. The configuration option is indicated by name. To obtain a list of config options, see `duckdb_get_config_flag`.

In the source code, configuration options are defined in `config.cpp`.

This can fail if either the name is invalid, or if the value provided for the option is invalid.

Syntax

```
           duckdb_state duckdb_set_config(
  duckdb_config config,
  const char *name,
  const char *option
);
```

Parameters

- `config`: The configuration object to set the option on.
- `name`: The name of the configuration flag to set.
- `option`: The value to set the configuration flag to.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_destroy_config` Destroys the specified configuration object and de-allocates all memory allocated for the object.

Syntax

```
           void duckdb_destroy_config(
  duckdb_config *config
);
```

Parameters

- `config`: The configuration object to destroy.

Query

The `duckdb_query` method allows SQL queries to be run in DuckDB from C. This method takes two parameters, a (null-terminated) SQL query string and a `duckdb_result` result pointer. The result pointer may be `NULL` if the application is not interested in the result set or if the query produces no result. After the result is consumed, the `duckdb_destroy_result` method should be used to clean up the result.

Elements can be extracted from the `duckdb_result` object using a variety of methods. The `duckdb_column_count` can be used to extract the number of columns. `duckdb_column_name` and `duckdb_column_type` can be used to extract the names and types of individual columns.

Example

```
duckdb_state state;
duckdb_result result;

// create a table
state = duckdb_query(con, "CREATE TABLE integers (i INTEGER, j INTEGER);", NULL);
if (state == DuckDBError) {
    // handle error
}
// insert three rows into the table
state = duckdb_query(con, "INSERT INTO integers VALUES (3, 4), (5, 6), (7, NULL);", NULL);
if (state == DuckDBError) {
    // handle error
}
```

```
// query rows again
state = duckdb_query(con, "SELECT * FROM integers", &result);
if (state == DuckDBError) {
    // handle error
}
// handle the result
// ...

// destroy the result after we are done with it
duckdb_destroy_result(&result);
```

Value Extraction

Values can be extracted using either the `duckdb_fetch_chunk` function, or using the `duckdb_value` convenience functions. The `duckdb_fetch_chunk` function directly hands you data chunks in DuckDB's native array format and can therefore be very fast. The `duckdb_value` functions perform bounds- and type-checking, and will automatically cast values to the desired type. This makes them more convenient and easier to use, at the expense of being slower.

See the Types page for more information.

> For optimal performance, use `duckdb_fetch_chunk` to extract data from the query result. The `duckdb_value` functions perform internal type-checking, bounds-checking and casting which makes them slower.

`duckdb_fetch_chunk`

Below is an end-to-end example that prints the above result to CSV format using the `duckdb_fetch_chunk` function. Note that the function is NOT generic: we do need to know exactly what the types of the result columns are.

```
duckdb_database db;
duckdb_connection con;
duckdb_open(nullptr, &db);
duckdb_connect(db, &con);

duckdb_result res;
duckdb_query(con, "CREATE TABLE integers (i INTEGER, j INTEGER);", NULL);
duckdb_query(con, "INSERT INTO integers VALUES (3, 4), (5, 6), (7, NULL);", NULL);
duckdb_query(con, "SELECT * FROM integers;", &res);

// iterate until result is exhausted
while (true) {
    duckdb_data_chunk result = duckdb_fetch_chunk(res);
    if (!result) {
        // result is exhausted
        break;
    }
    // get the number of rows from the data chunk
    idx_t row_count = duckdb_data_chunk_get_size(result);
    // get the first column
    duckdb_vector col1 = duckdb_data_chunk_get_vector(result, 0);
    int32_t *col1_data = (int32_t *) duckdb_vector_get_data(col1);
    uint64_t *col1_validity = duckdb_vector_get_validity(col1);

    // get the second column
    duckdb_vector col2 = duckdb_data_chunk_get_vector(result, 1);
    int32_t *col2_data = (int32_t *) duckdb_vector_get_data(col2);
    uint64_t *col2_validity = duckdb_vector_get_validity(col2);

    // iterate over the rows
```

```
    for (idx_t row = 0; row < row_count; row++) {
        if (duckdb_validity_row_is_valid(col1_validity, row)) {
            printf("%d", col1_data[row]);
        } else {
            printf("NULL");
        }
        printf(",");
        if (duckdb_validity_row_is_valid(col2_validity, row)) {
            printf("%d", col2_data[row]);
        } else {
            printf("NULL");
        }
        printf("\n");
    }
    duckdb_destroy_data_chunk(&result);
}
// clean-up
duckdb_destroy_result(&res);
duckdb_disconnect(&con);
duckdb_close(&db);
```

This prints the following result:

```
3,4
5,6
7,NULL
```

duckdb_value

> **Deprecated.** The duckdb_value functions are deprecated and are scheduled for removal in a future release.

Below is an example that prints the above result to CSV format using the duckdb_value_varchar function. Note that the function is generic: we do not need to know about the types of the individual result columns.

```
// print the above result to CSV format using `duckdb_value_varchar`
idx_t row_count = duckdb_row_count(&result);
idx_t column_count = duckdb_column_count(&result);
for (idx_t row = 0; row < row_count; row++) {
    for (idx_t col = 0; col < column_count; col++) {
        if (col > 0) printf(",");
        auto str_val = duckdb_value_varchar(&result, col, row);
        printf("%s", str_val);
        duckdb_free(str_val);
   }
   printf("\n");
}
```

API Reference Overview

```
            duckdb_state duckdb_query(duckdb_connection connection, const char *query, duckdb_result
*out_result);
void duckdb_destroy_result(duckdb_result *result);
const char *duckdb_column_name(duckdb_result *result, idx_t col);
duckdb_type duckdb_column_type(duckdb_result *result, idx_t col);
duckdb_statement_type duckdb_result_statement_type(duckdb_result result);
duckdb_logical_type duckdb_column_logical_type(duckdb_result *result, idx_t col);
duckdb_arrow_options duckdb_result_get_arrow_options(duckdb_result *result);
idx_t duckdb_column_count(duckdb_result *result);
```

```
idx_t duckdb_row_count(duckdb_result *result);
idx_t duckdb_rows_changed(duckdb_result *result);
void *duckdb_column_data(duckdb_result *result, idx_t col);
bool *duckdb_nullmask_data(duckdb_result *result, idx_t col);
const char *duckdb_result_error(duckdb_result *result);
duckdb_error_type duckdb_result_error_type(duckdb_result *result);
```

`duckdb_query` Executes a SQL query within a connection and stores the full (materialized) result in the out_result pointer. If the query fails to execute, DuckDBError is returned and the error message can be retrieved by calling `duckdb_result_error`.

Note that after running `duckdb_query`, `duckdb_destroy_result` must be called on the result object even if the query fails, otherwise the error stored within the result will not be freed correctly.

Syntax

```
            duckdb_state duckdb_query(
  duckdb_connection connection,
  const char *query,
  duckdb_result *out_result
);
```

Parameters

- `connection`: The connection to perform the query in.
- `query`: The SQL query to run.
- `out_result`: The query result.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_destroy_result` Closes the result and de-allocates all memory allocated for that result.

Syntax

```
            void duckdb_destroy_result(
  duckdb_result *result
);
```

Parameters

- `result`: The result to destroy.

`duckdb_column_name` Returns the column name of the specified column. The result should not need to be freed; the column names will automatically be destroyed when the result is destroyed.

Returns `NULL` if the column is out of range.

Syntax

```
            const char *duckdb_column_name(
  duckdb_result *result,
  idx_t col
);
```

Parameters

- `result`: The result object to fetch the column name from.
- `col`: The column index.

Return Value The column name of the specified column.

`duckdb_column_type` Returns the column type of the specified column.

Returns DUCKDB_TYPE_INVALID if the column is out of range.

Syntax

```
            duckdb_type duckdb_column_type(
  duckdb_result *result,
  idx_t col
);
```

Parameters

- `result`: The result object to fetch the column type from.
- `col`: The column index.

Return Value The column type of the specified column.

`duckdb_result_statement_type` Returns the statement type of the statement that was executed

Syntax

```
            duckdb_statement_type duckdb_result_statement_type(
  duckdb_result result
);
```

Parameters

- `result`: The result object to fetch the statement type from.

Return Value duckdb_statement_type value or DUCKDB_STATEMENT_TYPE_INVALID

`duckdb_column_logical_type` Returns the logical column type of the specified column.

The return type of this call should be destroyed with `duckdb_destroy_logical_type`.

Returns NULL if the column is out of range.

Syntax

```
            duckdb_logical_type duckdb_column_logical_type(
  duckdb_result *result,
  idx_t col
);
```

Parameters

- `result`: The result object to fetch the column type from.
- `col`: The column index.

Return Value The logical column type of the specified column.

`duckdb_result_get_arrow_options` Returns the arrow options associated with the given result. These options are definitions of how the arrow arrays/schema should be produced.

Syntax

```
            duckdb_arrow_options duckdb_result_get_arrow_options(
  duckdb_result *result
);
```

Parameters

- `result`: The result object to fetch arrow options from.

Return Value The arrow options associated with the given result. This must be destroyed with `duckdb_destroy_arrow_options`.

`duckdb_column_count` Returns the number of columns present in the result object.

Syntax

```
            idx_t duckdb_column_count(
  duckdb_result *result
);
```

Parameters

- `result`: The result object.

Return Value The number of columns present in the result object.

`duckdb_row_count`

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Returns the number of rows present in the result object.

Syntax

```
            idx_t duckdb_row_count(
  duckdb_result *result
);
```

Parameters

- `result`: The result object.

Return Value The number of rows present in the result object.

duckdb_rows_changed Returns the number of rows changed by the query stored in the result. This is relevant only for INSERT/UPDATE/DELETE queries. For other queries the rows_changed will be 0.

Syntax

```
            idx_t duckdb_rows_changed(
  duckdb_result *result
);
```

Parameters

- `result`: The result object.

Return Value The number of rows changed.

duckdb_column_data

> **Deprecated.** This method has been deprecated. Prefer using `duckdb_result_get_chunk` instead.

Returns the data of a specific column of a result in columnar format.

The function returns a dense array which contains the result data. The exact type stored in the array depends on the corresponding duckdb_type (as provided by `duckdb_column_type`). For the exact type by which the data should be accessed, see the comments in the types section or the DUCKDB_TYPE enum.

For example, for a column of type DUCKDB_TYPE_INTEGER, rows can be accessed in the following manner:

```
int32_t *data = (int32_t *) duckdb_column_data(&result, 0);
printf("Data for row %d: %d\n", row, data[row]);
```

Syntax

```
            void *duckdb_column_data(
  duckdb_result *result,
  idx_t col
);
```

Parameters

- `result`: The result object to fetch the column data from.
- `col`: The column index.

Return Value The column data of the specified column.

duckdb_nullmask_data

> **Deprecated.** This method has been deprecated. Prefer using `duckdb_result_get_chunk` instead.

Returns the nullmask of a specific column of a result in columnar format. The nullmask indicates for every row whether or not the corresponding row is NULL. If a row is NULL, the values present in the array provided by `duckdb_column_data` are undefined.

```
int32_t *data = (int32_t *) duckdb_column_data(&result, 0);
bool *nullmask = duckdb_nullmask_data(&result, 0);
if (nullmask[row]) {
    printf("Data for row %d: NULL\n", row);
} else {
    printf("Data for row %d: %d\n", row, data[row]);
}
```

Syntax

```
            bool *duckdb_nullmask_data(
  duckdb_result *result,
  idx_t col
);
```

Parameters

- `result`: The result object to fetch the nullmask from.
- `col`: The column index.

Return Value The nullmask of the specified column.

`duckdb_result_error` Returns the error message contained within the result. The error is only set if `duckdb_query` returns `DuckDBError`.

The result of this function must not be freed. It will be cleaned up when `duckdb_destroy_result` is called.

Syntax

```
            const char *duckdb_result_error(
  duckdb_result *result
);
```

Parameters

- `result`: The result object to fetch the error from.

Return Value The error of the result.

`duckdb_result_error_type` Returns the result error type contained within the result. The error is only set if `duckdb_query` returns `DuckDBError`.

Syntax

```
            duckdb_error_type duckdb_result_error_type(
  duckdb_result *result
);
```

Parameters

- `result`: The result object to fetch the error from.

Return Value The error type of the result.

Data Chunks

Data chunks represent a horizontal slice of a table. They hold a number of vectors, that can each hold up to the `VECTOR_SIZE` rows. The vector size can be obtained through the `duckdb_vector_size` function and is configurable, but is usually set to `2048`.

Data chunks and vectors are what DuckDB uses natively to store and represent data. For this reason, the data chunk interface is the most efficient way of interfacing with DuckDB. Be aware, however, that correctly interfacing with DuckDB using the data chunk API does require knowledge of DuckDB's internal vector format.

Data chunks can be used in two manners:

- **Reading Data**: Data chunks can be obtained from query results using the `duckdb_fetch_chunk` method, or as input to a user-defined function. In this case, the vector methods can be used to read individual values.
- **Writing Data**: Data chunks can be created using `duckdb_create_data_chunk`. The data chunk can then be filled with values and used in `duckdb_append_data_chunk` to write data to the database.

The primary manner of interfacing with data chunks is by obtaining the internal vectors of the data chunk using the `duckdb_data_chunk_get_vector` method. Afterwards, the vector methods can be used to read from or write to the individual vectors.

API Reference Overview

```
            duckdb_data_chunk duckdb_create_data_chunk(duckdb_logical_type *types, idx_t column_count);
void duckdb_destroy_data_chunk(duckdb_data_chunk *chunk);
void duckdb_data_chunk_reset(duckdb_data_chunk chunk);
idx_t duckdb_data_chunk_get_column_count(duckdb_data_chunk chunk);
duckdb_vector duckdb_data_chunk_get_vector(duckdb_data_chunk chunk, idx_t col_idx);
idx_t duckdb_data_chunk_get_size(duckdb_data_chunk chunk);
void duckdb_data_chunk_set_size(duckdb_data_chunk chunk, idx_t size);
```

`duckdb_create_data_chunk` Creates an empty data chunk with the specified column types. The result must be destroyed with `duckdb_destroy_data_chunk`.

Syntax

```
            duckdb_data_chunk duckdb_create_data_chunk(
  duckdb_logical_type *types,
  idx_t column_count
);
```

Parameters

- `types`: An array of column types. Column types cannot contain ANY and INVALID types.
- `column_count`: The number of columns.

Return Value The data chunk.

`duckdb_destroy_data_chunk` Destroys the data chunk and de-allocates all memory allocated for that chunk.

Syntax

```
            void duckdb_destroy_data_chunk(
  duckdb_data_chunk *chunk
);
```

Parameters

- chunk: The data chunk to destroy.

`duckdb_data_chunk_reset` Resets a data chunk, clearing the validity masks and setting the cardinality of the data chunk to 0. After calling this method, you must call `duckdb_vector_get_validity` and `duckdb_vector_get_data` to obtain current data and validity pointers

Syntax

```
            void duckdb_data_chunk_reset(
  duckdb_data_chunk chunk
);
```

Parameters

- chunk: The data chunk to reset.

`duckdb_data_chunk_get_column_count` Retrieves the number of columns in a data chunk.

Syntax

```
            idx_t duckdb_data_chunk_get_column_count(
  duckdb_data_chunk chunk
);
```

Parameters

- chunk: The data chunk to get the data from

Return Value The number of columns in the data chunk

`duckdb_data_chunk_get_vector` Retrieves the vector at the specified column index in the data chunk.

The pointer to the vector is valid for as long as the chunk is alive. It does NOT need to be destroyed.

Syntax

```
            duckdb_vector duckdb_data_chunk_get_vector(
  duckdb_data_chunk chunk,
  idx_t col_idx
);
```

Parameters

- chunk: The data chunk to get the data from

Return Value The vector

`duckdb_data_chunk_get_size` Retrieves the current number of tuples in a data chunk.

Syntax

```
            idx_t duckdb_data_chunk_get_size(
  duckdb_data_chunk chunk
);
```

Parameters

- chunk: The data chunk to get the data from

Return Value The number of tuples in the data chunk

`duckdb_data_chunk_set_size` Sets the current number of tuples in a data chunk.

Syntax

```
            void duckdb_data_chunk_set_size(
  duckdb_data_chunk chunk,
  idx_t size
);
```

Parameters

- chunk: The data chunk to set the size in
- size: The number of tuples in the data chunk

Vectors

Vectors represent a horizontal slice of a column. They hold a number of values of a specific type, similar to an array. Vectors are the core data representation used in DuckDB. Vectors are typically stored within data chunks.

The vector and data chunk interfaces are the most efficient way of interacting with DuckDB, allowing for the highest performance. However, the interfaces are also difficult to use and care must be taken when using them.

Vector Format

Vectors are arrays of a specific data type. The logical type of a vector can be obtained using `duckdb_vector_get_column_type`. The type id of the logical type can then be obtained using `duckdb_get_type_id`.

Vectors themselves do not have sizes. Instead, the parent data chunk has a size (that can be obtained through `duckdb_data_chunk_get_size`). All vectors that belong to a data chunk have the same size.

Primitive Types

For primitive types, the underlying array can be obtained using the `duckdb_vector_get_data` method. The array can then be accessed using the correct native type. Below is a table that contains a mapping of the `duckdb_type` to the native type of the array.

duckdb_type	NativeType
DUCKDB_TYPE_BOOLEAN	bool
DUCKDB_TYPE_TINYINT	int8_t

duckdb_type	NativeType
DUCKDB_TYPE_SMALLINT	int16_t
DUCKDB_TYPE_INTEGER	int32_t
DUCKDB_TYPE_BIGINT	int64_t
DUCKDB_TYPE_UTINYINT	uint8_t
DUCKDB_TYPE_USMALLINT	uint16_t
DUCKDB_TYPE_UINTEGER	uint32_t
DUCKDB_TYPE_UBIGINT	uint64_t
DUCKDB_TYPE_FLOAT	float
DUCKDB_TYPE_DOUBLE	double
DUCKDB_TYPE_TIMESTAMP	duckdb_timestamp
DUCKDB_TYPE_DATE	duckdb_date
DUCKDB_TYPE_TIME	duckdb_time
DUCKDB_TYPE_INTERVAL	duckdb_interval
DUCKDB_TYPE_HUGEINT	duckdb_hugeint
DUCKDB_TYPE_UHUGEINT	duckdb_uhugeint
DUCKDB_TYPE_VARCHAR	duckdb_string_t
DUCKDB_TYPE_BLOB	duckdb_string_t
DUCKDB_TYPE_TIMESTAMP_S	duckdb_timestamp
DUCKDB_TYPE_TIMESTAMP_MS	duckdb_timestamp
DUCKDB_TYPE_TIMESTAMP_NS	duckdb_timestamp
DUCKDB_TYPE_UUID	duckdb_hugeint
DUCKDB_TYPE_TIME_TZ	duckdb_time_tz
DUCKDB_TYPE_TIMESTAMP_TZ	duckdb_timestamp

NULL Values

Any value in a vector can be NULL. When a value is NULL, the values contained within the primary array at that index is undefined (and can be uninitialized). The validity mask is a bitmask consisting of `uint64_t` elements. For every 64 values in the vector, one `uint64_t` element exists (rounded up). The validity mask has its bit set to 1 if the value is valid, or set to 0 if the value is invalid (i.e., NULL).

The bits of the bitmask can be read directly, or the slower helper method `duckdb_validity_row_is_valid` can be used to check whether or not a value is NULL.

The `duckdb_vector_get_validity` returns a pointer to the validity mask. Note that if all values in a vector are valid, this function **might** return `nullptr` in which case the validity mask does not need to be checked.

Strings

String values are stored as a `duckdb_string_t`. This is a special struct that stores the string inline (if it is short, i.e., `<= 12 bytes`) or a pointer to the string data if it is longer than 12 bytes.

```
typedef struct {
    union {
        struct {
            uint32_t length;
```

```
            char prefix[4];
            char *ptr;
        } pointer;
        struct {
            uint32_t length;
            char inlined[12];
        } inlined;
    } value;
} duckdb_string_t;
```

The length can either be accessed directly, or the `duckdb_string_is_inlined` can be used to check if a string is inlined.

Decimals

Decimals are stored as integer values internally. The exact native type depends on the `width` of the decimal type, as shown in the following table:

Width	NativeType
<= 4	int16_t
<= 9	int32_t
<= 18	int64_t
<= 38	duckdb_hugeint

The `duckdb_decimal_internal_type` can be used to obtain the internal type of the decimal.

Decimals are stored as integer values multiplied by `10^scale`. The scale of a decimal can be obtained using `duckdb_decimal_scale`. For example, a decimal value of `10.5` with type `DECIMAL(8, 3)` is stored internally as an `int32_t` value of `10500`. In order to obtain the correct decimal value, the value should be divided by the appropriate power-of-ten.

Enums

Enums are stored as unsigned integer values internally. The exact native type depends on the size of the enum dictionary, as shown in the following table:

Dictionary size	NativeType
<= 255	uint8_t
<= 65535	uint16_t
<= 4294967295	uint32_t

The `duckdb_enum_internal_type` can be used to obtain the internal type of the enum.

In order to obtain the actual string value of the enum, the `duckdb_enum_dictionary_value` function must be used to obtain the enum value that corresponds to the given dictionary entry. Note that the enum dictionary is the same for the entire column – and so only needs to be constructed once.

Structs

Structs are nested types that contain any number of child types. Think of them like a `struct` in C. The way to access struct data using vectors is to access the child vectors recursively using the `duckdb_struct_vector_get_child` method.

The struct vector itself does not have any data (i.e., you should not use `duckdb_vector_get_data` method on the struct). **However**, the struct vector itself **does** have a validity mask. The reason for this is that the child elements of a struct can be `NULL`, but the struct **itself** can also be `NULL`.

Lists

Lists are nested types that contain a single child type, repeated `x` times per row. Think of them like a variable-length array in C. The way to access list data using vectors is to access the child vector using the `duckdb_list_vector_get_child` method.

The `duckdb_vector_get_data` must be used to get the offsets and lengths of the lists stored as `duckdb_list_entry`, that can then be applied to the child vector.

```
typedef struct {
    uint64_t offset;
    uint64_t length;
} duckdb_list_entry;
```

Note that both list entries itself **and** any children stored in the lists can also be `NULL`. This must be checked using the validity mask again.

Arrays

Arrays are nested types that contain a single child type, repeated exactly `array_size` times per row. Think of them like a fixed-size array in C. Arrays work exactly the same as lists, **except** the length and offset of each entry is fixed. The fixed array size can be obtained by using `duckdb_array_type_array_size`. The data for entry n then resides at `offset = n * array_size` and always has `length = array_size`.

Note that much like lists, arrays can still be `NULL`, which must be checked using the validity mask.

Examples

Below are several full end-to-end examples of how to interact with vectors.

Example: Reading an int64 Vector with NULL Values

```
duckdb_database db;
duckdb_connection con;
duckdb_open(nullptr, &db);
duckdb_connect(db, &con);

duckdb_result res;

    }
    // get the number of rows from the data chunk
    idx_t row_count = duckdb_data_chunk_get_size(result);
    // get the struct column
    duckdb_vector struct_col = duckdb_data_chunk_get_vector(result, 0);
    uint64_t *struct_validity = duckdb_vector_get_validity(struct_col);
    // get the child columns of the struct
    duckdb_vector col1_vector = duckdb_struct_vector_get_child(struct_col, 0);
    int64_t *col1_data = (int64_t *) duckdb_vector_get_data(col1_vector);
    uint64_t *col1_validity = duckdb_vector_get_validity(col1_vector);

    duckdb_vector col2_vector = duckdb_struct_vector_get_child(struct_col, 1);
    int64_t *col2_data = (int64_t *) duckdb_vector_get_data(col2_vector);
    uint64_t *col2_validity = duckdb_vector_get_validity(col2_vector);

    // iterate over the rows
    for (idx_t row = 0; row < row_count; row++) {
        if (!duckdb_validity_row_is_valid(struct_validity, row)) {
            // entire struct is NULL
            printf("NULL\n");
            continue;
        }
        // read col1
        printf("{'col1': ");
        if (!duckdb_validity_row_is_valid(col1_validity, row)) {
            // col1 is NULL
            printf("NULL");
        } else {
            printf("%lld", col1_data[row]);
        }
        printf(", 'col2': ");
        if (!duckdb_validity_row_is_valid(col2_validity, row)) {
            // col2 is NULL
            printf("NULL");
        } else {
            printf("%lld", col2_data[row]);
        }
        printf("}\n");
    }
```

```
    duckdb_destroy_data_chunk(&result);
}
// clean-up
duckdb_destroy_result(&res);
duckdb_disconnect(&con);
duckdb_close(&db);
```

Example: Reading a List Vector

```
duckdb_database db;
duckdb_connection con;
duckdb_open(nullptr, &db);
duckdb_connect(db, &con);

duckdb_result res;
duckdb_query(con, "SELECT CASE WHEN i % 5 = 0 THEN NULL WHEN i % 2 = 0 THEN [i, i + 1] ELSE [i * 42,
NULL, i * 84] END FROM range(10) t(i)", &res);

// iterate until result is exhausted
while (true) {
    duckdb_data_chunk result = duckdb_fetch_chunk(res);
    if (!result) {
        // result is exhausted
        break;
    }
    // get the number of rows from the data chunk
    idx_t row_count = duckdb_data_chunk_get_size(result);
    // get the list column
    duckdb_vector list_col = duckdb_data_chunk_get_vector(result, 0);
    duckdb_list_entry *list_data = (duckdb_list_entry *) duckdb_vector_get_data(list_col);
    uint64_t *list_validity = duckdb_vector_get_validity(list_col);
    // get the child column of the list
    duckdb_vector list_child = duckdb_list_vector_get_child(list_col);
    int64_t *child_data = (int64_t *) duckdb_vector_get_data(list_child);
    uint64_t *child_validity = duckdb_vector_get_validity(list_child);

    // iterate over the rows
    for (idx_t row = 0; row < row_count; row++) {
        if (!duckdb_validity_row_is_valid(list_validity, row)) {
            // entire list is NULL
            printf("NULL\n");
            continue;
        }
        // read the list offsets for this row
        duckdb_list_entry list = list_data[row];
        printf("[");
        for (idx_t child_idx = list.offset; child_idx < list.offset + list.length; child_idx++) {
            if (child_idx > list.offset) {
                printf(", ");
            }
            if (!duckdb_validity_row_is_valid(child_validity, child_idx)) {
                // col1 is NULL
                printf("NULL");
            } else {
                printf("%lld", child_data[child_idx]);
            }
        }
        printf("]\n");
    }
```

```
    duckdb_destroy_data_chunk(&result);
}
// clean-up
duckdb_destroy_result(&res);
duckdb_disconnect(&con);
duckdb_close(&db);
```

API Reference Overview

```

```

Validity Mask Functions

```
            bool duckdb_validity_row_is_valid(uint64_t *validity, idx_t row);
void duckdb_validity_set_row_validity(uint64_t *validity, idx_t row, bool valid);
void duckdb_validity_set_row_invalid(uint64_t *validity, idx_t row);
void duckdb_validity_set_row_valid(uint64_t *validity, idx_t row);
```

`duckdb_create_vector` Creates a flat vector. Must be destroyed with `duckdb_destroy_vector`.

Syntax

```
            duckdb_vector duckdb_create_vector(
  duckdb_logical_type type,
  idx_t capacity
);
```

Parameters

- `type`: The logical type of the vector.
- `capacity`: The capacity of the vector.

Return Value The vector.

`duckdb_destroy_vector` Destroys the vector and de-allocates its memory.

Syntax

```
            void duckdb_destroy_vector(
  duckdb_vector *vector
);
```

Parameters

- `vector`: A pointer to the vector.

`duckdb_vector_get_column_type` Retrieves the column type of the specified vector.

The result must be destroyed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_vector_get_column_type(
  duckdb_vector vector
);
```

Parameters

- `vector`: The vector get the data from

Return Value The type of the vector

`duckdb_vector_get_data` Retrieves the data pointer of the vector.

The data pointer can be used to read or write values from the vector. How to read or write values depends on the type of the vector.

Syntax

```
            void *duckdb_vector_get_data(
  duckdb_vector vector
);
```

Parameters

- `vector`: The vector to get the data from

Return Value The data pointer

`duckdb_vector_get_validity` Retrieves the validity mask pointer of the specified vector.

If all values are valid, this function MIGHT return NULL!

The validity mask is a bitset that signifies null-ness within the data chunk. It is a series of uint64_t values, where each uint64_t value contains validity for 64 tuples. The bit is set to 1 if the value is valid (i.e., not NULL) or 0 if the value is invalid (i.e., NULL).

Validity of a specific value can be obtained like this:

idx_t entry_idx = row_idx / 64; idx_t idx_in_entry = row_idx % 64; bool is_valid = validity_mask[entry_idx] & (1 « idx_in_entry);

Alternatively, the (slower) duckdb_validity_row_is_valid function can be used.

Syntax

```
            uint64_t *duckdb_vector_get_validity(
  duckdb_vector vector
);
```

Parameters

- `vector`: The vector to get the data from

Return Value The pointer to the validity mask, or NULL if no validity mask is present

`duckdb_vector_ensure_validity_writable` Ensures the validity mask is writable by allocating it.

After this function is called, `duckdb_vector_get_validity` will ALWAYS return non-NULL. This allows NULL values to be written to the vector, regardless of whether a validity mask was present before.

Syntax

```
            void duckdb_vector_ensure_validity_writable(
  duckdb_vector vector
);
```

Parameters

- `vector`: The vector to alter

`duckdb_vector_assign_string_element` Assigns a string element in the vector at the specified location.

Syntax

```
            void duckdb_vector_assign_string_element(
  duckdb_vector vector,
  idx_t index,
  const char *str
);
```

Parameters

- `vector`: The vector to alter
- `index`: The row position in the vector to assign the string to
- `str`: The null-terminated string

`duckdb_vector_assign_string_element_len` Assigns a string element in the vector at the specified location. You may also use this function to assign BLOBs.

Syntax

```
            void duckdb_vector_assign_string_element_len(
  duckdb_vector vector,
  idx_t index,
  const char *str,
  idx_t str_len
);
```

Parameters

- `vector`: The vector to alter
- `index`: The row position in the vector to assign the string to
- `str`: The string
- `str_len`: The length of the string (in bytes)

`duckdb_list_vector_get_child` Retrieves the child vector of a list vector.

The resulting vector is valid as long as the parent vector is valid.

Syntax

```
duckdb_vector duckdb_list_vector_get_child(
  duckdb_vector vector
);
```

Parameters

- `vector`: The vector

Return Value The child vector

`duckdb_list_vector_get_size` Returns the size of the child vector of the list.

Syntax

```
idx_t duckdb_list_vector_get_size(
  duckdb_vector vector
);
```

Parameters

- `vector`: The vector

Return Value The size of the child list

`duckdb_list_vector_set_size` Sets the total size of the underlying child-vector of a list vector.

Syntax

```
duckdb_state duckdb_list_vector_set_size(
  duckdb_vector vector,
  idx_t size
);
```

Parameters

- `vector`: The list vector.
- `size`: The size of the child list.

Return Value The duckdb state. Returns DuckDBError if the vector is nullptr.

`duckdb_list_vector_reserve` Sets the total capacity of the underlying child-vector of a list.

After calling this method, you must call `duckdb_vector_get_validity` and `duckdb_vector_get_data` to obtain current data and validity pointers

Syntax

```
            duckdb_state duckdb_list_vector_reserve(
  duckdb_vector vector,
  idx_t required_capacity
);
```

Parameters

- `vector`: The list vector.
- `required_capacity`: the total capacity to reserve.

Return Value The duckdb state. Returns DuckDBError if the vector is nullptr.

`duckdb_struct_vector_get_child` Retrieves the child vector of a struct vector. The resulting vector is valid as long as the parent vector is valid.

Syntax

```
            duckdb_vector duckdb_struct_vector_get_child(
  duckdb_vector vector,
  idx_t index
);
```

Parameters

- `vector`: The vector
- `index`: The child index

Return Value The child vector

`duckdb_array_vector_get_child` Retrieves the child vector of an array vector. The resulting vector is valid as long as the parent vector is valid. The resulting vector has the size of the parent vector multiplied by the array size.

Syntax

```
            duckdb_vector duckdb_array_vector_get_child(
  duckdb_vector vector
);
```

Parameters

- `vector`: The vector

Return Value The child vector

`duckdb_slice_vector` Slice a vector with a selection vector. The length of the selection vector must be less than or equal to the length of the vector. Turns the vector into a dictionary vector.

Syntax

```
            void duckdb_slice_vector(
  duckdb_vector vector,
  duckdb_selection_vector sel,
  idx_t len
);
```

Parameters

- `vector`: The vector to slice.
- `sel`: The selection vector.
- `len`: The length of the selection vector.

`duckdb_vector_copy_sel` Copy the src vector to the dst with a selection vector that identifies which indices to copy.

Syntax

```
            void duckdb_vector_copy_sel(
  duckdb_vector src,
  duckdb_vector dst,
  duckdb_selection_vector sel,
  idx_t src_count,
  idx_t src_offset,
  idx_t dst_offset
);
```

Parameters

- `src`: The vector to copy from.
- `dst`: The vector to copy to.
- `sel`: The selection vector. The length of the selection vector should not be more than the length of the src vector
- `src_count`: The number of entries from selection vector to copy. Think of this as the effective length of the selection vector starting from index 0
- `src_offset`: The offset in the selection vector to copy from (important: actual number of items copied = src_count - src_offset).
- `dst_offset`: The offset in the dst vector to start copying to.

`duckdb_vector_reference_value` Copies the value from `value` to `vector`.

Syntax

```
            void duckdb_vector_reference_value(
  duckdb_vector vector,
  duckdb_value value
);
```

Parameters

- `vector`: The receiving vector.
- `value`: The value to copy into the vector.

`duckdb_vector_reference_vector` Changes `to_vector` to reference ‘from_vector. After, the vectors share ownership of the data.

Syntax

```
            void duckdb_vector_reference_vector(
  duckdb_vector to_vector,
  duckdb_vector from_vector
);
```

Parameters

- `to_vector`: The receiving vector.
- `from_vector`: The vector to reference.

`duckdb_validity_row_is_valid` Returns whether or not a row is valid (i.e., not NULL) in the given validity mask.

Syntax

```
            bool duckdb_validity_row_is_valid(
  uint64_t *validity,
  idx_t row
);
```

Parameters

- `validity`: The validity mask, as obtained through `duckdb_vector_get_validity`
- `row`: The row index

Return Value true if the row is valid, false otherwise

`duckdb_validity_set_row_validity` In a validity mask, sets a specific row to either valid or invalid.

Note that `duckdb_vector_ensure_validity_writable` should be called before calling `duckdb_vector_get_validity`, to ensure that there is a validity mask to write to.

Syntax

```
            void duckdb_validity_set_row_validity(
  uint64_t *validity,
  idx_t row,
  bool valid
);
```

Parameters

- `validity`: The validity mask, as obtained through `duckdb_vector_get_validity`.
- `row`: The row index
- `valid`: Whether or not to set the row to valid, or invalid

`duckdb_validity_set_row_invalid` In a validity mask, sets a specific row to invalid.

Equivalent to `duckdb_validity_set_row_validity` with valid set to false.

Syntax

```
            void duckdb_validity_set_row_invalid(
  uint64_t *validity,
  idx_t row
);
```

Parameters

- `validity`: The validity mask
- `row`: The row index

`duckdb_validity_set_row_valid` In a validity mask, sets a specific row to valid.

Equivalent to `duckdb_validity_set_row_validity` with valid set to true.

Syntax

```
            void duckdb_validity_set_row_valid(
  uint64_t *validity,
  idx_t row
);
```

Parameters

- `validity`: The validity mask
- `row`: The row index

Values

The value class represents a single value of any type.

API Reference Overview

```
            void duckdb_destroy_value(duckdb_value *value);
duckdb_value duckdb_create_varchar(const char *text);
duckdb_value duckdb_create_varchar_length(const char *text, idx_t length);

duckdb_bit duckdb_get_bit(duckdb_value val);
duckdb_uhugeint duckdb_get_uuid(duckdb_value val);
char *duckdb_get_varchar(duckdb_value value);
duckdb_value duckdb_create_struct_value(duckdb_logical_type type, duckdb_value *values);
duckdb_value duckdb_create_list_value(duckdb_logical_type type, duckdb_value *values, idx_t value_
count);
duckdb_value duckdb_create_array_value(duckdb_logical_type type, duckdb_value *values, idx_t value_
count);
duckdb_value duckdb_create_map_value(duckdb_logical_type map_type, duckdb_value *keys, duckdb_value
*values, idx_t entry_count);
duckdb_value duckdb_create_union_value(duckdb_logical_type union_type, idx_t tag_index, duckdb_value
value);
idx_t duckdb_get_map_size(duckdb_value value);
duckdb_value duckdb_get_map_key(duckdb_value value, idx_t index);
duckdb_value duckdb_get_map_value(duckdb_value value, idx_t index);
bool duckdb_is_null_value(duckdb_value value);
duckdb_value duckdb_create_null_value();
idx_t duckdb_get_list_size(duckdb_value value);
duckdb_value duckdb_get_list_child(duckdb_value value, idx_t index);
duckdb_value duckdb_create_enum_value(duckdb_logical_type type, uint64_t value);
uint64_t duckdb_get_enum_value(duckdb_value value);
duckdb_value duckdb_get_struct_child(duckdb_value value, idx_t index);
```

```
char *duckdb_value_to_string(duckdb_value value);
```

`duckdb_destroy_value` Destroys the value and de-allocates all memory allocated for that type.

Syntax

```
            void duckdb_destroy_value(
  duckdb_value *value
);
```

Parameters

- `value`: The value to destroy.

`duckdb_create_varchar` Creates a value from a null-terminated string

Syntax

```
            duckdb_value duckdb_create_varchar(
  const char *text
);
```

Parameters

- `text`: The null-terminated string

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_varchar_length` Creates a value from a string

Syntax

```
            duckdb_value duckdb_create_varchar_length(
  const char *text,
  idx_t length
);
```

Parameters

- `text`: The text
- `length`: The length of the text

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_bool` Creates a value from a boolean

Syntax

```
            duckdb_value duckdb_create_bool(
  bool input
);
```

Parameters

- `input`: The boolean value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_int8` Creates a value from an int8_t (a tinyint)

Syntax

```
            duckdb_value duckdb_create_int8(
  int8_t input
);
```

Parameters

- `input`: The tinyint value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_uint8` Creates a value from a uint8_t (a utinyint)

Syntax

```
            duckdb_value duckdb_create_uint8(
  uint8_t input
);
```

Parameters

- `input`: The utinyint value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_int16` Creates a value from an int16_t (a smallint)

Syntax

```
            duckdb_value duckdb_create_int16(
  int16_t input
);
```

Parameters

- `input`: The smallint value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_uint16` Creates a value from a uint16_t (a usmallint)

Syntax

```
            duckdb_value duckdb_create_uint16(
  uint16_t input
);
```

Parameters

- `input`: The usmallint value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_int32` Creates a value from an int32_t (an integer)

Syntax

```
            duckdb_value duckdb_create_int32(
  int32_t input
);
```

Parameters

- `input`: The integer value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_uint32` Creates a value from a uint32_t (a uinteger)

Syntax

```
            duckdb_value duckdb_create_uint32(
  uint32_t input
);
```

Parameters

- `input`: The uinteger value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_uint64` Creates a value from a uint64_t (a ubigint)

Syntax

```
            duckdb_value duckdb_create_uint64(
  uint64_t input
);
```

Parameters

- `input`: The ubigint value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_int64` Creates a value from an int64

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

Syntax

```
            duckdb_value duckdb_create_int64(
  int64_t val
);
```

`duckdb_create_hugeint` Creates a value from a hugeint

Syntax

```
            duckdb_value duckdb_create_hugeint(
  duckdb_hugeint input
);
```

Parameters

- `input`: The hugeint value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_uhugeint` Creates a value from a uhugeint

Syntax

```
            duckdb_value duckdb_create_uhugeint(
  duckdb_uhugeint input
);
```

Parameters

- `input`: The uhugeint value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_bignum` Creates a BIGNUM value from a duckdb_bignum

Syntax

```
            duckdb_value duckdb_create_bignum(
  duckdb_bignum input
);
```

Parameters

- `input`: The duckdb_bignum value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_decimal` Creates a DECIMAL value from a duckdb_decimal

Syntax

```
            duckdb_value duckdb_create_decimal(
  duckdb_decimal input
);
```

Parameters

- `input`: The duckdb_decimal value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_float` Creates a value from a float

Syntax

```
            duckdb_value duckdb_create_float(
  float input
);
```

Parameters

- `input`: The float value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_double` Creates a value from a double

Syntax

```
            duckdb_value duckdb_create_double(
  double input
);
```

Parameters

- `input`: The double value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_date` Creates a value from a date

Syntax

```
            duckdb_value duckdb_create_date(
  duckdb_date input
);
```

Parameters

- `input`: The date value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_time` Creates a value from a time

Syntax

```
            duckdb_value duckdb_create_time(
  duckdb_time input
);
```

Parameters

- `input`: The time value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_time_ns` Creates a value from a time_ns

Syntax

```
            duckdb_value duckdb_create_time_ns(
  duckdb_time_ns input
);
```

Parameters

- `input`: The time value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_time_tz_value` Creates a value from a time_tz. Not to be confused with `duckdb_create_time_tz`, which creates a duckdb_time_tz_t.

Syntax

```
            duckdb_value duckdb_create_time_tz_value(
  duckdb_time_tz value
);
```

Parameters

- `value`: The time_tz value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_timestamp` Creates a TIMESTAMP value from a duckdb_timestamp

Syntax

```
            duckdb_value duckdb_create_timestamp(
  duckdb_timestamp input
);
```

Parameters

- `input`: The duckdb_timestamp value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_timestamp_tz` Creates a TIMESTAMP_TZ value from a duckdb_timestamp

Syntax

```
            duckdb_value duckdb_create_timestamp_tz(
  duckdb_timestamp input
);
```

Parameters

- `input`: The duckdb_timestamp value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_timestamp_s` Creates a TIMESTAMP_S value from a duckdb_timestamp_s

Syntax

```
            duckdb_value duckdb_create_timestamp_s(
  duckdb_timestamp_s input
);
```

Parameters

- `input`: The duckdb_timestamp_s value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_timestamp_ms` Creates a TIMESTAMP_MS value from a duckdb_timestamp_ms

Syntax

```
            duckdb_value duckdb_create_timestamp_ms(
  duckdb_timestamp_ms input
);
```

Parameters

- `input`: The duckdb_timestamp_ms value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_timestamp_ns` Creates a TIMESTAMP_NS value from a duckdb_timestamp_ns

Syntax

```
            duckdb_value duckdb_create_timestamp_ns(
  duckdb_timestamp_ns input
);
```

Parameters

- `input`: The duckdb_timestamp_ns value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_interval` Creates a value from an interval

Syntax

```
            duckdb_value duckdb_create_interval(
  duckdb_interval input
);
```

Parameters

- `input`: The interval value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_blob` Creates a value from a blob

Syntax

```
            duckdb_value duckdb_create_blob(
  const uint8_t *data,
  idx_t length
);
```

Parameters

- `data`: The blob data
- `length`: The length of the blob data

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_bit` Creates a BIT value from a duckdb_bit

Syntax

```
            duckdb_value duckdb_create_bit(
  duckdb_bit input
);
```

Parameters

- `input`: The duckdb_bit value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_uuid` Creates a UUID value from a uhugeint

Syntax

```
            duckdb_value duckdb_create_uuid(
  duckdb_uhugeint input
);
```

Parameters

- `input`: The duckdb_uhugeint containing the UUID

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_get_bool` Returns the boolean value of the given value.

Syntax

```
            bool duckdb_get_bool(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a boolean

Return Value A boolean, or false if the value cannot be converted

`duckdb_get_int8` Returns the int8_t value of the given value.

Syntax

```
            int8_t duckdb_get_int8(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a tinyint

Return Value A int8_t, or MinValue if the value cannot be converted

`duckdb_get_uint8` Returns the uint8_t value of the given value.

Syntax

```
            uint8_t duckdb_get_uint8(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a utinyint

Return Value A uint8_t, or MinValue if the value cannot be converted

`duckdb_get_int16` Returns the int16_t value of the given value.

Syntax

```
            int16_t duckdb_get_int16(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a smallint

Return Value A int16_t, or MinValue if the value cannot be converted

`duckdb_get_uint16` Returns the uint16_t value of the given value.

Syntax

```
            uint16_t duckdb_get_uint16(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a usmallint

Return Value A uint16_t, or MinValue if the value cannot be converted

`duckdb_get_int32` Returns the int32_t value of the given value.

Syntax

```
            int32_t duckdb_get_int32(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing an integer

Return Value A int32_t, or MinValue if the value cannot be converted

`duckdb_get_uint32` Returns the uint32_t value of the given value.

Syntax

```
            uint32_t duckdb_get_uint32(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a uinteger

Return Value A uint32_t, or MinValue if the value cannot be converted

`duckdb_get_int64` Returns the int64_t value of the given value.

Syntax

```
            int64_t duckdb_get_int64(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a bigint

Return Value A int64_t, or MinValue if the value cannot be converted

`duckdb_get_uint64` Returns the uint64_t value of the given value.

Syntax

```
            uint64_t duckdb_get_uint64(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a ubigint

Return Value A uint64_t, or MinValue if the value cannot be converted

`duckdb_get_hugeint` Returns the hugeint value of the given value.

Syntax

```
            duckdb_hugeint duckdb_get_hugeint(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a hugeint

Return Value A duckdb_hugeint, or MinValue if the value cannot be converted

`duckdb_get_uhugeint` Returns the uhugeint value of the given value.

Syntax

```
            duckdb_uhugeint duckdb_get_uhugeint(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a uhugeint

Return Value A duckdb_uhugeint, or MinValue if the value cannot be converted

`duckdb_get_bignum` Returns the duckdb_bignum value of the given value. The `data` field must be destroyed with `duckdb_free`.

Syntax

```
            duckdb_bignum duckdb_get_bignum(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a BIGNUM

Return Value A duckdb_bignum. The `data` field must be destroyed with `duckdb_free`.

`duckdb_get_decimal` Returns the duckdb_decimal value of the given value.

Syntax

```
            duckdb_decimal duckdb_get_decimal(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a DECIMAL

Return Value A duckdb_decimal, or MinValue if the value cannot be converted

`duckdb_get_float` Returns the float value of the given value.

Syntax

```
            float duckdb_get_float(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a float

Return Value A float, or NAN if the value cannot be converted

`duckdb_get_double` Returns the double value of the given value.

Syntax

```
            double duckdb_get_double(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a double

Return Value A double, or NAN if the value cannot be converted

`duckdb_get_date` Returns the date value of the given value.

Syntax

```
            duckdb_date duckdb_get_date(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a date

Return Value A duckdb_date, or MinValue if the value cannot be converted

`duckdb_get_time` Returns the time value of the given value.

Syntax

```
            duckdb_time duckdb_get_time(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a time

Return Value A duckdb_time, or MinValue if the value cannot be converted

`duckdb_get_time_ns` Returns the time_ns value of the given value.

Syntax

```
            duckdb_time_ns duckdb_get_time_ns(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a time_ns

Return Value A duckdb_time_ns, or MinValue if the value cannot be converted

`duckdb_get_time_tz` Returns the time_tz value of the given value.

Syntax

```
            duckdb_time_tz duckdb_get_time_tz(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a time_tz

Return Value A duckdb_time_tz, or MinValue if the value cannot be converted

`duckdb_get_timestamp` Returns the TIMESTAMP value of the given value.

Syntax

```
            duckdb_timestamp duckdb_get_timestamp(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a TIMESTAMP

Return Value A duckdb_timestamp, or MinValue if the value cannot be converted

`duckdb_get_timestamp_tz` Returns the TIMESTAMP_TZ value of the given value.

Syntax

```
            duckdb_timestamp duckdb_get_timestamp_tz(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a TIMESTAMP_TZ

Return Value A duckdb_timestamp, or MinValue if the value cannot be converted

`duckdb_get_timestamp_s` Returns the duckdb_timestamp_s value of the given value.

Syntax

```
            duckdb_timestamp_s duckdb_get_timestamp_s(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a TIMESTAMP_S

Return Value A duckdb_timestamp_s, or MinValue if the value cannot be converted

`duckdb_get_timestamp_ms` Returns the duckdb_timestamp_ms value of the given value.

Syntax

```
            duckdb_timestamp_ms duckdb_get_timestamp_ms(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a TIMESTAMP_MS

Return Value A duckdb_timestamp_ms, or MinValue if the value cannot be converted

`duckdb_get_timestamp_ns` Returns the duckdb_timestamp_ns value of the given value.

Syntax

```
            duckdb_timestamp_ns duckdb_get_timestamp_ns(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a TIMESTAMP_NS

Return Value A duckdb_timestamp_ns, or MinValue if the value cannot be converted

`duckdb_get_interval` Returns the interval value of the given value.

Syntax

```
            duckdb_interval duckdb_get_interval(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a interval

Return Value A duckdb_interval, or MinValue if the value cannot be converted

`duckdb_get_value_type` Returns the type of the given value. The type is valid as long as the value is not destroyed. The type itself must not be destroyed.

Syntax

```
            duckdb_logical_type duckdb_get_value_type(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value

Return Value A duckdb_logical_type.

`duckdb_get_blob` Returns the blob value of the given value.

Syntax

```
            duckdb_blob duckdb_get_blob(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a blob

Return Value A duckdb_blob

`duckdb_get_bit` Returns the duckdb_bit value of the given value. The `data` field must be destroyed with `duckdb_free`.

Syntax

```
            duckdb_bit duckdb_get_bit(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a BIT

Return Value A duckdb_bit

`duckdb_get_uuid` Returns a duckdb_uhugeint representing the UUID value of the given value.

Syntax

```
            duckdb_uhugeint duckdb_get_uuid(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a UUID

Return Value A duckdb_uhugeint representing the UUID value

`duckdb_get_varchar` Obtains a string representation of the given value. The result must be destroyed with `duckdb_free`.

Syntax

```
            char *duckdb_get_varchar(
  duckdb_value value
);
```

Parameters

- `value`: The value

Return Value The string value. This must be destroyed with `duckdb_free`.

`duckdb_create_struct_value` Creates a struct value from a type and an array of values. Must be destroyed with `duckdb_destroy_value`.

Syntax

```
            duckdb_value duckdb_create_struct_value(
  duckdb_logical_type type,
  duckdb_value *values
);
```

Parameters

- `type`: The type of the struct
- `values`: The values for the struct fields

Return Value The struct value, or nullptr, if any child type is `DUCKDB_TYPE_ANY` or `DUCKDB_TYPE_INVALID`.

`duckdb_create_list_value` Creates a list value from a child (element) type and an array of values of length `value_count`. Must be destroyed with `duckdb_destroy_value`.

Syntax

```
            duckdb_value duckdb_create_list_value(
  duckdb_logical_type type,
  duckdb_value *values,
  idx_t value_count
);
```

Parameters

- `type`: The type of the list
- `values`: The values for the list
- `value_count`: The number of values in the list

Return Value The list value, or nullptr, if the child type is `DUCKDB_TYPE_ANY` or `DUCKDB_TYPE_INVALID`.

`duckdb_create_array_value` Creates an array value from a child (element) type and an array of values of length `value_count`. Must be destroyed with `duckdb_destroy_value`.

Syntax

```
            duckdb_value duckdb_create_array_value(
  duckdb_logical_type type,
  duckdb_value *values,
  idx_t value_count
);
```

Parameters

- `type`: The type of the array
- `values`: The values for the array
- `value_count`: The number of values in the array

Return Value The array value, or nullptr, if the child type is `DUCKDB_TYPE_ANY` or `DUCKDB_TYPE_INVALID`.

`duckdb_create_map_value` Creates a map value from a map type and two arrays, one for the keys and one for the values, each of length `entry_count`. Must be destroyed with `duckdb_destroy_value`.

Syntax

```
            duckdb_value duckdb_create_map_value(
  duckdb_logical_type map_type,
  duckdb_value *keys,
  duckdb_value *values,
  idx_t entry_count
);
```

Parameters

- `map_type`: The map type
- `keys`: The keys of the map
- `values`: The values of the map
- `entry_count`: The number of entries (key-value pairs) in the map

Return Value The map value, or nullptr, if the parameters are invalid.

`duckdb_create_union_value` Creates a union value from a union type, a tag index and a value. Must be destroyed with `duckdb_destroy_value`.

Syntax

```
            duckdb_value duckdb_create_union_value(
  duckdb_logical_type union_type,
  idx_t tag_index,
  duckdb_value value
);
```

Parameters

- `union_type`: The union type
- `tag_index`: The index of the tag of the union
- `value`: The value of the union for that tag

Return Value The union value, or nullptr, if the parameters are invalid.

`duckdb_get_map_size` Returns the number of elements in a MAP value.

Syntax

```
            idx_t duckdb_get_map_size(
  duckdb_value value
);
```

Parameters

- `value`: The MAP value.

Return Value The number of elements in the map.

`duckdb_get_map_key` Returns the MAP key at index as a duckdb_value.

Syntax

```
            duckdb_value duckdb_get_map_key(
  duckdb_value value,
  idx_t index
);
```

Parameters

- `value`: The MAP value.
- `index`: The index of the key.

Return Value The key as a duckdb_value.

`duckdb_get_map_value` Returns the MAP value at index as a duckdb_value.

Syntax

```
            duckdb_value duckdb_get_map_value(
  duckdb_value value,
  idx_t index
);
```

Parameters

- `value`: The MAP value.
- `index`: The index of the value.

Return Value The value as a duckdb_value.

`duckdb_is_null_value` Returns whether the value's type is SQLNULL or not.

Syntax

```
            bool duckdb_is_null_value(
  duckdb_value value
);
```

Parameters

- `value`: The value to check.

Return Value True, if the value's type is SQLNULL, otherwise false.

`duckdb_create_null_value` Creates a value of type SQLNULL.

Return Value The duckdb_value representing SQLNULL. This must be destroyed with `duckdb_destroy_value`.

Syntax

```
            duckdb_value duckdb_create_null_value(

);
```

`duckdb_get_list_size` Returns the number of elements in a LIST value.

Syntax

```
            idx_t duckdb_get_list_size(
  duckdb_value value
);
```

Parameters

- `value`: The LIST value.

Return Value The number of elements in the list.

`duckdb_get_list_child` Returns the LIST child at index as a duckdb_value.

Syntax

```
            duckdb_value duckdb_get_list_child(
  duckdb_value value,
  idx_t index
);
```

Parameters

- `value`: The LIST value.
- `index`: The index of the child.

Return Value The child as a duckdb_value.

`duckdb_create_enum_value` Creates an enum value from a type and a value. Must be destroyed with `duckdb_destroy_value`.

Syntax

```
            duckdb_value duckdb_create_enum_value(
  duckdb_logical_type type,
  uint64_t value
);
```

Parameters

- `type`: The type of the enum
- `value`: The value for the enum

Return Value The enum value, or nullptr.

`duckdb_get_enum_value` Returns the enum value of the given value.

Syntax

```
            uint64_t duckdb_get_enum_value(
  duckdb_value value
);
```

Parameters

- `value`: A duckdb_value containing an enum

Return Value A uint64_t, or MinValue if the value cannot be converted

`duckdb_get_struct_child` Returns the STRUCT child at index as a duckdb_value.

Syntax

```
            duckdb_value duckdb_get_struct_child(
  duckdb_value value,
  idx_t index
);
```

Parameters

- `value`: The STRUCT value.
- `index`: The index of the child.

Return Value The child as a duckdb_value.

`duckdb_value_to_string` Returns the SQL string representation of the given value.

Syntax

```
            char *duckdb_value_to_string(
  duckdb_value value
);
```

Parameters

- `value`: A duckdb_value.

Return Value The SQL string representation as a null-terminated string. The result must be freed with `duckdb_free`.

Types

DuckDB is a strongly typed database system. As such, every column has a single type specified. This type is constant over the entire column. That is to say, a column that is labeled as an `INTEGER` column will only contain `INTEGER` values.

DuckDB also supports columns of composite types. For example, it is possible to define an array of integers (`INTEGER[]`). It is also possible to define types as arbitrary structs (`ROW(i INTEGER, j VARCHAR)`). For that reason, native DuckDB type objects are not mere enums, but a class that can potentially be nested.

Types in the C API are modeled using an enum (`duckdb_type`) and a complex class (`duckdb_logical_type`). For most primitive types, e.g., integers or varchars, the enum is sufficient. For more complex types, such as lists, structs or decimals, the logical type must be used.

```
typedef enum DUCKDB_TYPE {
  DUCKDB_TYPE_INVALID = 0,
  DUCKDB_TYPE_BOOLEAN = 1,
  DUCKDB_TYPE_TINYINT = 2,
  DUCKDB_TYPE_SMALLINT = 3,
  DUCKDB_TYPE_INTEGER = 4,
  DUCKDB_TYPE_BIGINT = 5,
  DUCKDB_TYPE_UTINYINT = 6,
  DUCKDB_TYPE_USMALLINT = 7,
  DUCKDB_TYPE_UINTEGER = 8,
  DUCKDB_TYPE_UBIGINT = 9,
  DUCKDB_TYPE_FLOAT = 10,
  DUCKDB_TYPE_DOUBLE = 11,
  DUCKDB_TYPE_TIMESTAMP = 12,
  DUCKDB_TYPE_DATE = 13,
  DUCKDB_TYPE_TIME = 14,
  DUCKDB_TYPE_INTERVAL = 15,
  DUCKDB_TYPE_HUGEINT = 16,
  DUCKDB_TYPE_UHUGEINT = 32,
  DUCKDB_TYPE_VARCHAR = 17,
  DUCKDB_TYPE_BLOB = 18,
  DUCKDB_TYPE_DECIMAL = 19,
  DUCKDB_TYPE_TIMESTAMP_S = 20,
  DUCKDB_TYPE_TIMESTAMP_MS = 21,
  DUCKDB_TYPE_TIMESTAMP_NS = 22,
  DUCKDB_TYPE_ENUM = 23,
  DUCKDB_TYPE_LIST = 24,
  DUCKDB_TYPE_STRUCT = 25,
  DUCKDB_TYPE_MAP = 26,
  DUCKDB_TYPE_ARRAY = 33,
  DUCKDB_TYPE_UUID = 27,
  DUCKDB_TYPE_UNION = 28,
  DUCKDB_TYPE_BIT = 29,
  DUCKDB_TYPE_TIME_TZ = 30,
  DUCKDB_TYPE_TIMESTAMP_TZ = 31,
} duckdb_type;
```

Functions

The enum type of a column in the result can be obtained using the `duckdb_column_type` function. The logical type of a column can be obtained using the `duckdb_column_logical_type` function.

`duckdb_value`

The `duckdb_value` functions will auto-cast values as required. For example, it is no problem to use `duckdb_value_double` on a column of type `duckdb_value_int32`. The value will be auto-cast and returned as a double. Note that in certain cases the cast may fail. For example, this can happen if we request a `duckdb_value_int8` and the value does not fit within an `int8` value. In this case, a default value will be returned (usually `0` or `nullptr`). The same default value will also be returned if the corresponding value is `NULL`.

The `duckdb_value_is_null` function can be used to check if a specific value is `NULL` or not.

The exception to the auto-cast rule is the `duckdb_value_varchar_internal` function. This function does not auto-cast and only works for VARCHAR columns. The reason this function exists is that the result does not need to be freed.

> `duckdb_value_varchar` and `duckdb_value_blob` require the result to be de-allocated using `duckdb_free`.

duckdb_fetch_chunk

The duckdb_fetch_chunk function can be used to read data chunks from a DuckDB result set, and is the most efficient way of reading data from a DuckDB result using the C API. It is also the only way of reading data of certain types from a DuckDB result. For example, the duckdb_value functions do not support structural reading of composite types (lists or structs) or more complex types like enums or decimals.

For more information about data chunks, see the documentation on data chunks.

API Reference Overview

```
            duckdb_data_chunk duckdb_result_get_chunk(duckdb_result result, idx_t chunk_index);
bool duckdb_result_is_streaming(duckdb_result result);
idx_t duckdb_result_chunk_count(duckdb_result result);
duckdb_result_type duckdb_result_return_type(duckdb_result result);
```

Date Time Timestamp Helpers

```
            duckdb_date_struct duckdb_from_date(duckdb_date date);
duckdb_date duckdb_to_date(duckdb_date_struct date);
bool duckdb_is_finite_date(duckdb_date date);
duckdb_time_struct duckdb_from_time(duckdb_time time);
duckdb_time_tz duckdb_create_time_tz(int64_t micros, int32_t offset);
duckdb_time_tz_struct duckdb_from_time_tz(duckdb_time_tz micros);
duckdb_time duckdb_to_time(duckdb_time_struct time);
duckdb_timestamp_struct duckdb_from_timestamp(duckdb_timestamp ts);
duckdb_timestamp duckdb_to_timestamp(duckdb_timestamp_struct ts);
bool duckdb_is_finite_timestamp(duckdb_timestamp ts);
bool duckdb_is_finite_timestamp_s(duckdb_timestamp_s ts);
bool duckdb_is_finite_timestamp_ms(duckdb_timestamp_ms ts);
bool duckdb_is_finite_timestamp_ns(duckdb_timestamp_ns ts);
```

Hugeint Helpers

```
            double duckdb_hugeint_to_double(duckdb_hugeint val);
duckdb_hugeint duckdb_double_to_hugeint(double val);
```

Decimal Helpers

```
            duckdb_decimal duckdb_double_to_decimal(double val, uint8_t width, uint8_t scale);
double duckdb_decimal_to_double(duckdb_decimal val);
```

Logical Type Interface

```
            duckdb_logical_type duckdb_create_logical_type(duckdb_type type);
char *duckdb_logical_type_get_alias(duckdb_logical_type type);
void duckdb_logical_type_set_alias(duckdb_logical_type type, const char *alias);
duckdb_logical_type duckdb_create_list_type(duckdb_logical_type type);
duckdb_logical_type duckdb_create_array_type(duckdb_logical_type type, idx_t array_size);
duckdb_logical_type duckdb_create_map_type(duckdb_logical_type key_type, duckdb_logical_type value_
type);
duckdb_logical_type duckdb_create_union_type(duckdb_logical_type *member_types, const char **member_
names, idx_t member_count);
duckdb_logical_type duckdb_create_struct_type(duckdb_logical_type *member_types, const char **member_
names, idx_t member_count);
```

```
duckdb_logical_type duckdb_create_enum_type(const char **member_names, idx_t member_count);
duckdb_logical_type duckdb_create_decimal_type(uint8_t width, uint8_t scale);
duckdb_type duckdb_get_type_id(duckdb_logical_type type);
uint8_t duckdb_decimal_width(duckdb_logical_type type);
uint8_t duckdb_decimal_scale(duckdb_logical_type type);
duckdb_type duckdb_decimal_internal_type(duckdb_logical_type type);
duckdb_type duckdb_enum_internal_type(duckdb_logical_type type);
uint32_t duckdb_enum_dictionary_size(duckdb_logical_type type);
char *duckdb_enum_dictionary_value(duckdb_logical_type type, idx_t index);
duckdb_logical_type duckdb_list_type_child_type(duckdb_logical_type type);
duckdb_logical_type duckdb_array_type_child_type(duckdb_logical_type type);
idx_t duckdb_array_type_array_size(duckdb_logical_type type);
duckdb_logical_type duckdb_map_type_key_type(duckdb_logical_type type);
duckdb_logical_type duckdb_map_type_value_type(duckdb_logical_type type);
idx_t duckdb_struct_type_child_count(duckdb_logical_type type);
char *duckdb_struct_type_child_name(duckdb_logical_type type, idx_t index);
duckdb_logical_type duckdb_struct_type_child_type(duckdb_logical_type type, idx_t index);
idx_t duckdb_union_type_member_count(duckdb_logical_type type);
char *duckdb_union_type_member_name(duckdb_logical_type type, idx_t index);
duckdb_logical_type duckdb_union_type_member_type(duckdb_logical_type type, idx_t index);
void duckdb_destroy_logical_type(duckdb_logical_type *type);
duckdb_state duckdb_register_logical_type(duckdb_connection con, duckdb_logical_type type, duckdb_
create_type_info info);
```

`duckdb_result_get_chunk`

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Fetches a data chunk from the duckdb_result. This function should be called repeatedly until the result is exhausted.

The result must be destroyed with `duckdb_destroy_data_chunk`.

This function supersedes all `duckdb_value` functions, as well as the `duckdb_column_data` and `duckdb_nullmask_data` functions. It results in significantly better performance, and should be preferred in newer code-bases.

If this function is used, none of the other result functions can be used and vice versa (i.e., this function cannot be mixed with the legacy result functions).

Use `duckdb_result_chunk_count` to figure out how many chunks there are in the result.

Syntax

```
           duckdb_data_chunk duckdb_result_get_chunk(
  duckdb_result result,
  idx_t chunk_index
);
```

Parameters

- `result`: The result object to fetch the data chunk from.
- `chunk_index`: The chunk index to fetch from.

Return Value The resulting data chunk. Returns `NULL` if the chunk index is out of bounds.

`duckdb_result_is_streaming`

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Checks if the type of the internal result is StreamQueryResult.

Syntax

```
            bool duckdb_result_is_streaming(
  duckdb_result result
);
```

Parameters

- `result`: The result object to check.

Return Value Whether or not the result object is of the type StreamQueryResult

`duckdb_result_chunk_count`

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Returns the number of data chunks present in the result.

Syntax

```
            idx_t duckdb_result_chunk_count(
  duckdb_result result
);
```

Parameters

- `result`: The result object

Return Value Number of data chunks present in the result.

`duckdb_result_return_type` Returns the return_type of the given result, or DUCKDB_RETURN_TYPE_INVALID on error

Syntax

```
            duckdb_result_type duckdb_result_return_type(
  duckdb_result result
);
```

Parameters

- `result`: The result object

Return Value The return_type

`duckdb_from_date` Decompose a `duckdb_date` object into year, month and date (stored as `duckdb_date_struct`).

Syntax

```
            duckdb_date_struct duckdb_from_date(
  duckdb_date date
);
```

Parameters

- `date`: The date object, as obtained from a `DUCKDB_TYPE_DATE` column.

Return Value The `duckdb_date_struct` with the decomposed elements.

`duckdb_to_date` Re-compose a `duckdb_date` from year, month and date (`duckdb_date_struct`).

Syntax

```
            duckdb_date duckdb_to_date(
  duckdb_date_struct date
);
```

Parameters

- `date`: The year, month and date stored in a `duckdb_date_struct`.

Return Value The `duckdb_date` element.

`duckdb_is_finite_date` Test a `duckdb_date` to see if it is a finite value.

Syntax

```
            bool duckdb_is_finite_date(
  duckdb_date date
);
```

Parameters

- `date`: The date object, as obtained from a `DUCKDB_TYPE_DATE` column.

Return Value True if the date is finite, false if it is ±infinity.

`duckdb_from_time` Decompose a `duckdb_time` object into hour, minute, second and microsecond (stored as `duckdb_time_struct`).

Syntax

```
            duckdb_time_struct duckdb_from_time(
  duckdb_time time
);
```

Parameters

- `time`: The time object, as obtained from a `DUCKDB_TYPE_TIME` column.

Return Value The `duckdb_time_struct` with the decomposed elements.

`duckdb_create_time_tz` Create a `duckdb_time_tz` object from micros and a timezone offset.

Syntax

```
            duckdb_time_tz duckdb_create_time_tz(
  int64_t micros,
  int32_t offset
);
```

Parameters

- `micros`: The microsecond component of the time.
- `offset`: The timezone offset component of the time.

Return Value The `duckdb_time_tz` element.

`duckdb_from_time_tz` Decompose a TIME_TZ objects into micros and a timezone offset.

Use `duckdb_from_time` to further decompose the micros into hour, minute, second and microsecond.

Syntax

```
            duckdb_time_tz_struct duckdb_from_time_tz(
  duckdb_time_tz micros
);
```

Parameters

- `micros`: The time object, as obtained from a `DUCKDB_TYPE_TIME_TZ` column.

`duckdb_to_time` Re-compose a `duckdb_time` from hour, minute, second and microsecond (`duckdb_time_struct`).

Syntax

```
            duckdb_time duckdb_to_time(
  duckdb_time_struct time
);
```

Parameters

- `time`: The hour, minute, second and microsecond in a `duckdb_time_struct`.

Return Value The `duckdb_time` element.

`duckdb_from_timestamp` Decompose a `duckdb_timestamp` object into a `duckdb_timestamp_struct`.

Syntax

```
            duckdb_timestamp_struct duckdb_from_timestamp(
  duckdb_timestamp ts
);
```

Parameters

- `ts`: The ts object, as obtained from a `DUCKDB_TYPE_TIMESTAMP` column.

Return Value The duckdb_timestamp_struct with the decomposed elements.

duckdb_to_timestamp Re-compose a duckdb_timestamp from a duckdb_timestamp_struct.

Syntax

```
            duckdb_timestamp duckdb_to_timestamp(
  duckdb_timestamp_struct ts
);
```

Parameters

- ts: The de-composed elements in a duckdb_timestamp_struct.

Return Value The duckdb_timestamp element.

duckdb_is_finite_timestamp Test a duckdb_timestamp to see if it is a finite value.

Syntax

```
            bool duckdb_is_finite_timestamp(
  duckdb_timestamp ts
);
```

Parameters

- ts: The duckdb_timestamp object, as obtained from a DUCKDB_TYPE_TIMESTAMP column.

Return Value True if the timestamp is finite, false if it is ±infinity.

duckdb_is_finite_timestamp_s Test a duckdb_timestamp_s to see if it is a finite value.

Syntax

```
            bool duckdb_is_finite_timestamp_s(
  duckdb_timestamp_s ts
);
```

Parameters

- ts: The duckdb_timestamp_s object, as obtained from a DUCKDB_TYPE_TIMESTAMP_S column.

Return Value True if the timestamp is finite, false if it is ±infinity.

duckdb_is_finite_timestamp_ms Test a duckdb_timestamp_ms to see if it is a finite value.

Syntax

```
            bool duckdb_is_finite_timestamp_ms(
  duckdb_timestamp_ms ts
);
```

Parameters

- `ts`: The duckdb_timestamp_ms object, as obtained from a `DUCKDB_TYPE_TIMESTAMP_MS` column.

Return Value True if the timestamp is finite, false if it is ±infinity.

`duckdb_is_finite_timestamp_ns` Test a `duckdb_timestamp_ns` to see if it is a finite value.

Syntax

```
            bool duckdb_is_finite_timestamp_ns(
  duckdb_timestamp_ns ts
);
```

Parameters

- `ts`: The duckdb_timestamp_ns object, as obtained from a `DUCKDB_TYPE_TIMESTAMP_NS` column.

Return Value True if the timestamp is finite, false if it is ±infinity.

`duckdb_hugeint_to_double` Converts a duckdb_hugeint object (as obtained from a `DUCKDB_TYPE_HUGEINT` column) into a double.

Syntax

```
            double duckdb_hugeint_to_double(
  duckdb_hugeint val
);
```

Parameters

- `val`: The hugeint value.

Return Value The converted `double` element.

`duckdb_double_to_hugeint` Converts a double value to a duckdb_hugeint object.

If the conversion fails because the double value is too big the result will be 0.

Syntax

```
            duckdb_hugeint duckdb_double_to_hugeint(
  double val
);
```

Parameters

- `val`: The double value.

Return Value The converted `duckdb_hugeint` element.

`duckdb_double_to_decimal` Converts a double value to a duckdb_decimal object.

If the conversion fails because the double value is too big, or the width/scale are invalid the result will be 0.

Syntax

```
            duckdb_decimal duckdb_double_to_decimal(
  double val,
  uint8_t width,
  uint8_t scale
);
```

Parameters

- `val`: The double value.

Return Value The converted `duckdb_decimal` element.

`duckdb_decimal_to_double` Converts a duckdb_decimal object (as obtained from a `DUCKDB_TYPE_DECIMAL` column) into a double.

Syntax

```
            double duckdb_decimal_to_double(
  duckdb_decimal val
);
```

Parameters

- `val`: The decimal value.

Return Value The converted `double` element.

`duckdb_create_logical_type` Creates a `duckdb_logical_type` from a primitive type. The resulting logical type must be destroyed with `duckdb_destroy_logical_type`.

Returns an invalid logical type, if type is: `DUCKDB_TYPE_INVALID`, `DUCKDB_TYPE_DECIMAL`, `DUCKDB_TYPE_ENUM`, `DUCKDB_TYPE_LIST`, `DUCKDB_TYPE_STRUCT`, `DUCKDB_TYPE_MAP`, `DUCKDB_TYPE_ARRAY`, or `DUCKDB_TYPE_UNION`.

Syntax

```
            duckdb_logical_type duckdb_create_logical_type(
  duckdb_type type
);
```

Parameters

- `type`: The primitive type to create.

Return Value The logical type.

`duckdb_logical_type_get_alias` Returns the alias of a duckdb_logical_type, if set, else `nullptr`. The result must be destroyed with `duckdb_free`.

Syntax

```
            char *duckdb_logical_type_get_alias(
  duckdb_logical_type type
);
```

Parameters

- `type`: The logical type

Return Value The alias or `nullptr`

`duckdb_logical_type_set_alias` Sets the alias of a duckdb_logical_type.

Syntax

```
            void duckdb_logical_type_set_alias(
  duckdb_logical_type type,
  const char *alias
);
```

Parameters

- `type`: The logical type
- `alias`: The alias to set

`duckdb_create_list_type` Creates a LIST type from its child type. The return type must be destroyed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_create_list_type(
  duckdb_logical_type type
);
```

Parameters

- `type`: The child type of the list

Return Value The logical type.

`duckdb_create_array_type` Creates an ARRAY type from its child type. The return type must be destroyed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_create_array_type(
  duckdb_logical_type type,
  idx_t array_size
);
```

Parameters

- `type`: The child type of the array.
- `array_size`: The number of elements in the array.

Return Value

The logical type.

`duckdb_create_map_type` Creates a MAP type from its key type and value type. The return type must be destroyed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_create_map_type(
  duckdb_logical_type key_type,
  duckdb_logical_type value_type
);
```

Parameters

- `key_type`: The map's key type.
- `value_type`: The map's value type.

Return Value

The logical type.

`duckdb_create_union_type` Creates a UNION type from the passed arrays. The return type must be destroyed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_create_union_type(
  duckdb_logical_type *member_types,
  const char **member_names,
  idx_t member_count
);
```

Parameters

- `member_types`: The array of union member types.
- `member_names`: The union member names.
- `member_count`: The number of union members.

Return Value

The logical type.

`duckdb_create_struct_type` Creates a STRUCT type based on the member types and names. The resulting type must be destroyed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_create_struct_type(
  duckdb_logical_type *member_types,
  const char **member_names,
  idx_t member_count
);
```

Parameters

- `member_types`: The array of types of the struct members.
- `member_names`: The array of names of the struct members.
- `member_count`: The number of members of the struct.

Return Value

The logical type.

`duckdb_create_enum_type` Creates an ENUM type from the passed member name array. The resulting type should be destroyed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_create_enum_type(
  const char **member_names,
  idx_t member_count
);
```

Parameters

- `member_names`: The array of names that the enum should consist of.
- `member_count`: The number of elements that were specified in the array.

Return Value

The logical type.

`duckdb_create_decimal_type` Creates a DECIMAL type with the specified width and scale. The resulting type should be destroyed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_create_decimal_type(
  uint8_t width,
  uint8_t scale
);
```

Parameters

- `width`: The width of the decimal type
- `scale`: The scale of the decimal type

Return Value

The logical type.

`duckdb_get_type_id` Retrieves the enum `duckdb_type` of a `duckdb_logical_type`.

Syntax

```
            duckdb_type duckdb_get_type_id(
  duckdb_logical_type type
);
```

Parameters

- `type`: The logical type.

Return Value The `duckdb_type` id.

`duckdb_decimal_width` Retrieves the width of a decimal type.

Syntax

```
            uint8_t duckdb_decimal_width(
  duckdb_logical_type type
);
```

Parameters

- `type`: The logical type object

Return Value The width of the decimal type

`duckdb_decimal_scale` Retrieves the scale of a decimal type.

Syntax

```
            uint8_t duckdb_decimal_scale(
  duckdb_logical_type type
);
```

Parameters

- `type`: The logical type object

Return Value The scale of the decimal type

`duckdb_decimal_internal_type` Retrieves the internal storage type of a decimal type.

Syntax

```
            duckdb_type duckdb_decimal_internal_type(
  duckdb_logical_type type
);
```

Parameters

- `type`: The logical type object

Return Value The internal type of the decimal type

`duckdb_enum_internal_type` Retrieves the internal storage type of an enum type.

Syntax

```
            duckdb_type duckdb_enum_internal_type(
  duckdb_logical_type type
);
```

Parameters

- `type`: The logical type object

Return Value The internal type of the enum type

`duckdb_enum_dictionary_size` Retrieves the dictionary size of the enum type.

Syntax

```
            uint32_t duckdb_enum_dictionary_size(
  duckdb_logical_type type
);
```

Parameters

- `type`: The logical type object

Return Value The dictionary size of the enum type

`duckdb_enum_dictionary_value` Retrieves the dictionary value at the specified position from the enum.

The result must be freed with `duckdb_free`.

Syntax

```
            char *duckdb_enum_dictionary_value(
  duckdb_logical_type type,
  idx_t index
);
```

Parameters

- `type`: The logical type object
- `index`: The index in the dictionary

Return Value The string value of the enum type. Must be freed with `duckdb_free`.

`duckdb_list_type_child_type` Retrieves the child type of the given LIST type. Also accepts MAP types. The result must be freed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_list_type_child_type(
  duckdb_logical_type type
);
```

Parameters

- `type`: The logical type, either LIST or MAP.

Return Value The child type of the LIST or MAP type.

`duckdb_array_type_child_type` Retrieves the child type of the given ARRAY type.

The result must be freed with `duckdb_destroy_logical_type`.

Syntax

```
duckdb_logical_type duckdb_array_type_child_type(
  duckdb_logical_type type
);
```

Parameters

- `type`: The logical type. Must be ARRAY.

Return Value The child type of the ARRAY type.

`duckdb_array_type_array_size` Retrieves the array size of the given array type.

Syntax

```
idx_t duckdb_array_type_array_size(
  duckdb_logical_type type
);
```

Parameters

- `type`: The logical type object

Return Value The fixed number of elements the values of this array type can store.

`duckdb_map_type_key_type` Retrieves the key type of the given map type.

The result must be freed with `duckdb_destroy_logical_type`.

Syntax

```
duckdb_logical_type duckdb_map_type_key_type(
  duckdb_logical_type type
);
```

Parameters

- `type`: The logical type object

Return Value The key type of the map type. Must be destroyed with `duckdb_destroy_logical_type`.

`duckdb_map_type_value_type` Retrieves the value type of the given map type.

The result must be freed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_map_type_value_type(
  duckdb_logical_type type
);
```

Parameters

- `type`: The logical type object

Return Value The value type of the map type. Must be destroyed with `duckdb_destroy_logical_type`.

`duckdb_struct_type_child_count` Returns the number of children of a struct type.

Syntax

```
            idx_t duckdb_struct_type_child_count(
  duckdb_logical_type type
);
```

Parameters

- `type`: The logical type object

Return Value The number of children of a struct type.

`duckdb_struct_type_child_name` Retrieves the name of the struct child.

The result must be freed with `duckdb_free`.

Syntax

```
            char *duckdb_struct_type_child_name(
  duckdb_logical_type type,
  idx_t index
);
```

Parameters

- `type`: The logical type object
- `index`: The child index

Return Value The name of the struct type. Must be freed with `duckdb_free`.

`duckdb_struct_type_child_type` Retrieves the child type of the given struct type at the specified index.

The result must be freed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_struct_type_child_type(
  duckdb_logical_type type,
  idx_t index
);
```

Parameters

- `type`: The logical type object
- `index`: The child index

Return Value The child type of the struct type. Must be destroyed with `duckdb_destroy_logical_type`.

`duckdb_union_type_member_count` Returns the number of members that the union type has.

Syntax

```
            idx_t duckdb_union_type_member_count(
  duckdb_logical_type type
);
```

Parameters

- `type`: The logical type (union) object

Return Value The number of members of a union type.

`duckdb_union_type_member_name` Retrieves the name of the union member.

The result must be freed with `duckdb_free`.

Syntax

```
            char *duckdb_union_type_member_name(
  duckdb_logical_type type,
  idx_t index
);
```

Parameters

- `type`: The logical type object
- `index`: The child index

Return Value The name of the union member. Must be freed with `duckdb_free`.

`duckdb_union_type_member_type` Retrieves the child type of the given union member at the specified index.

The result must be freed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_union_type_member_type(
  duckdb_logical_type type,
  idx_t index
);
```

Parameters

- `type`: The logical type object
- `index`: The child index

Return Value The child type of the union member. Must be destroyed with `duckdb_destroy_logical_type`.

`duckdb_destroy_logical_type` Destroys the logical type and de-allocates all memory allocated for that type.

Syntax

```
            void duckdb_destroy_logical_type(
  duckdb_logical_type *type
);
```

Parameters

- `type`: The logical type to destroy.

`duckdb_register_logical_type` Registers a custom type within the given connection. The type must have an alias

Syntax

```
            duckdb_state duckdb_register_logical_type(
  duckdb_connection con,
  duckdb_logical_type type,
  duckdb_create_type_info info
);
```

Parameters

- `con`: The connection to use
- `type`: The custom type to register

Return Value Whether or not the registration was successful.

Prepared Statements

A prepared statement is a parameterized query. The query is prepared with question marks (`?`) or dollar symbols (`$1`) indicating the parameters of the query. Values can then be bound to these parameters, after which the prepared statement can be executed using those parameters. A single query can be prepared once and executed many times.

Prepared statements are useful to:

- Easily supply parameters to functions while avoiding string concatenation/SQL injection attacks.
- Speeding up queries that will be executed many times with different parameters.

DuckDB supports prepared statements in the C API with the `duckdb_prepare` method. The `duckdb_bind` family of functions is used to supply values for subsequent execution of the prepared statement using `duckdb_execute_prepared`. After we are done with the prepared statement it can be cleaned up using the `duckdb_destroy_prepare` method.

Example

```
duckdb_prepared_statement stmt;
duckdb_result result;
if (duckdb_prepare(con, "INSERT INTO integers VALUES ($1, $2)", &stmt) == DuckDBError) {
    // handle error
}

duckdb_bind_int32(stmt, 1, 42); // the parameter index starts counting at 1!
duckdb_bind_int32(stmt, 2, 43);
// NULL as second parameter means no result set is requested
duckdb_execute_prepared(stmt, NULL);
duckdb_destroy_prepare(&stmt);

// we can also query result sets using prepared statements
if (duckdb_prepare(con, "SELECT * FROM integers WHERE i = ?", &stmt) == DuckDBError) {
    // handle error
}
duckdb_bind_int32(stmt, 1, 42);
duckdb_execute_prepared(stmt, &result);

// do something with result

// clean up
duckdb_destroy_result(&result);
duckdb_destroy_prepare(&stmt);
```

After calling `duckdb_prepare`, the prepared statement parameters can be inspected using `duckdb_nparams` and `duckdb_param_type`. In case the prepare fails, the error can be obtained through `duckdb_prepare_error`.

It is not required that the `duckdb_bind` family of functions matches the prepared statement parameter type exactly. The values will be auto-cast to the required value as required. For example, calling `duckdb_bind_int8` on a parameter type of `DUCKDB_TYPE_INTEGER` will work as expected.

> **Warning.** Do **not** use prepared statements to insert large amounts of data into DuckDB. Instead it is recommended to use the Appender.

API Reference Overview

```
           duckdb_state duckdb_prepare(duckdb_connection connection, const char *query, duckdb_
prepared_statement *out_prepared_statement);
void duckdb_destroy_prepare(duckdb_prepared_statement *prepared_statement);
const char *duckdb_prepare_error(duckdb_prepared_statement prepared_statement);
idx_t duckdb_nparams(duckdb_prepared_statement prepared_statement);
const char *duckdb_parameter_name(duckdb_prepared_statement prepared_statement, idx_t index);
duckdb_type duckdb_param_type(duckdb_prepared_statement prepared_statement, idx_t param_idx);
duckdb_logical_type duckdb_param_logical_type(duckdb_prepared_statement prepared_statement, idx_t param_
idx);
duckdb_state duckdb_clear_bindings(duckdb_prepared_statement prepared_statement);
duckdb_statement_type duckdb_prepared_statement_type(duckdb_prepared_statement statement);
idx_t duckdb_prepared_statement_column_count(duckdb_prepared_statement prepared_statement);
const char *duckdb_prepared_statement_column_name(duckdb_prepared_statement prepared_statement, idx_t
col_idx);
```

```
duckdb_logical_type duckdb_prepared_statement_column_logical_type(duckdb_prepared_statement prepared_
statement, idx_t col_idx);
duckdb_type duckdb_prepared_statement_column_type(duckdb_prepared_statement prepared_statement, idx_t
col_idx);
```

`duckdb_prepare` Create a prepared statement object from a query.

Note that after calling `duckdb_prepare`, the prepared statement should always be destroyed using `duckdb_destroy_prepare`, even if the prepare fails.

If the prepare fails, `duckdb_prepare_error` can be called to obtain the reason why the prepare failed.

Syntax

```
            duckdb_state duckdb_prepare(
  duckdb_connection connection,
  const char *query,
  duckdb_prepared_statement *out_prepared_statement
);
```

Parameters

- `connection`: The connection object
- `query`: The SQL query to prepare
- `out_prepared_statement`: The resulting prepared statement object

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_destroy_prepare` Closes the prepared statement and de-allocates all memory allocated for the statement.

Syntax

```
            void duckdb_destroy_prepare(
  duckdb_prepared_statement *prepared_statement
);
```

Parameters

- `prepared_statement`: The prepared statement to destroy.

`duckdb_prepare_error` Returns the error message associated with the given prepared statement. If the prepared statement has no error message, this returns `nullptr` instead.

The error message should not be freed. It will be de-allocated when `duckdb_destroy_prepare` is called.

Syntax

```
            const char *duckdb_prepare_error(
  duckdb_prepared_statement prepared_statement
);
```

Parameters

- `prepared_statement`: The prepared statement to obtain the error from.

Return Value The error message, or `nullptr` if there is none.

`duckdb_nparams` Returns the number of parameters that can be provided to the given prepared statement.

Returns 0 if the query was not successfully prepared.

Syntax

```
            idx_t duckdb_nparams(
  duckdb_prepared_statement prepared_statement
);
```

Parameters

- `prepared_statement`: The prepared statement to obtain the number of parameters for.

`duckdb_parameter_name` Returns the name used to identify the parameter The returned string should be freed using `duckdb_free`.

Returns NULL if the index is out of range for the provided prepared statement.

Syntax

```
            const char *duckdb_parameter_name(
  duckdb_prepared_statement prepared_statement,
  idx_t index
);
```

Parameters

- `prepared_statement`: The prepared statement for which to get the parameter name from.

`duckdb_param_type` Returns the parameter type for the parameter at the given index.

Returns `DUCKDB_TYPE_INVALID` if the parameter index is out of range or the statement was not successfully prepared.

Syntax

```
            duckdb_type duckdb_param_type(
  duckdb_prepared_statement prepared_statement,
  idx_t param_idx
);
```

Parameters

- `prepared_statement`: The prepared statement.
- `param_idx`: The parameter index.

Return Value The parameter type

`duckdb_param_logical_type` Returns the logical type for the parameter at the given index.

Returns `nullptr` if the parameter index is out of range or the statement was not successfully prepared.

The return type of this call should be destroyed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_param_logical_type(
  duckdb_prepared_statement prepared_statement,
  idx_t param_idx
);
```

Parameters

- `prepared_statement`: The prepared statement.
- `param_idx`: The parameter index.

Return Value The logical type of the parameter

`duckdb_clear_bindings` Clear the params bind to the prepared statement.

Syntax

```
            duckdb_state duckdb_clear_bindings(
  duckdb_prepared_statement prepared_statement
);
```

`duckdb_prepared_statement_type` Returns the statement type of the statement to be executed

Syntax

```
            duckdb_statement_type duckdb_prepared_statement_type(
  duckdb_prepared_statement statement
);
```

Parameters

- `statement`: The prepared statement.

Return Value duckdb_statement_type value or DUCKDB_STATEMENT_TYPE_INVALID

`duckdb_prepared_statement_column_count` Returns the number of columns present in the result of the prepared statement. If any of the column types are invalid, the result will be 1.

Syntax

```
            idx_t duckdb_prepared_statement_column_count(
  duckdb_prepared_statement prepared_statement
);
```

Parameters

- `prepared_statement`: The prepared statement.

Return Value The number of columns present in the result of the prepared statement.

`duckdb_prepared_statement_column_name` Returns the name of the specified column of the result of the prepared_statement. The returned string should be freed using `duckdb_free`.

Returns `nullptr` if the column is out of range.

Syntax

```
            const char *duckdb_prepared_statement_column_name(
  duckdb_prepared_statement prepared_statement,
  idx_t col_idx
);
```

Parameters

- `prepared_statement`: The prepared statement.
- `col_idx`: The column index.

Return Value The column name of the specified column.

`duckdb_prepared_statement_column_logical_type` Returns the column type of the specified column of the result of the prepared_statement.

Returns `DUCKDB_TYPE_INVALID` if the column is out of range. The return type of this call should be destroyed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_prepared_statement_column_logical_type(
  duckdb_prepared_statement prepared_statement,
  idx_t col_idx
);
```

Parameters

- `prepared_statement`: The prepared statement to fetch the column type from.
- `col_idx`: The column index.

Return Value The logical type of the specified column.

`duckdb_prepared_statement_column_type` Returns the column type of the specified column of the result of the prepared_statement.

Returns `DUCKDB_TYPE_INVALID` if the column is out of range.

Syntax

```
            duckdb_type duckdb_prepared_statement_column_type(
  duckdb_prepared_statement prepared_statement,
  idx_t col_idx
);
```

Parameters

- `prepared_statement`: The prepared statement to fetch the column type from.
- `col_idx`: The column index.

Return Value The type of the specified column.

Appender

Appenders are the most efficient way of loading data into DuckDB from within the C interface, and are recommended for fast data loading. The appender is much faster than using prepared statements or individual `INSERT INTO` statements.

Appends are made in row-wise format. For every column, a `duckdb_append_[type]` call should be made, after which the row should be finished by calling `duckdb_appender_end_row`. After all rows have been appended, `duckdb_appender_destroy` should be used to finalize the appender and clean up the resulting memory.

Note that `duckdb_appender_destroy` should always be called on the resulting appender, even if the function returns `DuckDBError`.

Example

```
duckdb_query(con, "CREATE TABLE people (id INTEGER, name VARCHAR)", NULL);

duckdb_appender appender;
if (duckdb_appender_create(con, NULL, "people", &appender) == DuckDBError) {
  // handle error
}
// append the first row (1, Mark)
duckdb_append_int32(appender, 1);
duckdb_append_varchar(appender, "Mark");
duckdb_appender_end_row(appender);

// append the second row (2, Hannes)
duckdb_append_int32(appender, 2);
duckdb_append_varchar(appender, "Hannes");
duckdb_appender_end_row(appender);

// finish appending and flush all the rows to the table
duckdb_appender_destroy(&appender);
```

API Reference Overview

```
            duckdb_state duckdb_appender_create(duckdb_connection connection, const char *schema, const
char *table, duckdb_appender *out_appender);
duckdb_state duckdb_appender_create_ext(duckdb_connection connection, const char *catalog, const char
*schema, const char *table, duckdb_appender *out_appender);
duckdb_state duckdb_appender_create_query(duckdb_connection connection, const char *query, idx_t column_
count, duckdb_logical_type *types, const char *table_name, const char **column_names, duckdb_appender
*out_appender);
idx_t duckdb_appender_column_count(duckdb_appender appender);
duckdb_logical_type duckdb_appender_column_type(duckdb_appender appender, idx_t col_idx);
const char *duckdb_appender_error(duckdb_appender appender);
duckdb_error_data duckdb_appender_error_data(duckdb_appender appender);
duckdb_state duckdb_appender_flush(duckdb_appender appender);
duckdb_state duckdb_appender_close(duckdb_appender appender);
duckdb_state duckdb_appender_destroy(duckdb_appender *appender);
duckdb_state duckdb_appender_add_column(duckdb_appender appender, const char *name);
duckdb_state duckdb_appender_clear_columns(duckdb_appender appender);
duckdb_state duckdb_appender_begin_row(duckdb_appender appender);
duckdb_state duckdb_appender_end_row(duckdb_appender appender);
duckdb_state duckdb_append_default(duckdb_appender appender);
```

```
duckdb_state duckdb_append_default_to_chunk(duckdb_appender appender, duckdb_data_chunk chunk, idx_t
col, idx_t row);
duckdb_state duckdb_append_bool(duckdb_appender appender, bool value);
duckdb_state duckdb_append_int8(duckdb_appender appender, int8_t value);
duckdb_state duckdb_append_int16(duckdb_appender appender, int16_t value);
duckdb_state duckdb_append_int32(duckdb_appender appender, int32_t value);
duckdb_state duckdb_append_int64(duckdb_appender appender, int64_t value);
duckdb_state duckdb_append_hugeint(duckdb_appender appender, duckdb_hugeint value);
duckdb_state duckdb_append_uint8(duckdb_appender appender, uint8_t value);
duckdb_state duckdb_append_uint16(duckdb_appender appender, uint16_t value);
duckdb_state duckdb_append_uint32(duckdb_appender appender, uint32_t value);
duckdb_state duckdb_append_uint64(duckdb_appender appender, uint64_t value);
duckdb_state duckdb_append_uhugeint(duckdb_appender appender, duckdb_uhugeint value);
duckdb_state duckdb_append_float(duckdb_appender appender, float value);
duckdb_state duckdb_append_double(duckdb_appender appender, double value);
duckdb_state duckdb_append_date(duckdb_appender appender, duckdb_date value);
duckdb_state duckdb_append_time(duckdb_appender appender, duckdb_time value);
duckdb_state duckdb_append_timestamp(duckdb_appender appender, duckdb_timestamp value);
duckdb_state duckdb_append_interval(duckdb_appender appender, duckdb_interval value);
duckdb_state duckdb_append_varchar(duckdb_appender appender, const char *val);
duckdb_state duckdb_append_varchar_length(duckdb_appender appender, const char *val, idx_t length);
duckdb_state duckdb_append_blob(duckdb_appender appender, const void *data, idx_t length);
duckdb_state duckdb_append_null(duckdb_appender appender);
duckdb_state duckdb_append_value(duckdb_appender appender, duckdb_value value);
duckdb_state duckdb_append_data_chunk(duckdb_appender appender, duckdb_data_chunk chunk);
```

`duckdb_appender_create` Creates an appender object.

Note that the object must be destroyed with `duckdb_appender_destroy`.

Syntax

```
            duckdb_state duckdb_appender_create(
  duckdb_connection connection,
  const char *schema,
  const char *table,
  duckdb_appender *out_appender
);
```

Parameters

- `connection`: The connection context to create the appender in.
- `schema`: The schema of the table to append to, or `nullptr` for the default schema.
- `table`: The table name to append to.
- `out_appender`: The resulting appender object.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_appender_create_ext` Creates an appender object.

Note that the object must be destroyed with `duckdb_appender_destroy`.

Syntax

```
            duckdb_state duckdb_appender_create_ext(
  duckdb_connection connection,
  const char *catalog,
  const char *schema,
  const char *table,
  duckdb_appender *out_appender
);
```

Parameters

- `connection`: The connection context to create the appender in.
- `catalog`: The catalog of the table to append to, or `nullptr` for the default catalog.
- `schema`: The schema of the table to append to, or `nullptr` for the default schema.
- `table`: The table name to append to.
- `out_appender`: The resulting appender object.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_appender_create_query` Creates an appender object that executes the given query with any data appended to it.

Note that the object must be destroyed with `duckdb_appender_destroy`.

Syntax

```
            duckdb_state duckdb_appender_create_query(
  duckdb_connection connection,
  const char *query,
  idx_t column_count,
  duckdb_logical_type *types,
  const char *table_name,
  const char **column_names,
  duckdb_appender *out_appender
);
```

Parameters

- `connection`: The connection context to create the appender in.
- `query`: The query to execute, can be an INSERT, DELETE, UPDATE or MERGE INTO statement.
- `column_count`: The number of columns to append.
- `types`: The types of the columns to append.
- `table_name`: (optionally) the table name used to refer to the appended data, defaults to "appended_data".
- `column_names`: (optionally) the list of column names, defaults to "col1", "col2", ...
- `out_appender`: The resulting appender object.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_appender_column_count` Returns the number of columns that belong to the appender. If there is no active column list, then this equals the table's physical columns.

Syntax

```
            idx_t duckdb_appender_column_count(
  duckdb_appender appender
);
```

Parameters

- `appender`: The appender to get the column count from.

Return Value The number of columns in the data chunks.

`duckdb_appender_column_type` Returns the type of the column at the specified index. This is either a type in the active column list, or the same type as a column in the receiving table.

Note: The resulting type must be destroyed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_appender_column_type(
  duckdb_appender appender,
  idx_t col_idx
);
```

Parameters

- `appender`: The appender to get the column type from.
- `col_idx`: The index of the column to get the type of.

Return Value The `duckdb_logical_type` of the column.

`duckdb_appender_error`

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release. Use duckdb_appender_error_data instead.

Returns the error message associated with the appender. If the appender has no error message, this returns `nullptr` instead.

The error message should not be freed. It will be de-allocated when `duckdb_appender_destroy` is called.

Syntax

```
            const char *duckdb_appender_error(
  duckdb_appender appender
);
```

Parameters

- `appender`: The appender to get the error from.

Return Value The error message, or `nullptr` if there is none.

`duckdb_appender_error_data` Returns the error data associated with the appender. Must be destroyed with duckdb_destroy_error_data.

Syntax

```
            duckdb_error_data duckdb_appender_error_data(
  duckdb_appender appender
);
```

Parameters

- `appender`: The appender to get the error data from.

Return Value The error data.

`duckdb_appender_flush` Flush the appender to the table, forcing the cache of the appender to be cleared. If flushing the data triggers a constraint violation or any other error, then all data is invalidated, and this function returns DuckDBError. It is not possible to append more values. Call duckdb_appender_error_data to obtain the error data followed by duckdb_appender_destroy to destroy the invalidated appender.

Syntax

```
duckdb_state duckdb_appender_flush(
  duckdb_appender appender
);
```

Parameters

- `appender`: The appender to flush.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_appender_close` Closes the appender by flushing all intermediate states and closing it for further appends. If flushing the data triggers a constraint violation or any other error, then all data is invalidated, and this function returns DuckDBError. Call duckdb_appender_error_data to obtain the error data followed by duckdb_appender_destroy to destroy the invalidated appender.

Syntax

```
duckdb_state duckdb_appender_close(
  duckdb_appender appender
);
```

Parameters

- `appender`: The appender to flush and close.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_appender_destroy` Closes the appender by flushing all intermediate states to the table and destroying it. By destroying it, this function de-allocates all memory associated with the appender. If flushing the data triggers a constraint violation, then all data is invalidated, and this function returns DuckDBError. Due to the destruction of the appender, it is no longer possible to obtain the specific error message with duckdb_appender_error. Therefore, call duckdb_appender_close before destroying the appender, if you need insights into the specific error.

Syntax

```
duckdb_state duckdb_appender_destroy(
  duckdb_appender *appender
);
```

Parameters

- `appender`: The appender to flush, close and destroy.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_appender_add_column` Appends a column to the active column list of the appender. Immediately flushes all previous data.

The active column list specifies all columns that are expected when flushing the data. Any non-active columns are filled with their default values, or NULL.

Syntax

```
            duckdb_state duckdb_appender_add_column(
  duckdb_appender appender,
  const char *name
);
```

Parameters

- `appender`: The appender to add the column to.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_appender_clear_columns` Removes all columns from the active column list of the appender, resetting the appender to treat all columns as active. Immediately flushes all previous data.

Syntax

```
            duckdb_state duckdb_appender_clear_columns(
  duckdb_appender appender
);
```

Parameters

- `appender`: The appender to clear the columns from.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_appender_begin_row` A nop function, provided for backwards compatibility reasons. Does nothing. Only `duckdb_appender_end_row` is required.

Syntax

```
            duckdb_state duckdb_appender_begin_row(
  duckdb_appender appender
);
```

`duckdb_appender_end_row` Finish the current row of appends. After end_row is called, the next row can be appended.

Syntax

```
            duckdb_state duckdb_appender_end_row(
  duckdb_appender appender
);
```

Parameters

- `appender`: The appender.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_append_default` Append a DEFAULT value (NULL if DEFAULT not available for column) to the appender.

Syntax

```
            duckdb_state duckdb_append_default(
  duckdb_appender appender
);
```

`duckdb_append_default_to_chunk` Append a DEFAULT value, at the specified row and column, (NULL if DEFAULT not available for column) to the chunk created from the specified appender. The default value of the column must be a constant value. Non-deterministic expressions like nextval('seq') or random() are not supported.

Syntax

```
            duckdb_state duckdb_append_default_to_chunk(
  duckdb_appender appender,
  duckdb_data_chunk chunk,
  idx_t col,
  idx_t row
);
```

Parameters

- `appender`: The appender to get the default value from.
- `chunk`: The data chunk to append the default value to.
- `col`: The chunk column index to append the default value to.
- `row`: The chunk row index to append the default value to.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_append_bool` Append a bool value to the appender.

Syntax

```
            duckdb_state duckdb_append_bool(
  duckdb_appender appender,
  bool value
);
```

`duckdb_append_int8` Append an int8_t value to the appender.

Syntax

```
            duckdb_state duckdb_append_int8(
  duckdb_appender appender,
  int8_t value
);
```

duckdb_append_int16 Append an int16_t value to the appender.

Syntax

```
            duckdb_state duckdb_append_int16(
  duckdb_appender appender,
  int16_t value
);
```

duckdb_append_int32 Append an int32_t value to the appender.

Syntax

```
            duckdb_state duckdb_append_int32(
  duckdb_appender appender,
  int32_t value
);
```

duckdb_append_int64 Append an int64_t value to the appender.

Syntax

```
            duckdb_state duckdb_append_int64(
  duckdb_appender appender,
  int64_t value
);
```

duckdb_append_hugeint Append a duckdb_hugeint value to the appender.

Syntax

```
            duckdb_state duckdb_append_hugeint(
  duckdb_appender appender,
  duckdb_hugeint value
);
```

duckdb_append_uint8 Append a uint8_t value to the appender.

Syntax

```
            duckdb_state duckdb_append_uint8(
  duckdb_appender appender,
  uint8_t value
);
```

duckdb_append_uint16 Append a uint16_t value to the appender.

Syntax

```
            duckdb_state duckdb_append_uint16(
  duckdb_appender appender,
  uint16_t value
);
```

`duckdb_append_uint32` Append a uint32_t value to the appender.

Syntax

```
            duckdb_state duckdb_append_uint32(
  duckdb_appender appender,
  uint32_t value
);
```

`duckdb_append_uint64` Append a uint64_t value to the appender.

Syntax

```
            duckdb_state duckdb_append_uint64(
  duckdb_appender appender,
  uint64_t value
);
```

`duckdb_append_uhugeint` Append a duckdb_uhugeint value to the appender.

Syntax

```
            duckdb_state duckdb_append_uhugeint(
  duckdb_appender appender,
  duckdb_uhugeint value
);
```

`duckdb_append_float` Append a float value to the appender.

Syntax

```
            duckdb_state duckdb_append_float(
  duckdb_appender appender,
  float value
);
```

`duckdb_append_double` Append a double value to the appender.

Syntax

```
            duckdb_state duckdb_append_double(
  duckdb_appender appender,
  double value
);
```

`duckdb_append_date` Append a duckdb_date value to the appender.

Syntax

```
            duckdb_state duckdb_append_date(
  duckdb_appender appender,
  duckdb_date value
);
```

`duckdb_append_time` Append a duckdb_time value to the appender.

Syntax

```
            duckdb_state duckdb_append_time(
  duckdb_appender appender,
  duckdb_time value
);
```

`duckdb_append_timestamp` Append a duckdb_timestamp value to the appender.

Syntax

```
            duckdb_state duckdb_append_timestamp(
  duckdb_appender appender,
  duckdb_timestamp value
);
```

`duckdb_append_interval` Append a duckdb_interval value to the appender.

Syntax

```
            duckdb_state duckdb_append_interval(
  duckdb_appender appender,
  duckdb_interval value
);
```

`duckdb_append_varchar` Append a varchar value to the appender.

Syntax

```
            duckdb_state duckdb_append_varchar(
  duckdb_appender appender,
  const char *val
);
```

`duckdb_append_varchar_length` Append a varchar value to the appender.

Syntax

```
            duckdb_state duckdb_append_varchar_length(
  duckdb_appender appender,
  const char *val,
  idx_t length
);
```

`duckdb_append_blob` Append a blob value to the appender.

Syntax

```
            duckdb_state duckdb_append_blob(
  duckdb_appender appender,
  const void *data,
  idx_t length
);
```

`duckdb_append_null` Append a NULL value to the appender (of any type).

Syntax

```
            duckdb_state duckdb_append_null(
  duckdb_appender appender
);
```

`duckdb_append_value` Append a duckdb_value to the appender.

Syntax

```
            duckdb_state duckdb_append_value(
  duckdb_appender appender,
  duckdb_value value
);
```

`duckdb_append_data_chunk` Appends a pre-filled data chunk to the specified appender. Attempts casting, if the data chunk types do not match the active appender types.

Syntax

```
            duckdb_state duckdb_append_data_chunk(
  duckdb_appender appender,
  duckdb_data_chunk chunk
);
```

Parameters

- `appender`: The appender to append to.
- `chunk`: The data chunk to append.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

Table Functions

The table function API can be used to define a table function that can then be called from within DuckDB in the `FROM` clause of a query.

API Reference Overview

```
            duckdb_table_function duckdb_create_table_function();
void duckdb_destroy_table_function(duckdb_table_function *table_function);
void duckdb_table_function_set_name(duckdb_table_function table_function, const char *name);
void duckdb_table_function_add_parameter(duckdb_table_function table_function, duckdb_logical_type
type);
void duckdb_table_function_add_named_parameter(duckdb_table_function table_function, const char *name,
duckdb_logical_type type);
void duckdb_table_function_set_extra_info(duckdb_table_function table_function, void *extra_info,
duckdb_delete_callback_t destroy);
void duckdb_table_function_set_bind(duckdb_table_function table_function, duckdb_table_function_bind_t
bind);
void duckdb_table_function_set_init(duckdb_table_function table_function, duckdb_table_function_init_t
init);
void duckdb_table_function_set_local_init(duckdb_table_function table_function, duckdb_table_function_
init_t init);
void duckdb_table_function_set_function(duckdb_table_function table_function, duckdb_table_function_t
function);
void duckdb_table_function_supports_projection_pushdown(duckdb_table_function table_function, bool
pushdown);
duckdb_state duckdb_register_table_function(duckdb_connection con, duckdb_table_function function);
```

Table Function Bind

```
            void *duckdb_bind_get_extra_info(duckdb_bind_info info);
void duckdb_table_function_get_client_context(duckdb_bind_info info, duckdb_client_context *out_
context);
void duckdb_bind_add_result_column(duckdb_bind_info info, const char *name, duckdb_logical_type type);
idx_t duckdb_bind_get_parameter_count(duckdb_bind_info info);
duckdb_value duckdb_bind_get_parameter(duckdb_bind_info info, idx_t index);
duckdb_value duckdb_bind_get_named_parameter(duckdb_bind_info info, const char *name);
void duckdb_bind_set_bind_data(duckdb_bind_info info, void *bind_data, duckdb_delete_callback_t
destroy);
void duckdb_bind_set_cardinality(duckdb_bind_info info, idx_t cardinality, bool is_exact);
void duckdb_bind_set_error(duckdb_bind_info info, const char *error);
```

Table Function Init

```
            void *duckdb_init_get_extra_info(duckdb_init_info info);
void *duckdb_init_get_bind_data(duckdb_init_info info);
void duckdb_init_set_init_data(duckdb_init_info info, void *init_data, duckdb_delete_callback_t
destroy);
idx_t duckdb_init_get_column_count(duckdb_init_info info);
idx_t duckdb_init_get_column_index(duckdb_init_info info, idx_t column_index);
void duckdb_init_set_max_threads(duckdb_init_info info, idx_t max_threads);
void duckdb_init_set_error(duckdb_init_info info, const char *error);
```

Table Function

```
            void *duckdb_function_get_extra_info(duckdb_function_info info);
void *duckdb_function_get_bind_data(duckdb_function_info info);
void *duckdb_function_get_init_data(duckdb_function_info info);
void *duckdb_function_get_local_init_data(duckdb_function_info info);
void duckdb_function_set_error(duckdb_function_info info, const char *error);
```

`duckdb_create_table_function` Creates a new empty table function.

The return value should be destroyed with `duckdb_destroy_table_function`.

Return Value The table function object.

Syntax

```
            duckdb_table_function duckdb_create_table_function(

);
```

`duckdb_destroy_table_function` Destroys the given table function object.

Syntax

```
            void duckdb_destroy_table_function(
  duckdb_table_function *table_function
);
```

Parameters

- `table_function`: The table function to destroy

`duckdb_table_function_set_name` Sets the name of the given table function.

Syntax

```
            void duckdb_table_function_set_name(
  duckdb_table_function table_function,
  const char *name
);
```

Parameters

- `table_function`: The table function
- `name`: The name of the table function

`duckdb_table_function_add_parameter` Adds a parameter to the table function.

Syntax

```
            void duckdb_table_function_add_parameter(
  duckdb_table_function table_function,
  duckdb_logical_type type
);
```

Parameters

- `table_function`: The table function.
- `type`: The parameter type. Cannot contain INVALID.

`duckdb_table_function_add_named_parameter` Adds a named parameter to the table function.

Syntax

```
            void duckdb_table_function_add_named_parameter(
  duckdb_table_function table_function,
  const char *name,
  duckdb_logical_type type
);
```

Parameters

- `table_function`: The table function.
- `name`: The parameter name.
- `type`: The parameter type. Cannot contain INVALID.

`duckdb_table_function_set_extra_info` Assigns extra information to the table function that can be fetched during binding, etc.

Syntax

```
            void duckdb_table_function_set_extra_info(
  duckdb_table_function table_function,
  void *extra_info,
  duckdb_delete_callback_t destroy
);
```

Parameters

- `table_function`: The table function
- `extra_info`: The extra information
- `destroy`: The callback that will be called to destroy the extra information (if any)

`duckdb_table_function_set_bind` Sets the bind function of the table function.

Syntax

```
            void duckdb_table_function_set_bind(
  duckdb_table_function table_function,
  duckdb_table_function_bind_t bind
);
```

Parameters

- `table_function`: The table function
- `bind`: The bind function

`duckdb_table_function_set_init` Sets the init function of the table function.

Syntax

```
            void duckdb_table_function_set_init(
  duckdb_table_function table_function,
  duckdb_table_function_init_t init
);
```

Parameters

- `table_function`: The table function
- `init`: The init function

`duckdb_table_function_set_local_init` Sets the thread-local init function of the table function.

Syntax

```
            void duckdb_table_function_set_local_init(
  duckdb_table_function table_function,
  duckdb_table_function_init_t init
);
```

Parameters

- `table_function`: The table function
- `init`: The init function

`duckdb_table_function_set_function` Sets the main function of the table function.

Syntax

```
            void duckdb_table_function_set_function(
  duckdb_table_function table_function,
  duckdb_table_function_t function
);
```

Parameters

- `table_function`: The table function
- `function`: The function

`duckdb_table_function_supports_projection_pushdown` Sets whether or not the given table function supports projection pushdown.

If this is set to true, the system will provide a list of all required columns in the `init` stage through the `duckdb_init_get_column_count` and `duckdb_init_get_column_index` functions. If this is set to false (the default), the system will expect all columns to be projected.

Syntax

```
            void duckdb_table_function_supports_projection_pushdown(
  duckdb_table_function table_function,
  bool pushdown
);
```

Parameters

- `table_function`: The table function
- `pushdown`: True if the table function supports projection pushdown, false otherwise.

`duckdb_register_table_function` Register the table function object within the given connection.

The function requires at least a name, a bind function, an init function and a main function.

If the function is incomplete or a function with this name already exists DuckDBError is returned.

Syntax

```
            duckdb_state duckdb_register_table_function(
  duckdb_connection con,
  duckdb_table_function function
);
```

Parameters

- `con`: The connection to register it in.
- `function`: The function pointer

Return Value Whether or not the registration was successful.

`duckdb_bind_get_extra_info` Retrieves the extra info of the function as set in `duckdb_table_function_set_extra_info`.

Syntax

```
            void *duckdb_bind_get_extra_info(
  duckdb_bind_info info
);
```

Parameters

- `info`: The info object

Return Value The extra info

`duckdb_table_function_get_client_context` Retrieves the client context of the bind info of a table function.

Syntax

```
            void duckdb_table_function_get_client_context(
  duckdb_bind_info info,
  duckdb_client_context *out_context
);
```

Parameters

- `info`: The bind info object of the table function.
- `out_context`: The client context of the bind info. Must be destroyed with `duckdb_destroy_client_context`.

`duckdb_bind_add_result_column` Adds a result column to the output of the table function.

Syntax

```
            void duckdb_bind_add_result_column(
  duckdb_bind_info info,
  const char *name,
  duckdb_logical_type type
);
```

Parameters

- `info`: The table function's bind info.
- `name`: The column name.
- `type`: The logical column type.

`duckdb_bind_get_parameter_count` Retrieves the number of regular (non-named) parameters to the function.

Syntax

```
            idx_t duckdb_bind_get_parameter_count(
  duckdb_bind_info info
);
```

Parameters

- `info`: The info object

Return Value The number of parameters

`duckdb_bind_get_parameter` Retrieves the parameter at the given index.

The result must be destroyed with `duckdb_destroy_value`.

Syntax

```
            duckdb_value duckdb_bind_get_parameter(
  duckdb_bind_info info,
  idx_t index
);
```

Parameters

- `info`: The info object
- `index`: The index of the parameter to get

Return Value The value of the parameter. Must be destroyed with `duckdb_destroy_value`.

`duckdb_bind_get_named_parameter` Retrieves a named parameter with the given name.

The result must be destroyed with `duckdb_destroy_value`.

Syntax

```
            duckdb_value duckdb_bind_get_named_parameter(
  duckdb_bind_info info,
  const char *name
);
```

Parameters

- `info`: The info object
- `name`: The name of the parameter

Return Value The value of the parameter. Must be destroyed with `duckdb_destroy_value`.

`duckdb_bind_set_bind_data` Sets the user-provided bind data in the bind object of the table function. This object can be retrieved again during execution.

Syntax

```
            void duckdb_bind_set_bind_data(
  duckdb_bind_info info,
  void *bind_data,
  duckdb_delete_callback_t destroy
);
```

Parameters

- `info`: The bind info of the table function.
- `bind_data`: The bind data object.
- `destroy`: The callback to destroy the bind data (if any).

`duckdb_bind_set_cardinality` Sets the cardinality estimate for the table function, used for optimization.

Syntax

```
            void duckdb_bind_set_cardinality(
  duckdb_bind_info info,
  idx_t cardinality,
  bool is_exact
);
```

Parameters

- `info`: The bind data object.
- `is_exact`: Whether or not the cardinality estimate is exact, or an approximation

`duckdb_bind_set_error` Report that an error has occurred while calling bind on a table function.

Syntax

```
            void duckdb_bind_set_error(
  duckdb_bind_info info,
  const char *error
);
```

Parameters

- `info`: The info object
- `error`: The error message

`duckdb_init_get_extra_info` Retrieves the extra info of the function as set in `duckdb_table_function_set_extra_info`.

Syntax

```
            void *duckdb_init_get_extra_info(
  duckdb_init_info info
);
```

Parameters

- `info`: The info object

Return Value The extra info

`duckdb_init_get_bind_data` Gets the bind data set by `duckdb_bind_set_bind_data` during the bind.

Note that the bind data should be considered as read-only. For tracking state, use the init data instead.

Syntax

```
            void *duckdb_init_get_bind_data(
  duckdb_init_info info
);
```

Parameters

- `info`: The info object

Return Value The bind data object

`duckdb_init_set_init_data` Sets the user-provided init data in the init object. This object can be retrieved again during execution.

Syntax

```
            void duckdb_init_set_init_data(
  duckdb_init_info info,
  void *init_data,
  duckdb_delete_callback_t destroy
);
```

Parameters

- `info`: The info object
- `init_data`: The init data object.
- `destroy`: The callback that will be called to destroy the init data (if any)

`duckdb_init_get_column_count` Returns the number of projected columns.

This function must be used if projection pushdown is enabled to figure out which columns to emit.

Syntax

```
            idx_t duckdb_init_get_column_count(
  duckdb_init_info info
);
```

Parameters

- `info`: The info object

Return Value The number of projected columns.

`duckdb_init_get_column_index` Returns the column index of the projected column at the specified position.

This function must be used if projection pushdown is enabled to figure out which columns to emit.

Syntax

```
            idx_t duckdb_init_get_column_index(
  duckdb_init_info info,
  idx_t column_index
);
```

Parameters

- `info`: The info object
- `column_index`: The index at which to get the projected column index, from 0..duckdb_init_get_column_count(info)

Return Value The column index of the projected column.

`duckdb_init_set_max_threads` Sets how many threads can process this table function in parallel (default: 1)

Syntax

```
            void duckdb_init_set_max_threads(
  duckdb_init_info info,
  idx_t max_threads
);
```

Parameters

- `info`: The info object
- `max_threads`: The maximum amount of threads that can process this table function

`duckdb_init_set_error` Report that an error has occurred while calling init.

Syntax

```
            void duckdb_init_set_error(
  duckdb_init_info info,
  const char *error
);
```

Parameters

- `info`: The info object
- `error`: The error message

`duckdb_function_get_extra_info` Retrieves the extra info of the function as set in `duckdb_table_function_set_extra_info`.

Syntax

```
            void *duckdb_function_get_extra_info(
  duckdb_function_info info
);
```

Parameters

- `info`: The info object

Return Value

The extra info

`duckdb_function_get_bind_data` Gets the table function's bind data set by `duckdb_bind_set_bind_data`.

Note that the bind data is read-only. For tracking state, use the init data instead.

Syntax

```
            void *duckdb_function_get_bind_data(
  duckdb_function_info info
);
```

Parameters

- `info`: The function info object.

Return Value

The bind data object.

`duckdb_function_get_init_data` Gets the init data set by `duckdb_init_set_init_data` during the init.

Syntax

```
            void *duckdb_function_get_init_data(
  duckdb_function_info info
);
```

Parameters

- `info`: The info object

Return Value The init data object

`duckdb_function_get_local_init_data` Gets the thread-local init data set by `duckdb_init_set_init_data` during the local_init.

Syntax

```
            void *duckdb_function_get_local_init_data(
  duckdb_function_info info
);
```

Parameters

- `info`: The info object

Return Value The init data object

`duckdb_function_set_error` Report that an error has occurred while executing the function.

Syntax

```
            void duckdb_function_set_error(
  duckdb_function_info info,
  const char *error
);
```

Parameters

- `info`: The info object
- `error`: The error message

Replacement Scans

The replacement scan API can be used to register a callback that is called when a table is read that does not exist in the catalog. For example, when a query such as `SELECT * FROM my_table` is executed and `my_table` does not exist, the replacement scan callback will be called with `my_table` as parameter. The replacement scan can then insert a table function with a specific parameter to replace the read of the table.

API Reference Overview

```
            void duckdb_add_replacement_scan(duckdb_database db, duckdb_replacement_callback_t
            replacement, void *extra_data, duckdb_delete_callback_t delete_callback);
void duckdb_replacement_scan_set_function_name(duckdb_replacement_scan_info info, const char *function_
name);
void duckdb_replacement_scan_add_parameter(duckdb_replacement_scan_info info, duckdb_value parameter);
void duckdb_replacement_scan_set_error(duckdb_replacement_scan_info info, const char *error);
```

`duckdb_add_replacement_scan` Add a replacement scan definition to the specified database.

Syntax

```
            void duckdb_add_replacement_scan(
  duckdb_database db,
  duckdb_replacement_callback_t replacement,
  void *extra_data,
  duckdb_delete_callback_t delete_callback
);
```

Parameters

- db: The database object to add the replacement scan to
- `replacement`: The replacement scan callback
- `extra_data`: Extra data that is passed back into the specified callback
- `delete_callback`: The delete callback to call on the extra data, if any

`duckdb_replacement_scan_set_function_name` Sets the replacement function name. If this function is called in the replacement callback, the replacement scan is performed. If it is not called, the replacement callback is not performed.

Syntax

```
            void duckdb_replacement_scan_set_function_name(
  duckdb_replacement_scan_info info,
  const char *function_name
);
```

Parameters

- `info`: The info object
- `function_name`: The function name to substitute.

`duckdb_replacement_scan_add_parameter` Adds a parameter to the replacement scan function.

Syntax

```
            void duckdb_replacement_scan_add_parameter(
  duckdb_replacement_scan_info info,
  duckdb_value parameter
);
```

Parameters

- `info`: The info object
- `parameter`: The parameter to add.

`duckdb_replacement_scan_set_error` Report that an error has occurred while executing the replacement scan.

Syntax

```
            void duckdb_replacement_scan_set_error(
  duckdb_replacement_scan_info info,
  const char *error
);
```

Parameters

- `info`: The info object
- `error`: The error message

Complete API

This page contains the reference for DuckDB's C API.

> The reference contains several deprecation notices. These concern methods whose long-term availability is not guaranteed as they may be removed in the future. That said, DuckDB's developers plan to carry out deprecations slowly as several of the deprecated methods do not yet have a fully functional alternative. Therefore, they will not be removed before the alternative is available, and even then, there will be a grace period of a few minor versions before removing them. The reason that the methods are already deprecated in v1.0 is to denote that they are not part of the v1.0 stable API, which contains methods that are available long-term.

API Reference Overview

Open Connect

```
            duckdb_instance_cache duckdb_create_instance_cache();
duckdb_state duckdb_get_or_create_from_cache(duckdb_instance_cache instance_cache, const char *path,
duckdb_database *out_database, duckdb_config config, char **out_error);
void duckdb_destroy_instance_cache(duckdb_instance_cache *instance_cache);
duckdb_state duckdb_open(const char *path, duckdb_database *out_database);
duckdb_state duckdb_open_ext(const char *path, duckdb_database *out_database, duckdb_config config, char
**out_error);
void duckdb_close(duckdb_database *database);
duckdb_state duckdb_connect(duckdb_database database, duckdb_connection *out_connection);
void duckdb_interrupt(duckdb_connection connection);
duckdb_query_progress_type duckdb_query_progress(duckdb_connection connection);
void duckdb_disconnect(duckdb_connection *connection);
void duckdb_connection_get_client_context(duckdb_connection connection, duckdb_client_context *out_
context);
void duckdb_connection_get_arrow_options(duckdb_connection connection, duckdb_arrow_options *out_arrow_
options);
idx_t duckdb_client_context_get_connection_id(duckdb_client_context context);
void duckdb_destroy_client_context(duckdb_client_context *context);
void duckdb_destroy_arrow_options(duckdb_arrow_options *arrow_options);
const char *duckdb_library_version();
duckdb_value duckdb_get_table_names(duckdb_connection connection, const char *query, bool qualified);
```

Configuration

```
            duckdb_state duckdb_create_config(duckdb_config *out_config);
size_t duckdb_config_count();
duckdb_state duckdb_get_config_flag(size_t index, const char **out_name, const char **out_description);
duckdb_state duckdb_set_config(duckdb_config config, const char *name, const char *option);
void duckdb_destroy_config(duckdb_config *config);
```

Error Data

```
            duckdb_error_data duckdb_create_error_data(duckdb_error_type type, const char *message);
void duckdb_destroy_error_data(duckdb_error_data *error_data);
duckdb_error_type duckdb_error_data_error_type(duckdb_error_data error_data);
```

```
const char *duckdb_error_data_message(duckdb_error_data error_data);
bool duckdb_error_data_has_error(duckdb_error_data error_data);
```

Query Execution

```
duckdb_state duckdb_query(duckdb_connection connection, const char *query, duckdb_result
*out_result);
void duckdb_destroy_result(duckdb_result *result);
const char *duckdb_column_name(duckdb_result *result, idx_t col);
duckdb_type duckdb_column_type(duckdb_result *result, idx_t col);
duckdb_statement_type duckdb_result_statement_type(duckdb_result result);
duckdb_logical_type duckdb_column_logical_type(duckdb_result *result, idx_t col);
duckdb_arrow_options duckdb_result_get_arrow_options(duckdb_result *result);
idx_t duckdb_column_count(duckdb_result *result);
idx_t duckdb_row_count(duckdb_result *result);
idx_t duckdb_rows_changed(duckdb_result *result);
void *duckdb_column_data(duckdb_result *result, idx_t col);
bool *duckdb_nullmask_data(duckdb_result *result, idx_t col);
const char *duckdb_result_error(duckdb_result *result);
duckdb_error_type duckdb_result_error_type(duckdb_result *result);
```

Result Functions

```
duckdb_data_chunk duckdb_result_get_chunk(duckdb_result result, idx_t chunk_index);
bool duckdb_result_is_streaming(duckdb_result result);
idx_t duckdb_result_chunk_count(duckdb_result result);
duckdb_result_type duckdb_result_return_type(duckdb_result result);
```

Safe Fetch Functions

```
bool duckdb_value_boolean(duckdb_result *result, idx_t col, idx_t row);
int8_t duckdb_value_int8(duckdb_result *result, idx_t col, idx_t row);
int16_t duckdb_value_int16(duckdb_result *result, idx_t col, idx_t row);
int32_t duckdb_value_int32(duckdb_result *result, idx_t col, idx_t row);
int64_t duckdb_value_int64(duckdb_result *result, idx_t col, idx_t row);
duckdb_hugeint duckdb_value_hugeint(duckdb_result *result, idx_t col, idx_t row);
duckdb_uhugeint duckdb_value_uhugeint(duckdb_result *result, idx_t col, idx_t row);
duckdb_decimal duckdb_value_decimal(duckdb_result *result, idx_t col, idx_t row);
uint8_t duckdb_value_uint8(duckdb_result *result, idx_t col, idx_t row);
uint16_t duckdb_value_uint16(duckdb_result *result, idx_t col, idx_t row);
uint32_t duckdb_value_uint32(duckdb_result *result, idx_t col, idx_t row);
uint64_t duckdb_value_uint64(duckdb_result *result, idx_t col, idx_t row);
float duckdb_value_float(duckdb_result *result, idx_t col, idx_t row);
double duckdb_value_double(duckdb_result *result, idx_t col, idx_t row);
duckdb_date duckdb_value_date(duckdb_result *result, idx_t col, idx_t row);
duckdb_time duckdb_value_time(duckdb_result *result, idx_t col, idx_t row);
duckdb_timestamp duckdb_value_timestamp(duckdb_result *result, idx_t col, idx_t row);
duckdb_interval duckdb_value_interval(duckdb_result *result, idx_t col, idx_t row);
char *duckdb_value_varchar(duckdb_result *result, idx_t col, idx_t row);
duckdb_string duckdb_value_string(duckdb_result *result, idx_t col, idx_t row);
char *duckdb_value_varchar_internal(duckdb_result *result, idx_t col, idx_t row);
duckdb_string duckdb_value_string_internal(duckdb_result *result, idx_t col, idx_t row);
duckdb_blob duckdb_value_blob(duckdb_result *result, idx_t col, idx_t row);
bool duckdb_value_is_null(duckdb_result *result, idx_t col, idx_t row);
```

Helpers

```
            void *duckdb_malloc(size_t size);
void duckdb_free(void *ptr);
idx_t duckdb_vector_size();
bool duckdb_string_is_inlined(duckdb_string_t string);
uint32_t duckdb_string_t_length(duckdb_string_t string);
const char *duckdb_string_t_data(duckdb_string_t *string);
```

Date Time Timestamp Helpers

```
            duckdb_date_struct duckdb_from_date(duckdb_date date);
duckdb_date duckdb_to_date(duckdb_date_struct date);
bool duckdb_is_finite_date(duckdb_date date);
duckdb_time_struct duckdb_from_time(duckdb_time time);
duckdb_time_tz duckdb_create_time_tz(int64_t micros, int32_t offset);
duckdb_time_tz_struct duckdb_from_time_tz(duckdb_time_tz micros);
duckdb_time duckdb_to_time(duckdb_time_struct time);
duckdb_timestamp_struct duckdb_from_timestamp(duckdb_timestamp ts);
duckdb_timestamp duckdb_to_timestamp(duckdb_timestamp_struct ts);
bool duckdb_is_finite_timestamp(duckdb_timestamp ts);
bool duckdb_is_finite_timestamp_s(duckdb_timestamp_s ts);
bool duckdb_is_finite_timestamp_ms(duckdb_timestamp_ms ts);
bool duckdb_is_finite_timestamp_ns(duckdb_timestamp_ns ts);
```

Hugeint Helpers

```
            double duckdb_hugeint_to_double(duckdb_hugeint val);
duckdb_hugeint duckdb_double_to_hugeint(double val);
```

Unsigned Hugeint Helpers

```
            double duckdb_uhugeint_to_double(duckdb_uhugeint val);
duckdb_uhugeint duckdb_double_to_uhugeint(double val);
```

Decimal Helpers

```
            duckdb_decimal duckdb_double_to_decimal(double val, uint8_t width, uint8_t scale);
double duckdb_decimal_to_double(duckdb_decimal val);
```

Prepared Statements

```
            duckdb_state duckdb_prepare(duckdb_connection connection, const char *query, duckdb_
prepared_statement *out_prepared_statement);
void duckdb_destroy_prepare(duckdb_prepared_statement *prepared_statement);
const char *duckdb_prepare_error(duckdb_prepared_statement prepared_statement);
idx_t duckdb_nparams(duckdb_prepared_statement prepared_statement);
const char *duckdb_parameter_name(duckdb_prepared_statement prepared_statement, idx_t index);
duckdb_type duckdb_param_type(duckdb_prepared_statement prepared_statement, idx_t param_idx);
duckdb_logical_type duckdb_param_logical_type(duckdb_prepared_statement prepared_statement, idx_t param_
idx);
duckdb_state duckdb_clear_bindings(duckdb_prepared_statement prepared_statement);
duckdb_statement_type duckdb_prepared_statement_type(duckdb_prepared_statement statement);
idx_t duckdb_prepared_statement_column_count(duckdb_prepared_statement prepared_statement);
```

```
const char *duckdb_prepared_statement_column_name(duckdb_prepared_statement prepared_statement, idx_t
col_idx);
duckdb_logical_type duckdb_prepared_statement_column_logical_type(duckdb_prepared_statement prepared_
statement, idx_t col_idx);
duckdb_type duckdb_prepared_statement_column_type(duckdb_prepared_statement prepared_statement, idx_t
col_idx);
```

Bind Values to Prepared Statements

```
            duckdb_state duckdb_bind_value(duckdb_prepared_statement prepared_statement, idx_t param_
idx, duckdb_value val);
duckdb_state duckdb_bind_parameter_index(duckdb_prepared_statement prepared_statement, idx_t *param_idx_
out, const char *name);
duckdb_state duckdb_bind_boolean(duckdb_prepared_statement prepared_statement, idx_t param_idx, bool
val);
duckdb_state duckdb_bind_int8(duckdb_prepared_statement prepared_statement, idx_t param_idx, int8_t
val);
duckdb_state duckdb_bind_int16(duckdb_prepared_statement prepared_statement, idx_t param_idx, int16_t
val);
duckdb_state duckdb_bind_int32(duckdb_prepared_statement prepared_statement, idx_t param_idx, int32_t
val);
duckdb_state duckdb_bind_int64(duckdb_prepared_statement prepared_statement, idx_t param_idx, int64_t
val);
duckdb_state duckdb_bind_hugeint(duckdb_prepared_statement prepared_statement, idx_t param_idx, duckdb_
hugeint val);
duckdb_state duckdb_bind_uhugeint(duckdb_prepared_statement prepared_statement, idx_t param_idx, duckdb_
uhugeint val);
duckdb_state duckdb_bind_decimal(duckdb_prepared_statement prepared_statement, idx_t param_idx, duckdb_
decimal val);
duckdb_state duckdb_bind_uint8(duckdb_prepared_statement prepared_statement, idx_t param_idx, uint8_t
val);
duckdb_state duckdb_bind_uint16(duckdb_prepared_statement prepared_statement, idx_t param_idx, uint16_t
val);
duckdb_state duckdb_bind_uint32(duckdb_prepared_statement prepared_statement, idx_t param_idx, uint32_t
val);
duckdb_state duckdb_bind_uint64(duckdb_prepared_statement prepared_statement, idx_t param_idx, uint64_t
val);
duckdb_state duckdb_bind_float(duckdb_prepared_statement prepared_statement, idx_t param_idx, float
val);
duckdb_state duckdb_bind_double(duckdb_prepared_statement prepared_statement, idx_t param_idx, double
val);
duckdb_state duckdb_bind_date(duckdb_prepared_statement prepared_statement, idx_t param_idx, duckdb_date
val);
duckdb_state duckdb_bind_time(duckdb_prepared_statement prepared_statement, idx_t param_idx, duckdb_time
val);
duckdb_state duckdb_bind_timestamp(duckdb_prepared_statement prepared_statement, idx_t param_idx,
duckdb_timestamp val);
duckdb_state duckdb_bind_timestamp_tz(duckdb_prepared_statement prepared_statement, idx_t param_idx,
duckdb_timestamp val);
duckdb_state duckdb_bind_interval(duckdb_prepared_statement prepared_statement, idx_t param_idx, duckdb_
interval val);
duckdb_state duckdb_bind_varchar(duckdb_prepared_statement prepared_statement, idx_t param_idx, const
char *val);
duckdb_state duckdb_bind_varchar_length(duckdb_prepared_statement prepared_statement, idx_t param_idx,
const char *val, idx_t length);
duckdb_state duckdb_bind_blob(duckdb_prepared_statement prepared_statement, idx_t param_idx, const void
*data, idx_t length);
duckdb_state duckdb_bind_null(duckdb_prepared_statement prepared_statement, idx_t param_idx);
```

Execute Prepared Statements

```
            duckdb_state duckdb_execute_prepared(duckdb_prepared_statement prepared_statement, duckdb_
result *out_result);
duckdb_state duckdb_execute_prepared_streaming(duckdb_prepared_statement prepared_statement, duckdb_
result *out_result);
```

Extract Statements

```
            idx_t duckdb_extract_statements(duckdb_connection connection, const char *query, duckdb_
extracted_statements *out_extracted_statements);
duckdb_state duckdb_prepare_extracted_statement(duckdb_connection connection, duckdb_extracted_
statements extracted_statements, idx_t index, duckdb_prepared_statement *out_prepared_statement);
const char *duckdb_extract_statements_error(duckdb_extracted_statements extracted_statements);
void duckdb_destroy_extracted(duckdb_extracted_statements *extracted_statements);
```

Pending Result Interface

```
            duckdb_state duckdb_pending_prepared(duckdb_prepared_statement prepared_statement, duckdb_
pending_result *out_result);
duckdb_state duckdb_pending_prepared_streaming(duckdb_prepared_statement prepared_statement, duckdb_
pending_result *out_result);
void duckdb_destroy_pending(duckdb_pending_result *pending_result);
const char *duckdb_pending_error(duckdb_pending_result pending_result);
duckdb_pending_state duckdb_pending_execute_task(duckdb_pending_result pending_result);
duckdb_pending_state duckdb_pending_execute_check_state(duckdb_pending_result pending_result);
duckdb_state duckdb_execute_pending(duckdb_pending_result pending_result, duckdb_result *out_result);
bool duckdb_pending_execution_is_finished(duckdb_pending_state pending_state);
```

Value Interface

```
            void duckdb_destroy_value(duckdb_value *value);
duckdb_value duckdb_create_varchar(const char *text);
duckdb_value duckdb_create_varchar_length(const char *text, idx_t length);
duckdb_value duckdb_create_bool(bool input);
duckdb_value duckdb_create_int8(int8_t input);
duckdb_value duckdb_create_uint8(uint8_t input);
duckdb_value duckdb_create_int16(int16_t input);
duckdb_value duckdb_create_uint16(uint16_t input);
duckdb_value duckdb_create_int32(int32_t input);
duckdb_value duckdb_create_uint32(uint32_t input);
duckdb_value duckdb_create_uint64(uint64_t input);
duckdb_value duckdb_create_int64(int64_t val);
duckdb_value duckdb_create_hugeint(duckdb_hugeint input);
duckdb_value duckdb_create_uhugeint(duckdb_uhugeint input);
duckdb_value duckdb_create_bignum(duckdb_bignum input);
duckdb_value duckdb_create_decimal(duckdb_decimal input);
duckdb_value duckdb_create_float(float input);
duckdb_value duckdb_create_double(double input);
duckdb_value duckdb_create_date(duckdb_date input);
duckdb_value duckdb_create_time(duckdb_time input);
duckdb_value duckdb_create_time_ns(duckdb_time_ns input);
duckdb_value duckdb_create_time_tz_value(duckdb_time_tz value);
duckdb_value duckdb_create_timestamp(duckdb_timestamp input);
duckdb_value duckdb_create_timestamp_tz(duckdb_timestamp input);

vector output);
duckdb_state duckdb_register_cast_function(duckdb_connection con, duckdb_cast_function cast_function);
void duckdb_destroy_cast_function(duckdb_cast_function *cast_function);
```

Expression Interface

```
            void duckdb_destroy_expression(duckdb_expression *expr);
duckdb_logical_type duckdb_expression_return_type(duckdb_expression expr);
bool duckdb_expression_is_foldable(duckdb_expression expr);
duckdb_error_data duckdb_expression_fold(duckdb_client_context context, duckdb_expression expr, duckdb_
value *out_value);
```

`duckdb_create_instance_cache` Creates a new database instance cache. The instance cache is necessary if a client/program (re)opens multiple databases to the same file within the same process. Must be destroyed with 'duckdb_destroy_instance_cache'.

Return Value The database instance cache.

Syntax

```
            duckdb_instance_cache duckdb_create_instance_cache(

);
```

`duckdb_get_or_create_from_cache` Creates a new database instance in the instance cache, or retrieves an existing database instance. Must be closed with 'duckdb_close'.

Syntax

```
            duckdb_state duckdb_get_or_create_from_cache(
  duckdb_instance_cache instance_cache,
  const char *path,
  duckdb_database *out_database,
  duckdb_config config,
  char **out_error
);
```

Parameters

- `instance_cache`: The instance cache in which to create the database, or from which to take the database.
- `path`: Path to the database file on disk. Both `nullptr` and `:memory:` open or retrieve an in-memory database.
- `out_database`: The resulting cached database.
- `config`: (Optional) configuration used to create the database.
- `out_error`: If set and the function returns `DuckDBError`, this contains the error message. Note that the error message must be freed using `duckdb_free`.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

duckdb_destroy_instance_cache Destroys an existing database instance cache and de-allocates its memory.

Syntax

```
            void duckdb_destroy_instance_cache(
  duckdb_instance_cache *instance_cache
);
```

Parameters

- `instance_cache`: The instance cache to destroy.

duckdb_open Creates a new database or opens an existing database file stored at the given path. If no path is given a new in-memory database is created instead. The database must be closed with 'duckdb_close'.

Syntax

```
            duckdb_state duckdb_open(
  const char *path,
  duckdb_database *out_database
);
```

Parameters

- `path`: Path to the database file on disk. Both `nullptr` and `:memory:` open an in-memory database.
- `out_database`: The result database object.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

duckdb_open_ext Extended version of duckdb_open. Creates a new database or opens an existing database file stored at the given path. The database must be closed with 'duckdb_close'.

Syntax

```
            duckdb_state duckdb_open_ext(
  const char *path,
  duckdb_database *out_database,
  duckdb_config config,
  char **out_error
);
```

Parameters

- `path`: Path to the database file on disk. Both `nullptr` and `:memory:` open an in-memory database.
- `out_database`: The result database object.
- `config`: (Optional) configuration used to start up the database.
- `out_error`: If set and the function returns `DuckDBError`, this contains the error message. Note that the error message must be freed using `duckdb_free`.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_close` Closes the specified database and de-allocates all memory allocated for that database. This should be called after you are done with any database allocated through `duckdb_open` or `duckdb_open_ext`. Note that failing to call `duckdb_close` (in case of e.g., a program crash) will not cause data corruption. Still, it is recommended to always correctly close a database object after you are done with it.

Syntax

```
            void duckdb_close(
  duckdb_database *database
);
```

Parameters

- `database`: The database object to shut down.

`duckdb_connect` Opens a connection to a database. Connections are required to query the database, and store transactional state associated with the connection. The instantiated connection should be closed using 'duckdb_disconnect'.

Syntax

```
            duckdb_state duckdb_connect(
  duckdb_database database,
  duckdb_connection *out_connection
);
```

Parameters

- `database`: The database file to connect to.
- `out_connection`: The result connection object.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_interrupt` Interrupt running query

Syntax

```
            void duckdb_interrupt(
  duckdb_connection connection
);
```

Parameters

- `connection`: The connection to interrupt

`duckdb_query_progress` Get progress of the running query

Syntax

```
            duckdb_query_progress_type duckdb_query_progress(
  duckdb_connection connection
);
```

Parameters

- `connection`: The working connection

Return Value -1 if no progress or a percentage of the progress

`duckdb_disconnect`

Closes the specified connection and de-allocates all memory allocated for that connection.

Syntax

```
            void duckdb_disconnect(
  duckdb_connection *connection
);
```

Parameters

- `connection`: The connection to close.

`duckdb_connection_get_client_context`

Retrieves the client context of the connection.

Syntax

```
            void duckdb_connection_get_client_context(
  duckdb_connection connection,
  duckdb_client_context *out_context
);
```

Parameters

- `connection`: The connection.
- `out_context`: The client context of the connection. Must be destroyed with `duckdb_destroy_client_context`.

`duckdb_connection_get_arrow_options`

Retrieves the arrow options of the connection.

Syntax

```
            void duckdb_connection_get_arrow_options(
  duckdb_connection connection,
  duckdb_arrow_options *out_arrow_options
);
```

Parameters

- `connection`: The connection.

`duckdb_client_context_get_connection_id`

Returns the connection id of the client context.

Syntax

```
            idx_t duckdb_client_context_get_connection_id(
  duckdb_client_context context
);
```

Parameters

- `context`: The client context.

Return Value The connection id of the client context.

`duckdb_destroy_client_context`

Destroys the client context and deallocates its memory.

Syntax

```
            void duckdb_destroy_client_context(
  duckdb_client_context *context
);
```

Parameters

- `context`: The client context to destroy.

`duckdb_destroy_arrow_options`

Destroys the arrow options and deallocates its memory.

Syntax

```
            void duckdb_destroy_arrow_options(
  duckdb_arrow_options *arrow_options
);
```

Parameters

- `arrow_options`: The arrow options to destroy.

`duckdb_library_version`

Returns the version of the linked DuckDB, with a version postfix for dev versions

Usually used for developing C extensions that must return this for a compatibility check.

Syntax

```
            const char *duckdb_library_version(

);
```

`duckdb_get_table_names`

Get the list of (fully qualified) table names of the query.

Syntax

```
            duckdb_value duckdb_get_table_names(
  duckdb_connection connection,
  const char *query,
  bool qualified
);
```

Parameters

- `connection`: The connection for which to get the table names.
- `query`: The query for which to get the table names.
- `qualified`: Returns fully qualified table names (catalog.schema.table), if set to true, else only the (not escaped) table names.

Return Value A duckdb_value of type VARCHAR[] containing the (fully qualified) table names of the query. Must be destroyed with duckdb_destroy_value.

`duckdb_create_config` Initializes an empty configuration object that can be used to provide start-up options for the DuckDB instance through `duckdb_open_ext`. The duckdb_config must be destroyed using 'duckdb_destroy_config'

This will always succeed unless there is a malloc failure.

Note that `duckdb_destroy_config` should always be called on the resulting config, even if the function returns `DuckDBError`.

Syntax

```
            duckdb_state duckdb_create_config(
  duckdb_config *out_config
);
```

Parameters

- `out_config`: The result configuration object.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_config_count` This returns the total amount of configuration options available for usage with `duckdb_get_config_flag`.

This should not be called in a loop as it internally loops over all the options.

Return Value The amount of config options available.

Syntax

```
            size_t duckdb_config_count(

);
```

`duckdb_get_config_flag` Obtains a human-readable name and description of a specific configuration option. This can be used to e.g. display configuration options. This will succeed unless `index` is out of range (i.e., `>= duckdb_config_count`).

The result name or description MUST NOT be freed.

Syntax

```
            duckdb_state duckdb_get_config_flag(
  size_t index,
  const char **out_name,
  const char **out_description
);
```

Parameters

- `index`: The index of the configuration option (between 0 and `duckdb_config_count`)
- `out_name`: A name of the configuration flag.
- `out_description`: A description of the configuration flag.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_set_config` Sets the specified option for the specified configuration. The configuration option is indicated by name. To obtain a list of config options, see `duckdb_get_config_flag`.

In the source code, configuration options are defined in `config.cpp`.

This can fail if either the name is invalid, or if the value provided for the option is invalid.

Syntax

```
            duckdb_state duckdb_set_config(
  duckdb_config config,
  const char *name,
  const char *option
);
```

Parameters

- `config`: The configuration object to set the option on.
- `name`: The name of the configuration flag to set.
- `option`: The value to set the configuration flag to.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_destroy_config` Destroys the specified configuration object and de-allocates all memory allocated for the object.

Syntax

```
            void duckdb_destroy_config(
  duckdb_config *config
);
```

Parameters

- `config`: The configuration object to destroy.

`duckdb_create_error_data` Creates duckdb_error_data. Must be destroyed with `duckdb_destroy_error_data`.

Syntax

```
            duckdb_error_data duckdb_create_error_data(
  duckdb_error_type type,
  const char *message
);
```

Parameters

- `type`: The error type.
- `message`: The error message.

Return Value The error data.

`duckdb_destroy_error_data`

Destroys the error data and deallocates its memory.

Syntax

```
            void duckdb_destroy_error_data(
  duckdb_error_data *error_data
);
```

Parameters

- `error_data`: The error data to destroy.

`duckdb_error_data_error_type`

Returns the duckdb_error_type of the error data.

Syntax

```
            duckdb_error_type duckdb_error_data_error_type(
  duckdb_error_data error_data
);
```

Parameters

- `error_data`: The error data.

Return Value The error type.

`duckdb_error_data_message`

Returns the error message of the error data. Must not be freed.

Syntax

```
            const char *duckdb_error_data_message(
  duckdb_error_data error_data
);
```

Parameters

- `error_data`: The error data.

Return Value The error message.

`duckdb_error_data_has_error`

Returns whether the error data contains an error or not.

Syntax

```
            bool duckdb_error_data_has_error(
  duckdb_error_data error_data
);
```

Parameters

- `error_data`: The error data.

Return Value True, if the error data contains an exception, else false.

`duckdb_query` Executes a SQL query within a connection and stores the full (materialized) result in the out_result pointer. If the query fails to execute, DuckDBError is returned and the error message can be retrieved by calling `duckdb_result_error`.

Note that after running `duckdb_query`, `duckdb_destroy_result` must be called on the result object even if the query fails, otherwise the error stored within the result will not be freed correctly.

Syntax

```
            duckdb_state duckdb_query(
  duckdb_connection connection,
  const char *query,
  duckdb_result *out_result
);
```

Parameters

- `connection`: The connection to perform the query in.
- `query`: The SQL query to run.
- `out_result`: The query result.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_destroy_result` Closes the result and de-allocates all memory allocated for that result.

Syntax

```
            void duckdb_destroy_result(
  duckdb_result *result
);
```

Parameters

- `result`: The result to destroy.

`duckdb_column_name` Returns the column name of the specified column. The result should not need to be freed; the column names will automatically be destroyed when the result is destroyed.

Returns `NULL` if the column is out of range.

Syntax

```
            const char *duckdb_column_name(
  duckdb_result *result,
  idx_t col
);
```

Parameters

- `result`: The result object to fetch the column name from.
- `col`: The column index.

Return Value The column name of the specified column.

`duckdb_column_type` Returns the column type of the specified column.

Returns DUCKDB_TYPE_INVALID if the column is out of range.

Syntax

```
            duckdb_type duckdb_column_type(
  duckdb_result *result,
  idx_t col
);
```

Parameters

- `result`: The result object to fetch the column type from.
- `col`: The column index.

Return Value The column type of the specified column.

`duckdb_result_statement_type` Returns the statement type of the statement that was executed

Syntax

```
            duckdb_statement_type duckdb_result_statement_type(
  duckdb_result result
);
```

Parameters

- `result`: The result object to fetch the statement type from.

Return Value duckdb_statement_type value or DUCKDB_STATEMENT_TYPE_INVALID

`duckdb_column_logical_type` Returns the logical column type of the specified column.

The return type of this call should be destroyed with `duckdb_destroy_logical_type`.

Returns `NULL` if the column is out of range.

Syntax

```
            duckdb_logical_type duckdb_column_logical_type(
  duckdb_result *result,
  idx_t col
);
```

Parameters

- `result`: The result object to fetch the column type from.
- `col`: The column index.

Return Value The logical column type of the specified column.

`duckdb_result_get_arrow_options` Returns the arrow options associated with the given result. These options are definitions of how the arrow arrays/schema should be produced.

Syntax

```
            duckdb_arrow_options duckdb_result_get_arrow_options(
  duckdb_result *result
);
```

Parameters

- `result`: The result object to fetch arrow options from.

Return Value The arrow options associated with the given result. This must be destroyed with `duckdb_destroy_arrow_options`.

`duckdb_column_count` Returns the number of columns present in a the result object.

Syntax

```
            idx_t duckdb_column_count(
  duckdb_result *result
);
```

Parameters

- `result`: The result object.

Return Value The number of columns present in the result object.

`duckdb_row_count`

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Returns the number of rows present in the result object.

Syntax

```
            idx_t duckdb_row_count(
  duckdb_result *result
);
```

Parameters

- `result`: The result object.

Return Value The number of rows present in the result object.

`duckdb_rows_changed` Returns the number of rows changed by the query stored in the result. This is relevant only for INSERT/UPDATE/DELETE queries. For other queries the rows_changed will be 0.

Syntax

```
            idx_t duckdb_rows_changed(
  duckdb_result *result
);
```

Parameters

- `result`: The result object.

Return Value The number of rows changed.

`duckdb_column_data`

> **Deprecated.** This method has been deprecated. Prefer using `duckdb_result_get_chunk` instead.

Returns the data of a specific column of a result in columnar format.

The function returns a dense array which contains the result data. The exact type stored in the array depends on the corresponding duckdb_type (as provided by `duckdb_column_type`). For the exact type by which the data should be accessed, see the comments in the types section or the DUCKDB_TYPE enum.

For example, for a column of type DUCKDB_TYPE_INTEGER, rows can be accessed in the following manner:

```
int32_t *data = (int32_t *) duckdb_column_data(&result, 0);
printf("Data for row %d: %d\n", row, data[row]);
```

Syntax

```
            void *duckdb_column_data(
  duckdb_result *result,
  idx_t col
);
```

Parameters

- `result`: The result object to fetch the column data from.
- `col`: The column index.

Return Value The column data of the specified column.

duckdb_nullmask_data

> **Deprecated.** This method has been deprecated. Prefer using `duckdb_result_get_chunk` instead.

Returns the nullmask of a specific column of a result in columnar format. The nullmask indicates for every row whether or not the corresponding row is `NULL`. If a row is `NULL`, the values present in the array provided by `duckdb_column_data` are undefined.

```
int32_t *data = (int32_t *) duckdb_column_data(&result, 0);
bool *nullmask = duckdb_nullmask_data(&result, 0);
if (nullmask[row]) {
    printf("Data for row %d: NULL\n", row);
} else {
    printf("Data for row %d: %d\n", row, data[row]);
}
```

Syntax

```
            bool *duckdb_nullmask_data(
  duckdb_result *result,
  idx_t col
);
```

Parameters

- `result`: The result object to fetch the nullmask from.
- `col`: The column index.

Return Value The nullmask of the specified column.

duckdb_result_error Returns the error message contained within the result. The error is only set if `duckdb_query` returns `DuckDBError`.

The result of this function must not be freed. It will be cleaned up when `duckdb_destroy_result` is called.

Syntax

```
            const char *duckdb_result_error(
  duckdb_result *result
);
```

Parameters

- `result`: The result object to fetch the error from.

Return Value The error of the result.

duckdb_result_error_type Returns the result error type contained within the result. The error is only set if `duckdb_query` returns `DuckDBError`.

Syntax

```
            duckdb_error_type duckdb_result_error_type(
  duckdb_result *result
);
```

Parameters

- `result`: The result object to fetch the error from.

Return Value The error type of the result.

`duckdb_result_get_chunk`

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Fetches a data chunk from the duckdb_result. This function should be called repeatedly until the result is exhausted.

The result must be destroyed with `duckdb_destroy_data_chunk`.

This function supersedes all `duckdb_value` functions, as well as the `duckdb_column_data` and `duckdb_nullmask_data` functions. It results in significantly better performance, and should be preferred in newer code-bases.

If this function is used, none of the other result functions can be used and vice versa (i.e., this function cannot be mixed with the legacy result functions).

Use `duckdb_result_chunk_count` to figure out how many chunks there are in the result.

Syntax

```
            duckdb_data_chunk duckdb_result_get_chunk(
  duckdb_result result,
  idx_t chunk_index
);
```

Parameters

- `result`: The result object to fetch the data chunk from.
- `chunk_index`: The chunk index to fetch from.

Return Value The resulting data chunk. Returns `NULL` if the chunk index is out of bounds.

`duckdb_result_is_streaming`

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Checks if the type of the internal result is StreamQueryResult.

Syntax

```
            bool duckdb_result_is_streaming(
  duckdb_result result
);
```

Parameters

- `result`: The result object to check.

Return Value Whether or not the result object is of the type StreamQueryResult

`duckdb_result_chunk_count`

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Returns the number of data chunks present in the result.

Syntax

```
            idx_t duckdb_result_chunk_count(
  duckdb_result result
);
```

Parameters

- `result`: The result object

Return Value Number of data chunks present in the result.

`duckdb_result_return_type` Returns the return_type of the given result, or DUCKDB_RETURN_TYPE_INVALID on error

Syntax

```
            duckdb_result_type duckdb_result_return_type(
  duckdb_result result
);
```

Parameters

- `result`: The result object

Return Value The return_type

`duckdb_value_boolean`

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Return Value The boolean value at the specified location, or false if the value cannot be converted.

Syntax

```
            bool duckdb_value_boolean(
  duckdb_result *result,
  idx_t col,
  idx_t row
);
```

`duckdb_value_int8`

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Return Value The int8_t value at the specified location, or 0 if the value cannot be converted.

Syntax

```
            int8_t duckdb_value_int8(
  duckdb_result *result,
  idx_t col,
  idx_t row
);
```

duckdb_value_int16

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Return Value The int16_t value at the specified location, or 0 if the value cannot be converted.

Syntax

```
            int16_t duckdb_value_int16(
  duckdb_result *result,
  idx_t col,
  idx_t row
);
```

duckdb_value_int32

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Return Value The int32_t value at the specified location, or 0 if the value cannot be converted.

Syntax

```
            int32_t duckdb_value_int32(
  duckdb_result *result,
  idx_t col,
  idx_t row
);
```

duckdb_value_int64

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Return Value The int64_t value at the specified location, or 0 if the value cannot be converted.

Syntax

```
            int64_t duckdb_value_int64(
  duckdb_result *result,
  idx_t col,
  idx_t row
);
```

duckdb_value_hugeint

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Return Value The duckdb_hugeint value at the specified location, or 0 if the value cannot be converted.

Syntax

```
           duckdb_hugeint duckdb_value_hugeint(
  duckdb_result *result,
  idx_t col,
  idx_t row
);
```

duckdb_value_uhugeint

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Return Value The duckdb_uhugeint value at the specified location, or 0 if the value cannot be converted.

Syntax

```
           duckdb_uhugeint duckdb_value_uhugeint(
  duckdb_result *result,
  idx_t col,
  idx_t row
);
```

duckdb_value_decimal

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Return Value The duckdb_decimal value at the specified location, or 0 if the value cannot be converted.

Syntax

```
           duckdb_decimal duckdb_value_decimal(
  duckdb_result *result,
  idx_t col,
  idx_t row
);
```

duckdb_value_uint8

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Return Value The uint8_t value at the specified location, or 0 if the value cannot be converted.

Syntax

```
           uint8_t duckdb_value_uint8(
  duckdb_result *result,
  idx_t col,
  idx_t row
);
```

duckdb_value_uint16

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Return Value The uint16_t value at the specified location, or 0 if the value cannot be converted.

Syntax

```
            uint16_t duckdb_value_uint16(
  duckdb_result *result,
  idx_t col,
  idx_t row
);
```

duckdb_value_uint32

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Return Value The uint32_t value at the specified location, or 0 if the value cannot be converted.

Syntax

```
            uint32_t duckdb_value_uint32(
  duckdb_result *result,
  idx_t col,
  idx_t row
);
```

duckdb_value_uint64

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Return Value The uint64_t value at the specified location, or 0 if the value cannot be converted.

Syntax

```
            uint64_t duckdb_value_uint64(
  duckdb_result *result,
  idx_t col,
  idx_t row
);
```

duckdb_value_float

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Return Value The float value at the specified location, or 0 if the value cannot be converted.

Syntax

```
            float duckdb_value_float(
  duckdb_result *result,
  idx_t col,
  idx_t row
);
```

duckdb_value_double

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Return Value The double value at the specified location, or 0 if the value cannot be converted.

Syntax

```
            double duckdb_value_double(
  duckdb_result *result,
  idx_t col,
  idx_t row
);
```

duckdb_value_date

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Return Value The duckdb_date value at the specified location, or 0 if the value cannot be converted.

Syntax

```
            duckdb_date duckdb_value_date(
  duckdb_result *result,
  idx_t col,
  idx_t row
);
```

duckdb_value_time

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Return Value The duckdb_time value at the specified location, or 0 if the value cannot be converted.

Syntax

```
            duckdb_time duckdb_value_time(
  duckdb_result *result,
  idx_t col,
  idx_t row
);
```

duckdb_value_timestamp

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Return Value The duckdb_timestamp value at the specified location, or 0 if the value cannot be converted.

Syntax

```
            duckdb_timestamp duckdb_value_timestamp(
  duckdb_result *result,
  idx_t col,
  idx_t row
);
```

duckdb_value_interval

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Return Value The duckdb_interval value at the specified location, or 0 if the value cannot be converted.

Syntax

```
           duckdb_interval duckdb_value_interval(
  duckdb_result *result,
  idx_t col,
  idx_t row
);
```

duckdb_value_varchar

> **Deprecated.** This method has been deprecated. Use duckdb_value_string instead. This function does not work correctly if the string contains null bytes.

Return Value The text value at the specified location as a null-terminated string, or nullptr if the value cannot be converted. The result must be freed with `duckdb_free`.

Syntax

```
           char *duckdb_value_varchar(
  duckdb_result *result,
  idx_t col,
  idx_t row
);
```

duckdb_value_string

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

No support for nested types, and for other complex types. The resulting field "string.data" must be freed with `duckdb_free`.

Return Value The string value at the specified location. Attempts to cast the result value to string.

Syntax

```
           duckdb_string duckdb_value_string(
  duckdb_result *result,
  idx_t col,
  idx_t row
);
```

duckdb_value_varchar_internal

> **Deprecated.** This method has been deprecated. Use duckdb_value_string_internal instead. This function does not work correctly if the string contains null bytes.

Return Value The char* value at the specified location. ONLY works on VARCHAR columns and does not auto-cast. If the column is NOT a VARCHAR column this function will return NULL.

The result must NOT be freed.

Syntax

```
           char *duckdb_value_varchar_internal(
  duckdb_result *result,
  idx_t col,
  idx_t row
);
```

`duckdb_value_string_internal`

> **Deprecated.** This method has been deprecated. Use duckdb_value_string_internal instead. This function does not work correctly if the string contains null bytes.

Return Value The char* value at the specified location. ONLY works on VARCHAR columns and does not auto-cast. If the column is NOT a VARCHAR column this function will return NULL.

The result must NOT be freed.

Syntax

```
            duckdb_string duckdb_value_string_internal(
  duckdb_result *result,
  idx_t col,
  idx_t row
);
```

`duckdb_value_blob`

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Return Value The duckdb_blob value at the specified location. Returns a blob with blob.data set to nullptr if the value cannot be converted. The resulting field "blob.data" must be freed with `duckdb_free`.

Syntax

```
            duckdb_blob duckdb_value_blob(
  duckdb_result *result,
  idx_t col,
  idx_t row
);
```

`duckdb_value_is_null`

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Return Value Returns true if the value at the specified index is NULL, and false otherwise.

Syntax

```
            bool duckdb_value_is_null(
  duckdb_result *result,
  idx_t col,
  idx_t row
);
```

`duckdb_malloc` Allocate `size` bytes of memory using the duckdb internal malloc function. Any memory allocated in this manner should be freed using `duckdb_free`.

Syntax

```
            void *duckdb_malloc(
  size_t size
);
```

Parameters

- `size`: The number of bytes to allocate.

Return Value A pointer to the allocated memory region.

`duckdb_free` Free a value returned from `duckdb_malloc`, `duckdb_value_varchar`, `duckdb_value_blob`, or `duckdb_value_string`.

Syntax

```
            void duckdb_free(
  void *ptr
);
```

Parameters

- `ptr`: The memory region to de-allocate.

`duckdb_vector_size` The internal vector size used by DuckDB. This is the amount of tuples that will fit into a data chunk created by `duckdb_create_data_chunk`.

Return Value The vector size.

Syntax

```
            idx_t duckdb_vector_size(

);
```

`duckdb_string_is_inlined` Whether or not the duckdb_string_t value is inlined. This means that the data of the string does not have a separate allocation.

Syntax

```
            bool duckdb_string_is_inlined(
  duckdb_string_t string
);
```

`duckdb_string_t_length` Get the string length of a string_t

Syntax

```
            uint32_t duckdb_string_t_length(
  duckdb_string_t string
);
```

Parameters

- `string`: The string to get the length of.

Return Value The length.

duckdb_string_t_data Get a pointer to the string data of a string_t

Syntax

```
            const char *duckdb_string_t_data(
  duckdb_string_t *string
);
```

Parameters

- `string`: The string to get the pointer to.

Return Value The pointer.

duckdb_from_date Decompose a `duckdb_date` object into year, month and date (stored as `duckdb_date_struct`).

Syntax

```
            duckdb_date_struct duckdb_from_date(
  duckdb_date date
);
```

Parameters

- `date`: The date object, as obtained from a `DUCKDB_TYPE_DATE` column.

Return Value The `duckdb_date_struct` with the decomposed elements.

duckdb_to_date Re-compose a `duckdb_date` from year, month and date (`duckdb_date_struct`).

Syntax

```
            duckdb_date duckdb_to_date(
  duckdb_date_struct date
);
```

Parameters

- `date`: The year, month and date stored in a `duckdb_date_struct`.

Return Value The `duckdb_date` element.

duckdb_is_finite_date Test a `duckdb_date` to see if it is a finite value.

Syntax

```
            bool duckdb_is_finite_date(
  duckdb_date date
);
```

Parameters

- `date`: The date object, as obtained from a `DUCKDB_TYPE_DATE` column.

Return Value True if the date is finite, false if it is ±infinity.

`duckdb_from_time` Decompose a `duckdb_time` object into hour, minute, second and microsecond (stored as `duckdb_time_struct`).

Syntax

```
            duckdb_time_struct duckdb_from_time(
  duckdb_time time
);
```

Parameters

- `time`: The time object, as obtained from a `DUCKDB_TYPE_TIME` column.

Return Value The `duckdb_time_struct` with the decomposed elements.

`duckdb_create_time_tz` Create a `duckdb_time_tz` object from micros and a timezone offset.

Syntax

```
            duckdb_time_tz duckdb_create_time_tz(
  int64_t micros,
  int32_t offset
);
```

Parameters

- `micros`: The microsecond component of the time.
- `offset`: The timezone offset component of the time.

Return Value The `duckdb_time_tz` element.

`duckdb_from_time_tz` Decompose a TIME_TZ objects into micros and a timezone offset.

Use `duckdb_from_time` to further decompose the micros into hour, minute, second and microsecond.

Syntax

```
            duckdb_time_tz_struct duckdb_from_time_tz(
  duckdb_time_tz micros
);
```

Parameters

- `micros`: The time object, as obtained from a `DUCKDB_TYPE_TIME_TZ` column.

`duckdb_to_time` Re-compose a `duckdb_time` from hour, minute, second and microsecond (`duckdb_time_struct`).

Syntax

```
            duckdb_time duckdb_to_time(
  duckdb_time_struct time
);
```

Parameters

- `time`: The hour, minute, second and microsecond in a `duckdb_time_struct`.

Return Value The `duckdb_time` element.

`duckdb_from_timestamp` Decompose a `duckdb_timestamp` object into a `duckdb_timestamp_struct`.

Syntax

```
            duckdb_timestamp_struct duckdb_from_timestamp(
  duckdb_timestamp ts
);
```

Parameters

- `ts`: The ts object, as obtained from a `DUCKDB_TYPE_TIMESTAMP` column.

Return Value The `duckdb_timestamp_struct` with the decomposed elements.

`duckdb_to_timestamp` Re-compose a `duckdb_timestamp` from a duckdb_timestamp_struct.

Syntax

```
            duckdb_timestamp duckdb_to_timestamp(
  duckdb_timestamp_struct ts
);
```

Parameters

- `ts`: The de-composed elements in a `duckdb_timestamp_struct`.

Return Value The `duckdb_timestamp` element.

`duckdb_is_finite_timestamp` Test a `duckdb_timestamp` to see if it is a finite value.

Syntax

```
            bool duckdb_is_finite_timestamp(
  duckdb_timestamp ts
);
```

Parameters

- `ts`: The duckdb_timestamp object, as obtained from a `DUCKDB_TYPE_TIMESTAMP` column.

Return Value True if the timestamp is finite, false if it is ±infinity.

`duckdb_is_finite_timestamp_s` Test a `duckdb_timestamp_s` to see if it is a finite value.

Syntax

```
            bool duckdb_is_finite_timestamp_s(
  duckdb_timestamp_s ts
);
```

Parameters

- `ts`: The duckdb_timestamp_s object, as obtained from a `DUCKDB_TYPE_TIMESTAMP_S` column.

Return Value True if the timestamp is finite, false if it is ±infinity.

`duckdb_is_finite_timestamp_ms` Test a `duckdb_timestamp_ms` to see if it is a finite value.

Syntax

```
            bool duckdb_is_finite_timestamp_ms(
  duckdb_timestamp_ms ts
);
```

Parameters

- `ts`: The duckdb_timestamp_ms object, as obtained from a `DUCKDB_TYPE_TIMESTAMP_MS` column.

Return Value True if the timestamp is finite, false if it is ±infinity.

`duckdb_is_finite_timestamp_ns` Test a `duckdb_timestamp_ns` to see if it is a finite value.

Syntax

```
            bool duckdb_is_finite_timestamp_ns(
  duckdb_timestamp_ns ts
);
```

Parameters

- `ts`: The duckdb_timestamp_ns object, as obtained from a `DUCKDB_TYPE_TIMESTAMP_NS` column.

Return Value True if the timestamp is finite, false if it is ±infinity.

`duckdb_hugeint_to_double` Converts a duckdb_hugeint object (as obtained from a `DUCKDB_TYPE_HUGEINT` column) into a double.

Syntax

```
            double duckdb_hugeint_to_double(
  duckdb_hugeint val
);
```

Parameters

- `val`: The hugeint value.

Return Value The converted `double` element.

`duckdb_double_to_hugeint` Converts a double value to a duckdb_hugeint object.

If the conversion fails because the double value is too big the result will be 0.

Syntax

```
            duckdb_hugeint duckdb_double_to_hugeint(
  double val
);
```

Parameters

- `val`: The double value.

Return Value The converted `duckdb_hugeint` element.

`duckdb_uhugeint_to_double` Converts a duckdb_uhugeint object (as obtained from a `DUCKDB_TYPE_UHUGEINT` column) into a double.

Syntax

```
            double duckdb_uhugeint_to_double(
  duckdb_uhugeint val
);
```

Parameters

- `val`: The uhugeint value.

Return Value The converted `double` element.

`duckdb_double_to_uhugeint` Converts a double value to a duckdb_uhugeint object.

If the conversion fails because the double value is too big the result will be 0.

Syntax

```
            duckdb_uhugeint duckdb_double_to_uhugeint(
  double val
);
```

Parameters

- `val`: The double value.

Return Value The converted `duckdb_uhugeint` element.

`duckdb_double_to_decimal` Converts a double value to a duckdb_decimal object.

If the conversion fails because the double value is too big, or the width/scale are invalid the result will be 0.

Syntax

```
            duckdb_decimal duckdb_double_to_decimal(
  double val,
  uint8_t width,
  uint8_t scale
);
```

Parameters

- `val`: The double value.

Return Value The converted `duckdb_decimal` element.

`duckdb_decimal_to_double` Converts a duckdb_decimal object (as obtained from a `DUCKDB_TYPE_DECIMAL` column) into a double.

Syntax

```
            double duckdb_decimal_to_double(
  duckdb_decimal val
);
```

Parameters

- `val`: The decimal value.

Return Value The converted `double` element.

`duckdb_prepare` Create a prepared statement object from a query.

Note that after calling `duckdb_prepare`, the prepared statement should always be destroyed using `duckdb_destroy_prepare`, even if the prepare fails.

If the prepare fails, `duckdb_prepare_error` can be called to obtain the reason why the prepare failed.

Syntax

```
            duckdb_state duckdb_prepare(
  duckdb_connection connection,
  const char *query,
  duckdb_prepared_statement *out_prepared_statement
);
```

Parameters

- `connection`: The connection object
- `query`: The SQL query to prepare
- `out_prepared_statement`: The resulting prepared statement object

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_destroy_prepare` Closes the prepared statement and de-allocates all memory allocated for the statement.

Syntax

```
            void duckdb_destroy_prepare(
  duckdb_prepared_statement *prepared_statement
);
```

Parameters

- `prepared_statement`: The prepared statement to destroy.

`duckdb_prepare_error` Returns the error message associated with the given prepared statement. If the prepared statement has no error message, this returns `nullptr` instead.

The error message should not be freed. It will be de-allocated when `duckdb_destroy_prepare` is called.

Syntax

```
            const char *duckdb_prepare_error(
  duckdb_prepared_statement prepared_statement
);
```

Parameters

- `prepared_statement`: The prepared statement to obtain the error from.

Return Value The error message, or `nullptr` if there is none.

`duckdb_nparams` Returns the number of parameters that can be provided to the given prepared statement.

Returns 0 if the query was not successfully prepared.

Syntax

```
            idx_t duckdb_nparams(
  duckdb_prepared_statement prepared_statement
);
```

Parameters

- `prepared_statement`: The prepared statement to obtain the number of parameters for.

`duckdb_parameter_name` Returns the name used to identify the parameter The returned string should be freed using `duckdb_free`.

Returns NULL if the index is out of range for the provided prepared statement.

Syntax

```
           const char *duckdb_parameter_name(
  duckdb_prepared_statement prepared_statement,
  idx_t index
);
```

Parameters

- `prepared_statement`: The prepared statement for which to get the parameter name from.

`duckdb_param_type` Returns the parameter type for the parameter at the given index.

Returns `DUCKDB_TYPE_INVALID` if the parameter index is out of range or the statement was not successfully prepared.

Syntax

```
           duckdb_type duckdb_param_type(
  duckdb_prepared_statement prepared_statement,
  idx_t param_idx
);
```

Parameters

- `prepared_statement`: The prepared statement.
- `param_idx`: The parameter index.

Return Value The parameter type

`duckdb_param_logical_type` Returns the logical type for the parameter at the given index.

Returns `nullptr` if the parameter index is out of range or the statement was not successfully prepared.

The return type of this call should be destroyed with `duckdb_destroy_logical_type`.

Syntax

```
           duckdb_logical_type duckdb_param_logical_type(
  duckdb_prepared_statement prepared_statement,
  idx_t param_idx
);
```

Parameters

- `prepared_statement`: The prepared statement.
- `param_idx`: The parameter index.

Return Value The logical type of the parameter

`duckdb_clear_bindings` Clear the params bind to the prepared statement.

Syntax

```
            duckdb_state duckdb_clear_bindings(
  duckdb_prepared_statement prepared_statement
);
```

`duckdb_prepared_statement_type` Returns the statement type of the statement to be executed

Syntax

```
            duckdb_statement_type duckdb_prepared_statement_type(
  duckdb_prepared_statement statement
);
```

Parameters

- `statement`: The prepared statement.

Return Value duckdb_statement_type value or DUCKDB_STATEMENT_TYPE_INVALID

`duckdb_prepared_statement_column_count` Returns the number of columns present in a the result of the prepared statement. If any of the column types are invalid, the result will be 1.

Syntax

```
            idx_t duckdb_prepared_statement_column_count(
  duckdb_prepared_statement prepared_statement
);
```

Parameters

- `prepared_statement`: The prepared statement.

Return Value The number of columns present in the result of the prepared statement.

`duckdb_prepared_statement_column_name` Returns the name of the specified column of the result of the prepared_statement. The returned string should be freed using `duckdb_free`.

Returns `nullptr` if the column is out of range.

Syntax

```
            const char *duckdb_prepared_statement_column_name(
  duckdb_prepared_statement prepared_statement,
  idx_t col_idx
);
```

Parameters

- `prepared_statement`: The prepared statement.
- `col_idx`: The column index.

Return Value The column name of the specified column.

`duckdb_prepared_statement_column_logical_type` Returns the column type of the specified column of the result of the prepared_statement.

Returns `DUCKDB_TYPE_INVALID` if the column is out of range. The return type of this call should be destroyed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_prepared_statement_column_logical_type(
  duckdb_prepared_statement prepared_statement,
  idx_t col_idx
);
```

Parameters

- `prepared_statement`: The prepared statement to fetch the column type from.
- `col_idx`: The column index.

Return Value The logical type of the specified column.

`duckdb_prepared_statement_column_type` Returns the column type of the specified column of the result of the prepared_statement.

Returns `DUCKDB_TYPE_INVALID` if the column is out of range.

Syntax

```
            duckdb_type duckdb_prepared_statement_column_type(
  duckdb_prepared_statement prepared_statement,
  idx_t col_idx
);
```

Parameters

- `prepared_statement`: The prepared statement to fetch the column type from.
- `col_idx`: The column index.

Return Value The type of the specified column.

`duckdb_bind_value` Binds a value to the prepared statement at the specified index.

Syntax

```
            duckdb_state duckdb_bind_value(
  duckdb_prepared_statement prepared_statement,
  idx_t param_idx,
  duckdb_value val
);
```

`duckdb_bind_parameter_index` Retrieve the index of the parameter for the prepared statement, identified by name

Syntax

```
            duckdb_state duckdb_bind_parameter_index(
  duckdb_prepared_statement prepared_statement,
  idx_t *param_idx_out,
  const char *name
);
```

`duckdb_bind_boolean` Binds a bool value to the prepared statement at the specified index.

Syntax

```
            duckdb_state duckdb_bind_boolean(
  duckdb_prepared_statement prepared_statement,
  idx_t param_idx,
  bool val
);
```

`duckdb_bind_int8` Binds an int8_t value to the prepared statement at the specified index.

Syntax

```
            duckdb_state duckdb_bind_int8(
  duckdb_prepared_statement prepared_statement,
  idx_t param_idx,
  int8_t val
);
```

`duckdb_bind_int16` Binds an int16_t value to the prepared statement at the specified index.

Syntax

```
            duckdb_state duckdb_bind_int16(
  duckdb_prepared_statement prepared_statement,
  idx_t param_idx,
  int16_t val
);
```

`duckdb_bind_int32` Binds an int32_t value to the prepared statement at the specified index.

Syntax

```
            duckdb_state duckdb_bind_int32(
  duckdb_prepared_statement prepared_statement,
  idx_t param_idx,
  int32_t val
);
```

`duckdb_bind_int64` Binds an int64_t value to the prepared statement at the specified index.

Syntax

```
            duckdb_state duckdb_bind_int64(
  duckdb_prepared_statement prepared_statement,
  idx_t param_idx,
  int64_t val
);
```

`duckdb_bind_hugeint` Binds a duckdb_hugeint value to the prepared statement at the specified index.

Syntax

```
            duckdb_state duckdb_bind_hugeint(
  duckdb_prepared_statement prepared_statement,
  idx_t param_idx,
  duckdb_hugeint val
);
```

`duckdb_bind_uhugeint` Binds a duckdb_uhugeint value to the prepared statement at the specified index.

Syntax

```
            duckdb_state duckdb_bind_uhugeint(
  duckdb_prepared_statement prepared_statement,
  idx_t param_idx,
  duckdb_uhugeint val
);
```

`duckdb_bind_decimal` Binds a duckdb_decimal value to the prepared statement at the specified index.

Syntax

```
            duckdb_state duckdb_bind_decimal(
  duckdb_prepared_statement prepared_statement,
  idx_t param_idx,
  duckdb_decimal val
);
```

`duckdb_bind_uint8` Binds a uint8_t value to the prepared statement at the specified index.

Syntax

```
            duckdb_state duckdb_bind_uint8(
  duckdb_prepared_statement prepared_statement,
  idx_t param_idx,
  uint8_t val
);
```

`duckdb_bind_uint16` Binds a uint16_t value to the prepared statement at the specified index.

Syntax

```
            duckdb_state duckdb_bind_uint16(
  duckdb_prepared_statement prepared_statement,
  idx_t param_idx,
  uint16_t val
);
```

`duckdb_bind_uint32` Binds a uint32_t value to the prepared statement at the specified index.

Syntax

```
            duckdb_state duckdb_bind_uint32(
  duckdb_prepared_statement prepared_statement,
  idx_t param_idx,
  uint32_t val
);
```

`duckdb_bind_uint64` Binds a uint64_t value to the prepared statement at the specified index.

Syntax

```
            duckdb_state duckdb_bind_uint64(
  duckdb_prepared_statement prepared_statement,
  idx_t param_idx,
  uint64_t val
);
```

`duckdb_bind_float` Binds a float value to the prepared statement at the specified index.

Syntax

```
            duckdb_state duckdb_bind_float(
  duckdb_prepared_statement prepared_statement,
  idx_t param_idx,
  float val
);
```

`duckdb_bind_double` Binds a double value to the prepared statement at the specified index.

Syntax

```
            duckdb_state duckdb_bind_double(
  duckdb_prepared_statement prepared_statement,
  idx_t param_idx,
  double val
);
```

`duckdb_bind_date` Binds a duckdb_date value to the prepared statement at the specified index.

Syntax

```
            duckdb_state duckdb_bind_date(
  duckdb_prepared_statement prepared_statement,
  idx_t param_idx,
  duckdb_date val
);
```

`duckdb_bind_time` Binds a duckdb_time value to the prepared statement at the specified index.

Syntax

```
            duckdb_state duckdb_bind_time(
  duckdb_prepared_statement prepared_statement,
  idx_t param_idx,
  duckdb_time val
);
```

`duckdb_bind_timestamp` Binds a duckdb_timestamp value to the prepared statement at the specified index.

Syntax

```
            duckdb_state duckdb_bind_timestamp(
  duckdb_prepared_statement prepared_statement,
  idx_t param_idx,
  duckdb_timestamp val
);
```

`duckdb_bind_timestamp_tz` Binds a duckdb_timestamp value to the prepared statement at the specified index.

Syntax

```
            duckdb_state duckdb_bind_timestamp_tz(
  duckdb_prepared_statement prepared_statement,
  idx_t param_idx,
  duckdb_timestamp val
);
```

`duckdb_bind_interval` Binds a duckdb_interval value to the prepared statement at the specified index.

Syntax

```
            duckdb_state duckdb_bind_interval(
  duckdb_prepared_statement prepared_statement,
  idx_t param_idx,
  duckdb_interval val
);
```

`duckdb_bind_varchar` Binds a null-terminated varchar value to the prepared statement at the specified index.

Syntax

```
            duckdb_state duckdb_bind_varchar(
  duckdb_prepared_statement prepared_statement,
  idx_t param_idx,
  const char *val
);
```

`duckdb_bind_varchar_length` Binds a varchar value to the prepared statement at the specified index.

Syntax

```
            duckdb_state duckdb_bind_varchar_length(
  duckdb_prepared_statement prepared_statement,
  idx_t param_idx,
  const char *val,
  idx_t length
);
```

`duckdb_bind_blob` Binds a blob value to the prepared statement at the specified index.

Syntax

```
            duckdb_state duckdb_bind_blob(
  duckdb_prepared_statement prepared_statement,
  idx_t param_idx,
  const void *data,
  idx_t length
);
```

`duckdb_bind_null` Binds a NULL value to the prepared statement at the specified index.

Syntax

```
            duckdb_state duckdb_bind_null(
  duckdb_prepared_statement prepared_statement,
  idx_t param_idx
);
```

`duckdb_execute_prepared` Executes the prepared statement with the given bound parameters, and returns a materialized query result.

This method can be called multiple times for each prepared statement, and the parameters can be modified between calls to this function.

Note that the result must be freed with `duckdb_destroy_result`.

Syntax

```
            duckdb_state duckdb_execute_prepared(
  duckdb_prepared_statement prepared_statement,
  duckdb_result *out_result
);
```

Parameters

- `prepared_statement`: The prepared statement to execute.
- `out_result`: The query result.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_execute_prepared_streaming`

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Executes the prepared statement with the given bound parameters, and returns an optionally-streaming query result. To determine if the resulting query was in fact streamed, use `duckdb_result_is_streaming`

This method can be called multiple times for each prepared statement, and the parameters can be modified between calls to this function.

Note that the result must be freed with `duckdb_destroy_result`.

Syntax

```
            duckdb_state duckdb_execute_prepared_streaming(
  duckdb_prepared_statement prepared_statement,
  duckdb_result *out_result
);
```

Parameters

- `prepared_statement`: The prepared statement to execute.
- `out_result`: The query result.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_extract_statements` Extract all statements from a query. Note that after calling `duckdb_extract_statements`, the extracted statements should always be destroyed using `duckdb_destroy_extracted`, even if no statements were extracted.

If the extract fails, `duckdb_extract_statements_error` can be called to obtain the reason why the extract failed.

Syntax

```
            idx_t duckdb_extract_statements(
  duckdb_connection connection,
  const char *query,
  duckdb_extracted_statements *out_extracted_statements
);
```

Parameters

- `connection`: The connection object
- `query`: The SQL query to extract
- `out_extracted_statements`: The resulting extracted statements object

Return Value The number of extracted statements or 0 on failure.

`duckdb_prepare_extracted_statement` Prepare an extracted statement. Note that after calling `duckdb_prepare_extracted_statement`, the prepared statement should always be destroyed using `duckdb_destroy_prepare`, even if the prepare fails.

If the prepare fails, `duckdb_prepare_error` can be called to obtain the reason why the prepare failed.

Syntax

```
            duckdb_state duckdb_prepare_extracted_statement(
  duckdb_connection connection,
  duckdb_extracted_statements extracted_statements,
  idx_t index,
  duckdb_prepared_statement *out_prepared_statement
);
```

Parameters

- `connection`: The connection object
- `extracted_statements`: The extracted statements object
- `index`: The index of the extracted statement to prepare
- `out_prepared_statement`: The resulting prepared statement object

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_extract_statements_error` Returns the error message contained within the extracted statements. The result of this function must not be freed. It will be cleaned up when `duckdb_destroy_extracted` is called.

Syntax

```
            const char *duckdb_extract_statements_error(
  duckdb_extracted_statements extracted_statements
);
```

Parameters

- `extracted_statements`: The extracted statements to fetch the error from.

Return Value The error of the extracted statements.

`duckdb_destroy_extracted` De-allocates all memory allocated for the extracted statements.

Syntax

```
            void duckdb_destroy_extracted(
  duckdb_extracted_statements *extracted_statements
);
```

Parameters

- `extracted_statements`: The extracted statements to destroy.

`duckdb_pending_prepared` Executes the prepared statement with the given bound parameters, and returns a pending result. The pending result represents an intermediate structure for a query that is not yet fully executed. The pending result can be used to incrementally execute a query, returning control to the client between tasks.

Note that after calling `duckdb_pending_prepared`, the pending result should always be destroyed using `duckdb_destroy_pending`, even if this function returns DuckDBError.

Syntax

```
           duckdb_state duckdb_pending_prepared(
  duckdb_prepared_statement prepared_statement,
  duckdb_pending_result *out_result
);
```

Parameters

- `prepared_statement`: The prepared statement to execute.
- `out_result`: The pending query result.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_pending_prepared_streaming`

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Executes the prepared statement with the given bound parameters, and returns a pending result. This pending result will create a streaming duckdb_result when executed. The pending result represents an intermediate structure for a query that is not yet fully executed.

Note that after calling `duckdb_pending_prepared_streaming`, the pending result should always be destroyed using `duckdb_destroy_pending`, even if this function returns DuckDBError.

Syntax

```
           duckdb_state duckdb_pending_prepared_streaming(
  duckdb_prepared_statement prepared_statement,
  duckdb_pending_result *out_result
);
```

Parameters

- `prepared_statement`: The prepared statement to execute.
- `out_result`: The pending query result.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_destroy_pending` Closes the pending result and de-allocates all memory allocated for the result.

Syntax

```
           void duckdb_destroy_pending(
  duckdb_pending_result *pending_result
);
```

Parameters

- `pending_result`: The pending result to destroy.

`duckdb_pending_error` Returns the error message contained within the pending result.

The result of this function must not be freed. It will be cleaned up when `duckdb_destroy_pending` is called.

Syntax

```
            const char *duckdb_pending_error(
  duckdb_pending_result pending_result
);
```

Parameters

- `pending_result`: The pending result to fetch the error from.

Return Value The error of the pending result.

`duckdb_pending_execute_task` Executes a single task within the query, returning whether or not the query is ready.

If this returns DUCKDB_PENDING_RESULT_READY, the duckdb_execute_pending function can be called to obtain the result. If this returns DUCKDB_PENDING_RESULT_NOT_READY, the duckdb_pending_execute_task function should be called again. If this returns DUCKDB_PENDING_ERROR, an error occurred during execution.

The error message can be obtained by calling duckdb_pending_error on the pending_result.

Syntax

```
            duckdb_pending_state duckdb_pending_execute_task(
  duckdb_pending_result pending_result
);
```

Parameters

- `pending_result`: The pending result to execute a task within.

Return Value The state of the pending result after the execution.

`duckdb_pending_execute_check_state` If this returns DUCKDB_PENDING_RESULT_READY, the duckdb_execute_pending function can be called to obtain the result. If this returns DUCKDB_PENDING_RESULT_NOT_READY, the duckdb_pending_execute_check_state function should be called again. If this returns DUCKDB_PENDING_ERROR, an error occurred during execution.

The error message can be obtained by calling duckdb_pending_error on the pending_result.

Syntax

```
            duckdb_pending_state duckdb_pending_execute_check_state(
  duckdb_pending_result pending_result
);
```

Parameters

- `pending_result`: The pending result.

Return Value The state of the pending result.

`duckdb_execute_pending` Fully execute a pending query result, returning the final query result.

If duckdb_pending_execute_task has been called until DUCKDB_PENDING_RESULT_READY was returned, this will return fast. Otherwise, all remaining tasks must be executed first.

Note that the result must be freed with `duckdb_destroy_result`.

Syntax

```
            duckdb_state duckdb_execute_pending(
  duckdb_pending_result pending_result,
  duckdb_result *out_result
);
```

Parameters

- `pending_result`: The pending result to execute.
- `out_result`: The result object.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_pending_execution_is_finished` Returns whether a duckdb_pending_state is finished executing. For example if `pending_state` is DUCKDB_PENDING_RESULT_READY, this function will return true.

Syntax

```
            bool duckdb_pending_execution_is_finished(
  duckdb_pending_state pending_state
);
```

Parameters

- `pending_state`: The pending state on which to decide whether to finish execution.

Return Value Boolean indicating pending execution should be considered finished.

`duckdb_destroy_value` Destroys the value and de-allocates all memory allocated for that type.

Syntax

```
            void duckdb_destroy_value(
  duckdb_value *value
);
```

Parameters

- `value`: The value to destroy.

`duckdb_create_varchar` Creates a value from a null-terminated string

Syntax

```
            duckdb_value duckdb_create_varchar(
  const char *text
);
```

Parameters

- `text`: The null-terminated string

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_varchar_length` Creates a value from a string

Syntax

```
            duckdb_value duckdb_create_varchar_length(
  const char *text,
  idx_t length
);
```

Parameters

- `text`: The text
- `length`: The length of the text

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_bool` Creates a value from a boolean

Syntax

```
            duckdb_value duckdb_create_bool(
  bool input
);
```

Parameters

- `input`: The boolean value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_int8` Creates a value from an int8_t (a tinyint)

Syntax

```
            duckdb_value duckdb_create_int8(
  int8_t input
);
```

Parameters

- `input`: The tinyint value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_uint8` Creates a value from a uint8_t (a utinyint)

Syntax

```
            duckdb_value duckdb_create_uint8(
  uint8_t input
);
```

Parameters

- `input`: The utinyint value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_int16` Creates a value from an int16_t (a smallint)

Syntax

```
            duckdb_value duckdb_create_int16(
  int16_t input
);
```

Parameters

- `input`: The smallint value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_uint16` Creates a value from a uint16_t (a usmallint)

Syntax

```
            duckdb_value duckdb_create_uint16(
  uint16_t input
);
```

Parameters

- `input`: The usmallint value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_int32` Creates a value from an int32_t (an integer)

Syntax

```
            duckdb_value duckdb_create_int32(
  int32_t input
);
```

Parameters

- `input`: The integer value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_uint32` Creates a value from a uint32_t (a uinteger)

Syntax

```
            duckdb_value duckdb_create_uint32(
  uint32_t input
);
```

Parameters

- `input`: The uinteger value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_uint64` Creates a value from a uint64_t (a ubigint)

Syntax

```
            duckdb_value duckdb_create_uint64(
  uint64_t input
);
```

Parameters

- `input`: The ubigint value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_int64` Creates a value from an int64

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

Syntax

```
            duckdb_value duckdb_create_int64(
  int64_t val
);
```

`duckdb_create_hugeint` Creates a value from a hugeint

Syntax

```
            duckdb_value duckdb_create_hugeint(
  duckdb_hugeint input
);
```

Parameters

- `input`: The hugeint value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_uhugeint` Creates a value from a uhugeint

Syntax

```
            duckdb_value duckdb_create_uhugeint(
  duckdb_uhugeint input
);
```

Parameters

- `input`: The uhugeint value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_bignum` Creates a BIGNUM value from a duckdb_bignum

Syntax

```
            duckdb_value duckdb_create_bignum(
  duckdb_bignum input
);
```

Parameters

- `input`: The duckdb_bignum value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_decimal` Creates a DECIMAL value from a duckdb_decimal

Syntax

```
            duckdb_value duckdb_create_decimal(
  duckdb_decimal input
);
```

Parameters

- `input`: The duckdb_decimal value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_float` Creates a value from a float

Syntax

```
            duckdb_value duckdb_create_float(
  float input
);
```

Parameters

- `input`: The float value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_double` Creates a value from a double

Syntax

```
            duckdb_value duckdb_create_double(
  double input
);
```

Parameters

- `input`: The double value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_date` Creates a value from a date

Syntax

```
            duckdb_value duckdb_create_date(
  duckdb_date input
);
```

Parameters

- `input`: The date value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_time` Creates a value from a time

Syntax

```
            duckdb_value duckdb_create_time(
  duckdb_time input
);
```

Parameters

- `input`: The time value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_time_ns` Creates a value from a time_ns

Syntax

```
            duckdb_value duckdb_create_time_ns(
  duckdb_time_ns input
);
```

Parameters

- `input`: The time value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_time_tz_value` Creates a value from a time_tz. Not to be confused with `duckdb_create_time_tz`, which creates a duckdb_time_tz_t.

Syntax

```
            duckdb_value duckdb_create_time_tz_value(
  duckdb_time_tz value
);
```

Parameters

- `value`: The time_tz value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_timestamp` Creates a TIMESTAMP value from a duckdb_timestamp

Syntax

```
            duckdb_value duckdb_create_timestamp(
  duckdb_timestamp input
);
```

Parameters

- `input`: The duckdb_timestamp value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_timestamp_tz` Creates a TIMESTAMP_TZ value from a duckdb_timestamp

Syntax

```
            duckdb_value duckdb_create_timestamp_tz(
  duckdb_timestamp input
);
```

Parameters

- `input`: The duckdb_timestamp value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_timestamp_s` Creates a TIMESTAMP_S value from a duckdb_timestamp_s

Syntax

```
            duckdb_value duckdb_create_timestamp_s(
  duckdb_timestamp_s input
);
```

Parameters

- `input`: The duckdb_timestamp_s value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_timestamp_ms` Creates a TIMESTAMP_MS value from a duckdb_timestamp_ms

Syntax

```
            duckdb_value duckdb_create_timestamp_ms(
  duckdb_timestamp_ms input
);
```

Parameters

- `input`: The duckdb_timestamp_ms value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_timestamp_ns` Creates a TIMESTAMP_NS value from a duckdb_timestamp_ns

Syntax

```
            duckdb_value duckdb_create_timestamp_ns(
  duckdb_timestamp_ns input
);
```

Parameters

- `input`: The duckdb_timestamp_ns value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_interval` Creates a value from an interval

Syntax

```
            duckdb_value duckdb_create_interval(
  duckdb_interval input
);
```

Parameters

- `input`: The interval value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_blob` Creates a value from a blob

Syntax

```
            duckdb_value duckdb_create_blob(
  const uint8_t *data,
  idx_t length
);
```

Parameters

- `data`: The blob data
- `length`: The length of the blob data

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_bit` Creates a BIT value from a duckdb_bit

Syntax

```
            duckdb_value duckdb_create_bit(
  duckdb_bit input
);
```

Parameters

- `input`: The duckdb_bit value

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_create_uuid` Creates a UUID value from a uhugeint

Syntax

```
            duckdb_value duckdb_create_uuid(
  duckdb_uhugeint input
);
```

Parameters

- `input`: The duckdb_uhugeint containing the UUID

Return Value The value. This must be destroyed with `duckdb_destroy_value`.

`duckdb_get_bool` Returns the boolean value of the given value.

Syntax

```
            bool duckdb_get_bool(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a boolean

Return Value A boolean, or false if the value cannot be converted

`duckdb_get_int8` Returns the int8_t value of the given value.

Syntax

```
            int8_t duckdb_get_int8(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a tinyint

Return Value A int8_t, or MinValue if the value cannot be converted

`duckdb_get_uint8` Returns the uint8_t value of the given value.

Syntax

```
            uint8_t duckdb_get_uint8(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a utinyint

Return Value A uint8_t, or MinValue if the value cannot be converted

`duckdb_get_int16` Returns the int16_t value of the given value.

Syntax

```
            int16_t duckdb_get_int16(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a smallint

Return Value A int16_t, or MinValue if the value cannot be converted

`duckdb_get_uint16`

Returns the uint16_t value of the given value.

Syntax

```
            uint16_t duckdb_get_uint16(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a usmallint

Return Value A uint16_t, or MinValue if the value cannot be converted

`duckdb_get_int32`

Returns the int32_t value of the given value.

Syntax

```
            int32_t duckdb_get_int32(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing an integer

Return Value A int32_t, or MinValue if the value cannot be converted

`duckdb_get_uint32`

Returns the uint32_t value of the given value.

Syntax

```
            uint32_t duckdb_get_uint32(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a uinteger

Return Value A uint32_t, or MinValue if the value cannot be converted

`duckdb_get_int64`

Returns the int64_t value of the given value.

Syntax

```
            int64_t duckdb_get_int64(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a bigint

Return Value A int64_t, or MinValue if the value cannot be converted

`duckdb_get_uint64`

Returns the uint64_t value of the given value.

Syntax

```
            uint64_t duckdb_get_uint64(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a ubigint

Return Value A uint64_t, or MinValue if the value cannot be converted

`duckdb_get_hugeint`

Returns the hugeint value of the given value.

Syntax

```
            duckdb_hugeint duckdb_get_hugeint(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a hugeint

Return Value A duckdb_hugeint, or MinValue if the value cannot be converted

`duckdb_get_uhugeint`

Returns the uhugeint value of the given value.

Syntax

```
            duckdb_uhugeint duckdb_get_uhugeint(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a uhugeint

Return Value A duckdb_uhugeint, or MinValue if the value cannot be converted

`duckdb_get_bignum` Returns the duckdb_bignum value of the given value. The `data` field must be destroyed with `duckdb_free`.

Syntax

```
            duckdb_bignum duckdb_get_bignum(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a BIGNUM

Return Value A duckdb_bignum. The `data` field must be destroyed with `duckdb_free`.

`duckdb_get_decimal` Returns the duckdb_decimal value of the given value.

Syntax

```
            duckdb_decimal duckdb_get_decimal(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a DECIMAL

Return Value A duckdb_decimal, or MinValue if the value cannot be converted

`duckdb_get_float` Returns the float value of the given value.

Syntax

```
            float duckdb_get_float(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a float

Return Value A float, or NAN if the value cannot be converted

`duckdb_get_double` Returns the double value of the given value.

Syntax

```
            double duckdb_get_double(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a double

Return Value A double, or NAN if the value cannot be converted

`duckdb_get_date` Returns the date value of the given value.

Syntax

```
            duckdb_date duckdb_get_date(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a date

Return Value A duckdb_date, or MinValue if the value cannot be converted

`duckdb_get_time` Returns the time value of the given value.

Syntax

```
            duckdb_time duckdb_get_time(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a time

Return Value A duckdb_time, or MinValue if the value cannot be converted

`duckdb_get_time_ns` Returns the time_ns value of the given value.

Syntax

```
            duckdb_time_ns duckdb_get_time_ns(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a time_ns

Return Value A duckdb_time_ns, or MinValue if the value cannot be converted

`duckdb_get_time_tz` Returns the time_tz value of the given value.

Syntax

```
            duckdb_time_tz duckdb_get_time_tz(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a time_tz

Return Value A duckdb_time_tz, or MinValue if the value cannot be converted

`duckdb_get_timestamp` Returns the TIMESTAMP value of the given value.

Syntax

```
            duckdb_timestamp duckdb_get_timestamp(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a TIMESTAMP

Return Value A duckdb_timestamp, or MinValue if the value cannot be converted

`duckdb_get_timestamp_tz` Returns the TIMESTAMP_TZ value of the given value.

Syntax

```
            duckdb_timestamp duckdb_get_timestamp_tz(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a TIMESTAMP_TZ

Return Value A duckdb_timestamp, or MinValue if the value cannot be converted

`duckdb_get_timestamp_s` Returns the duckdb_timestamp_s value of the given value.

Syntax

```
            duckdb_timestamp_s duckdb_get_timestamp_s(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a TIMESTAMP_S

Return Value A duckdb_timestamp_s, or MinValue if the value cannot be converted

`duckdb_get_timestamp_ms` Returns the duckdb_timestamp_ms value of the given value.

Syntax

```
            duckdb_timestamp_ms duckdb_get_timestamp_ms(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a TIMESTAMP_MS

Return Value A duckdb_timestamp_ms, or MinValue if the value cannot be converted

`duckdb_get_timestamp_ns` Returns the duckdb_timestamp_ns value of the given value.

Syntax

```
            duckdb_timestamp_ns duckdb_get_timestamp_ns(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a TIMESTAMP_NS

Return Value A duckdb_timestamp_ns, or MinValue if the value cannot be converted

`duckdb_get_interval` Returns the interval value of the given value.

Syntax

```
            duckdb_interval duckdb_get_interval(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a interval

Return Value A duckdb_interval, or MinValue if the value cannot be converted

`duckdb_get_value_type` Returns the type of the given value. The type is valid as long as the value is not destroyed. The type itself must not be destroyed.

Syntax

```
            duckdb_logical_type duckdb_get_value_type(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value

Return Value A duckdb_logical_type.

`duckdb_get_blob` Returns the blob value of the given value.

Syntax

```
            duckdb_blob duckdb_get_blob(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a blob

Return Value A duckdb_blob

`duckdb_get_bit` Returns the duckdb_bit value of the given value. The `data` field must be destroyed with `duckdb_free`.

Syntax

```
            duckdb_bit duckdb_get_bit(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a BIT

Return Value A duckdb_bit

`duckdb_get_uuid` Returns a duckdb_uhugeint representing the UUID value of the given value.

Syntax

```
            duckdb_uhugeint duckdb_get_uuid(
  duckdb_value val
);
```

Parameters

- `val`: A duckdb_value containing a UUID

Return Value A duckdb_uhugeint representing the UUID value

`duckdb_get_varchar` Obtains a string representation of the given value. The result must be destroyed with `duckdb_free`.

Syntax

```
            char *duckdb_get_varchar(
  duckdb_value value
);
```

Parameters

- `value`: The value

Return Value The string value. This must be destroyed with `duckdb_free`.

`duckdb_create_struct_value` Creates a struct value from a type and an array of values. Must be destroyed with `duckdb_destroy_value`.

Syntax

```
            duckdb_value duckdb_create_struct_value(
  duckdb_logical_type type,
  duckdb_value *values
);
```

Parameters

- `type`: The type of the struct
- `values`: The values for the struct fields

Return Value The struct value, or nullptr, if any child type is `DUCKDB_TYPE_ANY` or `DUCKDB_TYPE_INVALID`.

`duckdb_create_list_value` Creates a list value from a child (element) type and an array of values of length `value_count`. Must be destroyed with `duckdb_destroy_value`.

Syntax

```
            duckdb_value duckdb_create_list_value(
  duckdb_logical_type type,
  duckdb_value *values,
  idx_t value_count
);
```

Parameters

- `type`: The type of the list
- `values`: The values for the list
- `value_count`: The number of values in the list

Return Value The list value, or nullptr, if the child type is `DUCKDB_TYPE_ANY` or `DUCKDB_TYPE_INVALID`.

`duckdb_create_array_value` Creates an array value from a child (element) type and an array of values of length `value_count`. Must be destroyed with `duckdb_destroy_value`.

Syntax

```
            duckdb_value duckdb_create_array_value(
  duckdb_logical_type type,
  duckdb_value *values,
  idx_t value_count
);
```

Parameters

- `type`: The type of the array
- `values`: The values for the array
- `value_count`: The number of values in the array

Return Value The array value, or nullptr, if the child type is `DUCKDB_TYPE_ANY` or `DUCKDB_TYPE_INVALID`.

`duckdb_create_map_value` Creates a map value from a map type and two arrays, one for the keys and one for the values, each of length `entry_count`. Must be destroyed with `duckdb_destroy_value`.

Syntax

```
            duckdb_value duckdb_create_map_value(
  duckdb_logical_type map_type,
  duckdb_value *keys,
  duckdb_value *values,
  idx_t entry_count
);
```

Parameters

- `map_type`: The map type
- `keys`: The keys of the map
- `values`: The values of the map
- `entry_count`: The number of entries (key-value pairs) in the map

Return Value The map value, or nullptr, if the parameters are invalid.

`duckdb_create_union_value` Creates a union value from a union type, a tag index, and a value. Must be destroyed with `duckdb_destroy_value`.

Syntax

```
            duckdb_value duckdb_create_union_value(
  duckdb_logical_type union_type,
  idx_t tag_index,
  duckdb_value value
);
```

Parameters

- `union_type`: The union type
- `tag_index`: The index of the tag of the union
- `value`: The value of the union for that tag

Return Value The union value, or nullptr, if the parameters are invalid.

`duckdb_get_map_size` Returns the number of elements in a MAP value.

Syntax

```
            idx_t duckdb_get_map_size(
  duckdb_value value
);
```

Parameters

- `value`: The MAP value.

Return Value The number of elements in the map.

`duckdb_get_map_key` Returns the MAP key at index as a duckdb_value.

Syntax

```
            duckdb_value duckdb_get_map_key(
  duckdb_value value,
  idx_t index
);
```

Parameters

- `value`: The MAP value.
- `index`: The index of the key.

Return Value The key as a duckdb_value.

`duckdb_get_map_value` Returns the MAP value at index as a duckdb_value.

Syntax

```
            duckdb_value duckdb_get_map_value(
  duckdb_value value,
  idx_t index
);
```

Parameters

- `value`: The MAP value.
- `index`: The index of the value.

Return Value The value as a duckdb_value.

`duckdb_is_null_value` Returns whether the value's type is SQLNULL or not.

Syntax

```
            bool duckdb_is_null_value(
  duckdb_value value
);
```

Parameters

- `value`: The value to check.

Return Value True, if the value's type is SQLNULL, otherwise false.

`duckdb_create_null_value` Creates a value of type SQLNULL.

Return Value The duckdb_value representing SQLNULL. This must be destroyed with `duckdb_destroy_value`.

Syntax

```
            duckdb_value duckdb_create_null_value(

);
```

`duckdb_get_list_size` Returns the number of elements in a LIST value.

Syntax

```
            idx_t duckdb_get_list_size(
  duckdb_value value
);
```

Parameters

- `value`: The LIST value.

Return Value The number of elements in the list.

`duckdb_get_list_child` Returns the LIST child at index as a duckdb_value.

Syntax

```
            duckdb_value duckdb_get_list_child(
  duckdb_value value,
  idx_t index
);
```

Parameters

- `value`: The LIST value.
- `index`: The index of the child.

Return Value The child as a duckdb_value.

`duckdb_create_enum_value` Creates an enum value from a type and a value. Must be destroyed with `duckdb_destroy_value`.

Syntax

```
            duckdb_value duckdb_create_enum_value(
  duckdb_logical_type type,
  uint64_t value
);
```

Parameters

- `type`: The type of the enum
- `value`: The value for the enum

Return Value The enum value, or nullptr.

`duckdb_get_enum_value` Returns the enum value of the given value.

Syntax

```
            uint64_t duckdb_get_enum_value(
  duckdb_value value
);
```

Parameters

- `value`: A duckdb_value containing an enum

Return Value A uint64_t, or MinValue if the value cannot be converted

`duckdb_get_struct_child` Returns the STRUCT child at index as a duckdb_value.

Syntax

```
            duckdb_value duckdb_get_struct_child(
  duckdb_value value,
  idx_t index
);
```

Parameters

- `value`: The STRUCT value.
- `index`: The index of the child.

Return Value The child as a duckdb_value.

`duckdb_value_to_string` Returns the SQL string representation of the given value.

Syntax

```
            char *duckdb_value_to_string(
  duckdb_value value
);
```

Parameters

- `value`: A duckdb_value.

Return Value The SQL string representation as a null-terminated string. The result must be freed with `duckdb_free`.

`duckdb_create_logical_type` Creates a `duckdb_logical_type` from a primitive type. The resulting logical type must be destroyed with `duckdb_destroy_logical_type`.

Returns an invalid logical type, if type is: `DUCKDB_TYPE_INVALID`, `DUCKDB_TYPE_DECIMAL`, `DUCKDB_TYPE_ENUM`, `DUCKDB_TYPE_LIST`, `DUCKDB_TYPE_STRUCT`, `DUCKDB_TYPE_MAP`, `DUCKDB_TYPE_ARRAY`, or `DUCKDB_TYPE_UNION`.

Syntax

```
            duckdb_logical_type duckdb_create_logical_type(
  duckdb_type type
);
```

Parameters

- `type`: The primitive type to create.

Return Value The logical type.

`duckdb_logical_type_get_alias` Returns the alias of a duckdb_logical_type, if set, else `nullptr`. The result must be destroyed with `duckdb_free`.

Syntax

```
            char *duckdb_logical_type_get_alias(
  duckdb_logical_type type
);
```

Parameters

- `type`: The logical type

Return Value The alias or `nullptr`

`duckdb_logical_type_set_alias` Sets the alias of a duckdb_logical_type.

Syntax

```
            void duckdb_logical_type_set_alias(
  duckdb_logical_type type,
  const char *alias
);
```

Parameters

- `type`: The logical type
- `alias`: The alias to set

`duckdb_create_list_type` Creates a LIST type from its child type. The return type must be destroyed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_create_list_type(
  duckdb_logical_type type
);
```

Parameters

- `type`: The child type of the list

Return Value The logical type.

`duckdb_create_array_type` Creates an ARRAY type from its child type. The return type must be destroyed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_create_array_type(
  duckdb_logical_type type,
  idx_t array_size
);
```

Parameters

- `type`: The child type of the array.
- `array_size`: The number of elements in the array.

Return Value The logical type.

`duckdb_create_map_type` Creates a MAP type from its key type and value type. The return type must be destroyed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_create_map_type(
  duckdb_logical_type key_type,
  duckdb_logical_type value_type
);
```

Parameters

- `key_type`: The map's key type.
- `value_type`: The map's value type.

Return Value The logical type.

`duckdb_create_union_type` Creates a UNION type from the passed arrays. The return type must be destroyed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_create_union_type(
  duckdb_logical_type *member_types,
  const char **member_names,
  idx_t member_count
);
```

Parameters

- `member_types`: The array of union member types.
- `member_names`: The union member names.
- `member_count`: The number of union members.

Return Value The logical type.

`duckdb_create_struct_type` Creates a STRUCT type based on the member types and names. The resulting type must be destroyed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_create_struct_type(
  duckdb_logical_type *member_types,
  const char **member_names,
  idx_t member_count
);
```

Parameters

- `member_types`: The array of types of the struct members.
- `member_names`: The array of names of the struct members.
- `member_count`: The number of members of the struct.

Return Value The logical type.

`duckdb_create_enum_type` Creates an ENUM type from the passed member name array. The resulting type should be destroyed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_create_enum_type(
  const char **member_names,
  idx_t member_count
);
```

Parameters

- `member_names`: The array of names that the enum should consist of.
- `member_count`: The number of elements that were specified in the array.

Return Value

The logical type.

`duckdb_create_decimal_type`

Creates a DECIMAL type with the specified width and scale. The resulting type should be destroyed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_create_decimal_type(
  uint8_t width,
  uint8_t scale
);
```

Parameters

- `width`: The width of the decimal type
- `scale`: The scale of the decimal type

Return Value

The logical type.

`duckdb_get_type_id`

Retrieves the enum `duckdb_type` of a `duckdb_logical_type`.

Syntax

```
            duckdb_type duckdb_get_type_id(
  duckdb_logical_type type
);
```

Parameters

- `type`: The logical type.

Return Value

The `duckdb_type` id.

`duckdb_decimal_width`

Retrieves the width of a decimal type.

Syntax

```
            uint8_t duckdb_decimal_width(
  duckdb_logical_type type
);
```

Parameters

- `type`: The logical type object

Return Value

The width of the decimal type

`duckdb_decimal_scale` Retrieves the scale of a decimal type.

Syntax

```
            uint8_t duckdb_decimal_scale(
  duckdb_logical_type type
);
```

Parameters

- `type`: The logical type object

Return Value The scale of the decimal type

`duckdb_decimal_internal_type` Retrieves the internal storage type of a decimal type.

Syntax

```
            duckdb_type duckdb_decimal_internal_type(
  duckdb_logical_type type
);
```

Parameters

- `type`: The logical type object

Return Value The internal type of the decimal type

`duckdb_enum_internal_type` Retrieves the internal storage type of an enum type.

Syntax

```
            duckdb_type duckdb_enum_internal_type(
  duckdb_logical_type type
);
```

Parameters

- `type`: The logical type object

Return Value The internal type of the enum type

`duckdb_enum_dictionary_size` Retrieves the dictionary size of the enum type.

Syntax

```
            uint32_t duckdb_enum_dictionary_size(
  duckdb_logical_type type
);
```

Parameters

- `type`: The logical type object

Return Value The dictionary size of the enum type

`duckdb_enum_dictionary_value` Retrieves the dictionary value at the specified position from the enum.

The result must be freed with `duckdb_free`.

Syntax

```
            char *duckdb_enum_dictionary_value(
  duckdb_logical_type type,
  idx_t index
);
```

Parameters

- `type`: The logical type object
- `index`: The index in the dictionary

Return Value The string value of the enum type. Must be freed with `duckdb_free`.

`duckdb_list_type_child_type` Retrieves the child type of the given LIST type. Also accepts MAP types. The result must be freed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_list_type_child_type(
  duckdb_logical_type type
);
```

Parameters

- `type`: The logical type, either LIST or MAP.

Return Value The child type of the LIST or MAP type.

`duckdb_array_type_child_type` Retrieves the child type of the given ARRAY type.

The result must be freed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_array_type_child_type(
  duckdb_logical_type type
);
```

Parameters

- `type`: The logical type. Must be ARRAY.

Return Value The child type of the ARRAY type.

`duckdb_array_type_array_size` Retrieves the array size of the given array type.

Syntax

```
            idx_t duckdb_array_type_array_size(
  duckdb_logical_type type
);
```

Parameters

- `type`: The logical type object

Return Value The fixed number of elements the values of this array type can store.

`duckdb_map_type_key_type` Retrieves the key type of the given map type.

The result must be freed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_map_type_key_type(
  duckdb_logical_type type
);
```

Parameters

- `type`: The logical type object

Return Value The key type of the map type. Must be destroyed with `duckdb_destroy_logical_type`.

`duckdb_map_type_value_type` Retrieves the value type of the given map type.

The result must be freed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_map_type_value_type(
  duckdb_logical_type type
);
```

Parameters

- `type`: The logical type object

Return Value The value type of the map type. Must be destroyed with `duckdb_destroy_logical_type`.

`duckdb_struct_type_child_count` Returns the number of children of a struct type.

Syntax

```
            idx_t duckdb_struct_type_child_count(
  duckdb_logical_type type
);
```

Parameters

- `type`: The logical type object

Return Value The number of children of a struct type.

`duckdb_struct_type_child_name` Retrieves the name of the struct child.

The result must be freed with `duckdb_free`.

Syntax

```
            char *duckdb_struct_type_child_name(
  duckdb_logical_type type,
  idx_t index
);
```

Parameters

- `type`: The logical type object
- `index`: The child index

Return Value The name of the struct type. Must be freed with `duckdb_free`.

`duckdb_struct_type_child_type` Retrieves the child type of the given struct type at the specified index.

The result must be freed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_struct_type_child_type(
  duckdb_logical_type type,
  idx_t index
);
```

Parameters

- `type`: The logical type object
- `index`: The child index

Return Value The child type of the struct type. Must be destroyed with `duckdb_destroy_logical_type`.

`duckdb_union_type_member_count` Returns the number of members that the union type has.

Syntax

```
            idx_t duckdb_union_type_member_count(
  duckdb_logical_type type
);
```

Parameters

- `type`: The logical type (union) object

Return Value The number of members of a union type.

`duckdb_union_type_member_name` Retrieves the name of the union member.

The result must be freed with `duckdb_free`.

Syntax

```
            char *duckdb_union_type_member_name(
  duckdb_logical_type type,
  idx_t index
);
```

Parameters

- `type`: The logical type object
- `index`: The child index

Return Value The name of the union member. Must be freed with `duckdb_free`.

`duckdb_union_type_member_type` Retrieves the child type of the given union member at the specified index.

The result must be freed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_union_type_member_type(
  duckdb_logical_type type,
  idx_t index
);
```

Parameters

- `type`: The logical type object
- `index`: The child index

Return Value The child type of the union member. Must be destroyed with `duckdb_destroy_logical_type`.

`duckdb_destroy_logical_type` Destroys the logical type and de-allocates all memory allocated for that type.

Syntax

```
            void duckdb_destroy_logical_type(
  duckdb_logical_type *type
);
```

Parameters

- `type`: The logical type to destroy.

`duckdb_register_logical_type` Registers a custom type within the given connection. The type must have an alias

Syntax

```
            duckdb_state duckdb_register_logical_type(
  duckdb_connection con,
  duckdb_logical_type type,
  duckdb_create_type_info info
);
```

Parameters

- `con`: The connection to use
- `type`: The custom type to register

Return Value Whether or not the registration was successful.

`duckdb_create_data_chunk` Creates an empty data chunk with the specified column types. The result must be destroyed with `duckdb_destroy_data_chunk`.

Syntax

```
            duckdb_data_chunk duckdb_create_data_chunk(
  duckdb_logical_type *types,
  idx_t column_count
);
```

Parameters

- `types`: An array of column types. Column types can not contain ANY and INVALID types.
- `column_count`: The number of columns.

Return Value The data chunk.

`duckdb_destroy_data_chunk` Destroys the data chunk and de-allocates all memory allocated for that chunk.

Syntax

```
            void duckdb_destroy_data_chunk(
  duckdb_data_chunk *chunk
);
```

Parameters

- chunk: The data chunk to destroy.

`duckdb_data_chunk_reset` Resets a data chunk, clearing the validity masks and setting the cardinality of the data chunk to 0. After calling this method, you must call `duckdb_vector_get_validity` and `duckdb_vector_get_data` to obtain current data and validity pointers

Syntax

```
            void duckdb_data_chunk_reset(
  duckdb_data_chunk chunk
);
```

Parameters

- chunk: The data chunk to reset.

`duckdb_data_chunk_get_column_count` Retrieves the number of columns in a data chunk.

Syntax

```
            idx_t duckdb_data_chunk_get_column_count(
  duckdb_data_chunk chunk
);
```

Parameters

- chunk: The data chunk to get the data from

Return Value The number of columns in the data chunk

`duckdb_data_chunk_get_vector` Retrieves the vector at the specified column index in the data chunk.

The pointer to the vector is valid for as long as the chunk is alive. It does NOT need to be destroyed.

Syntax

```
            duckdb_vector duckdb_data_chunk_get_vector(
  duckdb_data_chunk chunk,
  idx_t col_idx
);
```

Parameters

- chunk: The data chunk to get the data from

Return Value The vector

`duckdb_data_chunk_get_size` Retrieves the current number of tuples in a data chunk.

Syntax

```
            idx_t duckdb_data_chunk_get_size(
  duckdb_data_chunk chunk
);
```

Parameters

- `chunk`: The data chunk to get the data from

Return Value The number of tuples in the data chunk

`duckdb_data_chunk_set_size` Sets the current number of tuples in a data chunk.

Syntax

```
            void duckdb_data_chunk_set_size(
  duckdb_data_chunk chunk,
  idx_t size
);
```

Parameters

- `chunk`: The data chunk to set the size in
- `size`: The number of tuples in the data chunk

`duckdb_create_vector` Creates a flat vector. Must be destroyed with `duckdb_destroy_vector`.

Syntax

```
            duckdb_vector duckdb_create_vector(
  duckdb_logical_type type,
  idx_t capacity
);
```

Parameters

- `type`: The logical type of the vector.
- `capacity`: The capacity of the vector.

Return Value The vector.

`duckdb_destroy_vector` Destroys the vector and de-allocates its memory.

Syntax

```
            void duckdb_destroy_vector(
  duckdb_vector *vector
);
```

Parameters

- `vector`: A pointer to the vector.

`duckdb_vector_get_column_type` Retrieves the column type of the specified vector.

The result must be destroyed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_vector_get_column_type(
  duckdb_vector vector
);
```

Parameters

- `vector`: The vector get the data from

Return Value The type of the vector

`duckdb_vector_get_data` Retrieves the data pointer of the vector.

The data pointer can be used to read or write values from the vector. How to read or write values depends on the type of the vector.

Syntax

```
            void *duckdb_vector_get_data(
  duckdb_vector vector
);
```

Parameters

- `vector`: The vector to get the data from

Return Value The data pointer

`duckdb_vector_get_validity` Retrieves the validity mask pointer of the specified vector.

If all values are valid, this function MIGHT return NULL!

The validity mask is a bitset that signifies null-ness within the data chunk. It is a series of uint64_t values, where each uint64_t value contains validity for 64 tuples. The bit is set to 1 if the value is valid (i.e., not NULL) or 0 if the value is invalid (i.e., NULL).

Validity of a specific value can be obtained like this:

idx_t entry_idx = row_idx / 64; idx_t idx_in_entry = row_idx % 64; bool is_valid = validity_mask[entry_idx] & (1 « idx_in_entry);

Alternatively, the (slower) duckdb_validity_row_is_valid function can be used.

Syntax

```
            uint64_t *duckdb_vector_get_validity(
  duckdb_vector vector
);
```

Parameters

- `vector`: The vector to get the data from

Return Value The pointer to the validity mask, or NULL if no validity mask is present

`duckdb_vector_ensure_validity_writable` Ensures the validity mask is writable by allocating it.

After this function is called, `duckdb_vector_get_validity` will ALWAYS return non-NULL. This allows NULL values to be written to the vector, regardless of whether a validity mask was present before.

Syntax

```
            void duckdb_vector_ensure_validity_writable(
  duckdb_vector vector
);
```

Parameters

- `vector`: The vector to alter

`duckdb_vector_assign_string_element` Assigns a string element in the vector at the specified location.

Syntax

```
            void duckdb_vector_assign_string_element(
  duckdb_vector vector,
  idx_t index,
  const char *str
);
```

Parameters

- `vector`: The vector to alter
- `index`: The row position in the vector to assign the string to
- `str`: The null-terminated string

`duckdb_vector_assign_string_element_len` Assigns a string element in the vector at the specified location. You may also use this function to assign BLOBs.

Syntax

```
            void duckdb_vector_assign_string_element_len(
  duckdb_vector vector,
  idx_t index,
  const char *str,
  idx_t str_len
);
```

Parameters

- `vector`: The vector to alter
- `index`: The row position in the vector to assign the string to
- `str`: The string
- `str_len`: The length of the string (in bytes)

`duckdb_list_vector_get_child` Retrieves the child vector of a list vector.

The resulting vector is valid as long as the parent vector is valid.

Syntax

```
            duckdb_vector duckdb_list_vector_get_child(
  duckdb_vector vector
);
```

Parameters

- `vector`: The vector

Return Value The child vector

`duckdb_list_vector_get_size` Returns the size of the child vector of the list.

Syntax

```
            idx_t duckdb_list_vector_get_size(
  duckdb_vector vector
);
```

Parameters

- `vector`: The vector

Return Value The size of the child list

`duckdb_list_vector_set_size` Sets the total size of the underlying child-vector of a list vector.

Syntax

```
            duckdb_state duckdb_list_vector_set_size(
  duckdb_vector vector,
  idx_t size
);
```

Parameters

- `vector`: The list vector.
- `size`: The size of the child list.

Return Value The duckdb state. Returns DuckDBError if the vector is nullptr.

`duckdb_list_vector_reserve` Sets the total capacity of the underlying child-vector of a list.

After calling this method, you must call `duckdb_vector_get_validity` and `duckdb_vector_get_data` to obtain current data and validity pointers

Syntax

```
            duckdb_state duckdb_list_vector_reserve(
  duckdb_vector vector,
  idx_t required_capacity
);
```

Parameters

- `vector`: The list vector.
- `required_capacity`: the total capacity to reserve.

Return Value The duckdb state. Returns DuckDBError if the vector is nullptr.

`duckdb_struct_vector_get_child` Retrieves the child vector of a struct vector. The resulting vector is valid as long as the parent vector is valid.

Syntax

```
            duckdb_vector duckdb_struct_vector_get_child(
  duckdb_vector vector,
  idx_t index
);
```

Parameters

- `vector`: The vector
- `index`: The child index

Return Value The child vector

`duckdb_array_vector_get_child` Retrieves the child vector of an array vector. The resulting vector is valid as long as the parent vector is valid. The resulting vector has the size of the parent vector multiplied by the array size.

Syntax

```
            duckdb_vector duckdb_array_vector_get_child(
  duckdb_vector vector
);
```

Parameters

- `vector`: The vector

Return Value The child vector

`duckdb_slice_vector` Slice a vector with a selection vector. The length of the selection vector must be less than or equal to the length of the vector. Turns the vector into a dictionary vector.

Syntax

```
            void duckdb_slice_vector(
  duckdb_vector vector,
  duckdb_selection_vector sel,
  idx_t len
);
```

Parameters

- `vector`: The vector to slice.
- `sel`: The selection vector.
- `len`: The length of the selection vector.

`duckdb_vector_copy_sel` Copy the src vector to the dst with a selection vector that identifies which indices to copy.

Syntax

```
            void duckdb_vector_copy_sel(
  duckdb_vector src,
  duckdb_vector dst,
  duckdb_selection_vector sel,
  idx_t src_count,
  idx_t src_offset,
  idx_t dst_offset
);
```

Parameters

- `src`: The vector to copy from.
- `dst`: The vector to copy to.
- `sel`: The selection vector. The length of the selection vector should not be more than the length of the src vector
- `src_count`: The number of entries from selection vector to copy. Think of this as the effective length of the selection vector starting from index 0
- `src_offset`: The offset in the selection vector to copy from (important: actual number of items copied = src_count - src_offset).
- `dst_offset`: The offset in the dst vector to start copying to.

`duckdb_vector_reference_value` Copies the value from `value` to `vector`.

Syntax

```
            void duckdb_vector_reference_value(
  duckdb_vector vector,
  duckdb_value value
);
```

Parameters

- `vector`: The receiving vector.
- `value`: The value to copy into the vector.

`duckdb_vector_reference_vector` Changes `to_vector` to reference ‘from_vector. After, the vectors share ownership of the data.

Syntax

```
            void duckdb_vector_reference_vector(
  duckdb_vector to_vector,
  duckdb_vector from_vector
);
```

Parameters

- `to_vector`: The receiving vector.
- `from_vector`: The vector to reference.

`duckdb_validity_row_is_valid`

Returns whether or not a row is valid (i.e., not NULL) in the given validity mask.

Syntax

```
            bool duckdb_validity_row_is_valid(
  uint64_t *validity,
  idx_t row
);
```

Parameters

- `validity`: The validity mask, as obtained through `duckdb_vector_get_validity`
- `row`: The row index

Return Value

true if the row is valid, false otherwise

`duckdb_validity_set_row_validity`

In a validity mask, sets a specific row to either valid or invalid.

Note that `duckdb_vector_ensure_validity_writable` should be called before calling `duckdb_vector_get_validity`, to ensure that there is a validity mask to write to.

Syntax

```
            void duckdb_validity_set_row_validity(
  uint64_t *validity,
  idx_t row,
  bool valid
);
```

Parameters

- `validity`: The validity mask, as obtained through `duckdb_vector_get_validity`.
- `row`: The row index
- `valid`: Whether or not to set the row to valid, or invalid

`duckdb_validity_set_row_invalid`

In a validity mask, sets a specific row to invalid.

Equivalent to `duckdb_validity_set_row_validity` with valid set to false.

Syntax

```
            void duckdb_validity_set_row_invalid(
  uint64_t *validity,
  idx_t row
);
```

Parameters

- `validity`: The validity mask
- `row`: The row index

`duckdb_validity_set_row_valid` In a validity mask, sets a specific row to valid.

Equivalent to `duckdb_validity_set_row_validity` with valid set to true.

Syntax

```
            void duckdb_validity_set_row_valid(
  uint64_t *validity,
  idx_t row
);
```

Parameters

- `validity`: The validity mask
- `row`: The row index

`duckdb_create_scalar_function` Creates a new empty scalar function.

The return value must be destroyed with `duckdb_destroy_scalar_function`.

Return Value The scalar function object.

Syntax

```
            duckdb_scalar_function duckdb_create_scalar_function(

);
```

`duckdb_destroy_scalar_function` Destroys the given scalar function object.

Syntax

```
            void duckdb_destroy_scalar_function(
  duckdb_scalar_function *scalar_function
);
```

Parameters

- `scalar_function`: The scalar function to destroy

`duckdb_scalar_function_set_name` Sets the name of the given scalar function.

Syntax

```
            void duckdb_scalar_function_set_name(
  duckdb_scalar_function scalar_function,
  const char *name
);
```

Parameters

- `scalar_function`: The scalar function
- `name`: The name of the scalar function

`duckdb_scalar_function_set_varargs` Sets the parameters of the given scalar function to varargs. Does not require adding parameters with duckdb_scalar_function_add_parameter.

Syntax

```
            void duckdb_scalar_function_set_varargs(
  duckdb_scalar_function scalar_function,
  duckdb_logical_type type
);
```

Parameters

- `scalar_function`: The scalar function.
- `type`: The type of the arguments.

Return Value The parameter type. Cannot contain INVALID.

`duckdb_scalar_function_set_special_handling` Sets the scalar function's null-handling behavior to special.

Syntax

```
            void duckdb_scalar_function_set_special_handling(
  duckdb_scalar_function scalar_function
);
```

Parameters

- `scalar_function`: The scalar function.

`duckdb_scalar_function_set_volatile` Sets the Function Stability of the scalar function to VOLATILE, indicating the function should be re-run for every row. This limits optimization that can be performed for the function.

Syntax

```
            void duckdb_scalar_function_set_volatile(
  duckdb_scalar_function scalar_function
);
```

Parameters

- `scalar_function`: The scalar function.

`duckdb_scalar_function_add_parameter` Adds a parameter to the scalar function.

Syntax

```
            void duckdb_scalar_function_add_parameter(
  duckdb_scalar_function scalar_function,
  duckdb_logical_type type
);
```

Parameters

- `scalar_function`: The scalar function.
- `type`: The parameter type. Cannot contain INVALID.

`duckdb_scalar_function_set_return_type` Sets the return type of the scalar function.

Syntax

```
            void duckdb_scalar_function_set_return_type(
  duckdb_scalar_function scalar_function,
  duckdb_logical_type type
);
```

Parameters

- `scalar_function`: The scalar function
- `type`: Cannot contain INVALID or ANY.

`duckdb_scalar_function_set_extra_info` Assigns extra information to the scalar function that can be fetched during binding, etc.

Syntax

```
            void duckdb_scalar_function_set_extra_info(
  duckdb_scalar_function scalar_function,
  void *extra_info,
  duckdb_delete_callback_t destroy
);
```

Parameters

- `scalar_function`: The scalar function
- `extra_info`: The extra information
- `destroy`: The callback that will be called to destroy the extra information (if any)

`duckdb_scalar_function_set_bind` Sets the (optional) bind function of the scalar function.

Syntax

```
            void duckdb_scalar_function_set_bind(
  duckdb_scalar_function scalar_function,
  duckdb_scalar_function_bind_t bind
);
```

Parameters

- `scalar_function`: The scalar function.
- `bind`: The bind function.

`duckdb_scalar_function_set_bind_data` Sets the user-provided bind data in the bind object of the scalar function. The bind data object can be retrieved again during execution. In most case, you also need to set the copy-callback of your bind data via duckdb_scalar_function_set_bind_data_copy.

Syntax

```
            void duckdb_scalar_function_set_bind_data(
  duckdb_bind_info info,
  void *bind_data,
  duckdb_delete_callback_t destroy
);
```

Parameters

- `info`: The bind info of the scalar function.
- `bind_data`: The bind data object.
- `destroy`: The callback to destroy the bind data (if any).

`duckdb_scalar_function_set_bind_data_copy` Sets the copy-callback for the user-provided bind data in the bind object of the scalar function.

Syntax

```
            void duckdb_scalar_function_set_bind_data_copy(
  duckdb_bind_info info,
  duckdb_copy_callback_t copy
);
```

Parameters

- `info`: The bind info of the scalar function.
- `copy`: The callback to copy the bind data (if any).

`duckdb_scalar_function_bind_set_error` Report that an error has occurred while calling bind on a scalar function.

Syntax

```
            void duckdb_scalar_function_bind_set_error(
  duckdb_bind_info info,
  const char *error
);
```

Parameters

- `info`: The bind info object.
- `error`: The error message.

`duckdb_scalar_function_set_function` Sets the main function of the scalar function.

Syntax

```
            void duckdb_scalar_function_set_function(
  duckdb_scalar_function scalar_function,
  duckdb_scalar_function_t function
);
```

Parameters

- `scalar_function`: The scalar function
- `function`: The function

`duckdb_register_scalar_function` Register the scalar function object within the given connection.

The function requires at least a name, a function and a return type.

If the function is incomplete or a function with this name already exists DuckDBError is returned.

Syntax

```
            duckdb_state duckdb_register_scalar_function(
  duckdb_connection con,
  duckdb_scalar_function scalar_function
);
```

Parameters

- `con`: The connection to register it in.
- `scalar_function`: The function pointer

Return Value Whether or not the registration was successful.

`duckdb_scalar_function_get_extra_info` Retrieves the extra info of the function as set in `duckdb_scalar_function_set_extra_info`.

Syntax

```
            void *duckdb_scalar_function_get_extra_info(
  duckdb_function_info info
);
```

Parameters

- `info`: The info object.

Return Value The extra info.

`duckdb_scalar_function_bind_get_extra_info` Retrieves the extra info of the function as set in the bind info.

Syntax

```
            void *duckdb_scalar_function_bind_get_extra_info(
  duckdb_bind_info info
);
```

Parameters

- `info`: The info object.

Return Value The extra info.

`duckdb_scalar_function_get_bind_data` Gets the scalar function's bind data set by `duckdb_scalar_function_set_bind_data`. Note that the bind data is read-only.

Syntax

```
            void *duckdb_scalar_function_get_bind_data(
  duckdb_function_info info
);
```

Parameters

- `info`: The function info.

Return Value The bind data object.

`duckdb_scalar_function_get_client_context` Retrieves the client context of the bind info of a scalar function.

Syntax

```
            void duckdb_scalar_function_get_client_context(
  duckdb_bind_info info,
  duckdb_client_context *out_context
);
```

Parameters

- `info`: The bind info object of the scalar function.
- `out_context`: The client context of the bind info. Must be destroyed with `duckdb_destroy_client_context`.

`duckdb_scalar_function_set_error` Report that an error has occurred while executing the scalar function.

Syntax

```
            void duckdb_scalar_function_set_error(
  duckdb_function_info info,
  const char *error
);
```

Parameters

- `info`: The info object.
- `error`: The error message

`duckdb_create_scalar_function_set` Creates a new empty scalar function set.

The return value must be destroyed with `duckdb_destroy_scalar_function_set`.

Return Value The scalar function set object.

Syntax

```
            duckdb_scalar_function_set duckdb_create_scalar_function_set(
  const char *name
);
```

`duckdb_destroy_scalar_function_set` Destroys the given scalar function set object.

Syntax

```
            void duckdb_destroy_scalar_function_set(
  duckdb_scalar_function_set *scalar_function_set
);
```

`duckdb_add_scalar_function_to_set` Adds the scalar function as a new overload to the scalar function set.

Returns DuckDBError if the function could not be added, for example if the overload already exists.

Syntax

```
            duckdb_state duckdb_add_scalar_function_to_set(
  duckdb_scalar_function_set set,
  duckdb_scalar_function function
);
```

Parameters

- `set`: The scalar function set
- `function`: The function to add

`duckdb_register_scalar_function_set` Register the scalar function set within the given connection.

The set requires at least a single valid overload.

If the set is incomplete or a function with this name already exists DuckDBError is returned.

Syntax

```
            duckdb_state duckdb_register_scalar_function_set(
  duckdb_connection con,
  duckdb_scalar_function_set set
);
```

Parameters

- `con`: The connection to register it in.
- `set`: The function set to register

Return Value Whether or not the registration was successful.

`duckdb_scalar_function_bind_get_argument_count` Returns the number of input arguments of the scalar function.

Syntax

```
            idx_t duckdb_scalar_function_bind_get_argument_count(
  duckdb_bind_info info
);
```

Parameters

- `info`: The bind info.

Return Value The number of input arguments.

`duckdb_scalar_function_bind_get_argument` Returns the input argument at index of the scalar function.

Syntax

```
            duckdb_expression duckdb_scalar_function_bind_get_argument(
  duckdb_bind_info info,
  idx_t index
);
```

Parameters

- `info`: The bind info.
- `index`: The argument index.

Return Value The input argument at index. Must be destroyed with `duckdb_destroy_expression`.

`duckdb_create_selection_vector` Creates a new selection vector of size `size`. Must be destroyed with `duckdb_destroy_selection_vector`.

Syntax

```
            duckdb_selection_vector duckdb_create_selection_vector(
  idx_t size
);
```

Parameters

- `size`: The size of the selection vector.

Return Value The selection vector.

`duckdb_destroy_selection_vector` Destroys the selection vector and de-allocates its memory.

Syntax

```
            void duckdb_destroy_selection_vector(
  duckdb_selection_vector sel
);
```

Parameters

- `sel`: The selection vector.

`duckdb_selection_vector_get_data_ptr` Access the data pointer of a selection vector.

Syntax

```
            sel_t *duckdb_selection_vector_get_data_ptr(
  duckdb_selection_vector sel
);
```

Parameters

- `sel`: The selection vector.

Return Value The data pointer.

`duckdb_create_aggregate_function` Creates a new empty aggregate function.

The return value should be destroyed with `duckdb_destroy_aggregate_function`.

Return Value The aggregate function object.

Syntax

```
duckdb_aggregate_function duckdb_create_aggregate_function(

);
```

`duckdb_destroy_aggregate_function` Destroys the given aggregate function object.

Syntax

```
void duckdb_destroy_aggregate_function(
  duckdb_aggregate_function *aggregate_function
);
```

`duckdb_aggregate_function_set_name` Sets the name of the given aggregate function.

Syntax

```
void duckdb_aggregate_function_set_name(
  duckdb_aggregate_function aggregate_function,
  const char *name
);
```

Parameters

- `aggregate_function`: The aggregate function
- `name`: The name of the aggregate function

`duckdb_aggregate_function_add_parameter` Adds a parameter to the aggregate function.

Syntax

```
void duckdb_aggregate_function_add_parameter(
  duckdb_aggregate_function aggregate_function,
  duckdb_logical_type type
);
```

Parameters

- `aggregate_function`: The aggregate function.
- `type`: The parameter type. Cannot contain INVALID.

`duckdb_aggregate_function_set_return_type` Sets the return type of the aggregate function.

Syntax

```
            void duckdb_aggregate_function_set_return_type(
  duckdb_aggregate_function aggregate_function,
  duckdb_logical_type type
);
```

Parameters

- `aggregate_function`: The aggregate function.
- `type`: The return type. Cannot contain INVALID or ANY.

`duckdb_aggregate_function_set_functions` Sets the main functions of the aggregate function.

Syntax

```
            void duckdb_aggregate_function_set_functions(
  duckdb_aggregate_function aggregate_function,
  duckdb_aggregate_state_size state_size,
  duckdb_aggregate_init_t state_init,
  duckdb_aggregate_update_t update,
  duckdb_aggregate_combine_t combine,
  duckdb_aggregate_finalize_t finalize
);
```

Parameters

- `aggregate_function`: The aggregate function
- `state_size`: state size
- `state_init`: state init function
- `update`: update states
- `combine`: combine states
- `finalize`: finalize states

`duckdb_aggregate_function_set_destructor` Sets the state destructor callback of the aggregate function (optional)

Syntax

```
            void duckdb_aggregate_function_set_destructor(
  duckdb_aggregate_function aggregate_function,
  duckdb_aggregate_destroy_t destroy
);
```

Parameters

- `aggregate_function`: The aggregate function
- `destroy`: state destroy callback

`duckdb_register_aggregate_function` Register the aggregate function object within the given connection.

The function requires at least a name, functions and a return type.

If the function is incomplete or a function with this name already exists DuckDBError is returned.

Syntax

```
            duckdb_state duckdb_register_aggregate_function(
  duckdb_connection con,
  duckdb_aggregate_function aggregate_function
);
```

Parameters

- `con`: The connection to register it in.

Return Value Whether or not the registration was successful.

`duckdb_aggregate_function_set_special_handling` Sets the NULL handling of the aggregate function to SPECIAL_HANDLING.

Syntax

```
            void duckdb_aggregate_function_set_special_handling(
  duckdb_aggregate_function aggregate_function
);
```

Parameters

- `aggregate_function`: The aggregate function

`duckdb_aggregate_function_set_extra_info` Assigns extra information to the scalar function that can be fetched during binding, etc.

Syntax

```
            void duckdb_aggregate_function_set_extra_info(
  duckdb_aggregate_function aggregate_function,
  void *extra_info,
  duckdb_delete_callback_t destroy
);
```

Parameters

- `aggregate_function`: The aggregate function
- `extra_info`: The extra information
- `destroy`: The callback that will be called to destroy the extra information (if any)

`duckdb_aggregate_function_get_extra_info` Retrieves the extra info of the function as set in `duckdb_aggregate_function_set_extra_info`.

Syntax

```
            void *duckdb_aggregate_function_get_extra_info(
  duckdb_function_info info
);
```

Parameters

- `info`: The info object

Return Value

The extra info

`duckdb_aggregate_function_set_error`

Report that an error has occurred while executing the aggregate function.

Syntax

```
            void duckdb_aggregate_function_set_error(
  duckdb_function_info info,
  const char *error
);
```

Parameters

- `info`: The info object
- `error`: The error message

`duckdb_create_aggregate_function_set`

Creates a new empty aggregate function set.

The return value should be destroyed with `duckdb_destroy_aggregate_function_set`.

Return Value

The aggregate function set object.

Syntax

```
            duckdb_aggregate_function_set duckdb_create_aggregate_function_set(
  const char *name
);
```

`duckdb_destroy_aggregate_function_set`

Destroys the given aggregate function set object.

Syntax

```
            void duckdb_destroy_aggregate_function_set(
  duckdb_aggregate_function_set *aggregate_function_set
);
```

`duckdb_add_aggregate_function_to_set`

Adds the aggregate function as a new overload to the aggregate function set.

Returns DuckDBError if the function could not be added, for example if the overload already exists.

Syntax

```
            duckdb_state duckdb_add_aggregate_function_to_set(
  duckdb_aggregate_function_set set,
  duckdb_aggregate_function function
);
```

Parameters

- `set`: The aggregate function set
- `function`: The function to add

`duckdb_register_aggregate_function_set` Register the aggregate function set within the given connection.

The set requires at least a single valid overload.

If the set is incomplete or a function with this name already exists DuckDBError is returned.

Syntax

```
            duckdb_state duckdb_register_aggregate_function_set(
  duckdb_connection con,
  duckdb_aggregate_function_set set
);
```

Parameters

- `con`: The connection to register it in.
- `set`: The function set to register

Return Value Whether or not the registration was successful.

`duckdb_create_table_function` Creates a new empty table function.

The return value should be destroyed with `duckdb_destroy_table_function`.

Return Value The table function object.

Syntax

```
            duckdb_table_function duckdb_create_table_function(

);
```

`duckdb_destroy_table_function` Destroys the given table function object.

Syntax

```
            void duckdb_destroy_table_function(
  duckdb_table_function *table_function
);
```

Parameters

- `table_function`: The table function to destroy

`duckdb_table_function_set_name` Sets the name of the given table function.

Syntax

```
            void duckdb_table_function_set_name(
  duckdb_table_function table_function,
  const char *name
);
```

Parameters

- `table_function`: The table function
- `name`: The name of the table function

`duckdb_table_function_add_parameter` Adds a parameter to the table function.

Syntax

```
            void duckdb_table_function_add_parameter(
  duckdb_table_function table_function,
  duckdb_logical_type type
);
```

Parameters

- `table_function`: The table function.
- `type`: The parameter type. Cannot contain INVALID.

`duckdb_table_function_add_named_parameter` Adds a named parameter to the table function.

Syntax

```
            void duckdb_table_function_add_named_parameter(
  duckdb_table_function table_function,
  const char *name,
  duckdb_logical_type type
);
```

Parameters

- `table_function`: The table function.
- `name`: The parameter name.
- `type`: The parameter type. Cannot contain INVALID.

`duckdb_table_function_set_extra_info` Assigns extra information to the table function that can be fetched during binding, etc.

Syntax

```
            void duckdb_table_function_set_extra_info(
  duckdb_table_function table_function,
  void *extra_info,
  duckdb_delete_callback_t destroy
);
```

Parameters

- `table_function`: The table function
- `extra_info`: The extra information
- `destroy`: The callback that will be called to destroy the extra information (if any)

`duckdb_table_function_set_bind` Sets the bind function of the table function.

Syntax

```
            void duckdb_table_function_set_bind(
  duckdb_table_function table_function,
  duckdb_table_function_bind_t bind
);
```

Parameters

- `table_function`: The table function
- `bind`: The bind function

`duckdb_table_function_set_init` Sets the init function of the table function.

Syntax

```
            void duckdb_table_function_set_init(
  duckdb_table_function table_function,
  duckdb_table_function_init_t init
);
```

Parameters

- `table_function`: The table function
- `init`: The init function

`duckdb_table_function_set_local_init` Sets the thread-local init function of the table function.

Syntax

```
            void duckdb_table_function_set_local_init(
  duckdb_table_function table_function,
  duckdb_table_function_init_t init
);
```

Parameters

- `table_function`: The table function
- `init`: The init function

`duckdb_table_function_set_function` Sets the main function of the table function.

Syntax

```
            void duckdb_table_function_set_function(
  duckdb_table_function table_function,
  duckdb_table_function_t function
);
```

Parameters

- `table_function`: The table function
- `function`: The function

`duckdb_table_function_supports_projection_pushdown` Sets whether or not the given table function supports projection pushdown.

If this is set to true, the system will provide a list of all required columns in the `init` stage through the `duckdb_init_get_column_count` and `duckdb_init_get_column_index` functions. If this is set to false (the default), the system will expect all columns to be projected.

Syntax

```
            void duckdb_table_function_supports_projection_pushdown(
  duckdb_table_function table_function,
  bool pushdown
);
```

Parameters

- `table_function`: The table function
- `pushdown`: True if the table function supports projection pushdown, false otherwise.

`duckdb_register_table_function` Register the table function object within the given connection.

The function requires at least a name, a bind function, an init function and a main function.

If the function is incomplete or a function with this name already exists DuckDBError is returned.

Syntax

```
            duckdb_state duckdb_register_table_function(
  duckdb_connection con,
  duckdb_table_function function
);
```

Parameters

- `con`: The connection to register it in.
- `function`: The function pointer

Return Value Whether or not the registration was successful.

`duckdb_bind_get_extra_info` Retrieves the extra info of the function as set in `duckdb_table_function_set_extra_info`.

Syntax

```
            void *duckdb_bind_get_extra_info(
  duckdb_bind_info info
);
```

Parameters

- `info`: The info object

Return Value The extra info

`duckdb_table_function_get_client_context` Retrieves the client context of the bind info of a table function.

Syntax

```
            void duckdb_table_function_get_client_context(
  duckdb_bind_info info,
  duckdb_client_context *out_context
);
```

Parameters

- `info`: The bind info object of the table function.
- `out_context`: The client context of the bind info. Must be destroyed with `duckdb_destroy_client_context`.

`duckdb_bind_add_result_column` Adds a result column to the output of the table function.

Syntax

```
            void duckdb_bind_add_result_column(
  duckdb_bind_info info,
  const char *name,
  duckdb_logical_type type
);
```

Parameters

- `info`: The table function's bind info.
- `name`: The column name.
- `type`: The logical column type.

`duckdb_bind_get_parameter_count` Retrieves the number of regular (non-named) parameters to the function.

Syntax

```
            idx_t duckdb_bind_get_parameter_count(
  duckdb_bind_info info
);
```

Parameters

- `info`: The info object

Return Value The number of parameters

`duckdb_bind_get_parameter` Retrieves the parameter at the given index.

The result must be destroyed with `duckdb_destroy_value`.

Syntax

```
            duckdb_value duckdb_bind_get_parameter(
  duckdb_bind_info info,
  idx_t index
);
```

Parameters

- `info`: The info object
- `index`: The index of the parameter to get

Return Value The value of the parameter. Must be destroyed with `duckdb_destroy_value`.

`duckdb_bind_get_named_parameter` Retrieves a named parameter with the given name.

The result must be destroyed with `duckdb_destroy_value`.

Syntax

```
            duckdb_value duckdb_bind_get_named_parameter(
  duckdb_bind_info info,
  const char *name
);
```

Parameters

- `info`: The info object
- `name`: The name of the parameter

Return Value The value of the parameter. Must be destroyed with `duckdb_destroy_value`.

`duckdb_bind_set_bind_data` Sets the user-provided bind data in the bind object of the table function. This object can be retrieved again during execution.

Syntax

```
            void duckdb_bind_set_bind_data(
  duckdb_bind_info info,
  void *bind_data,
  duckdb_delete_callback_t destroy
);
```

Parameters

- `info`: The bind info of the table function.
- `bind_data`: The bind data object.
- `destroy`: The callback to destroy the bind data (if any).

`duckdb_bind_set_cardinality` Sets the cardinality estimate for the table function, used for optimization.

Syntax

```
            void duckdb_bind_set_cardinality(
  duckdb_bind_info info,
  idx_t cardinality,
  bool is_exact
);
```

Parameters

- `info`: The bind data object.
- `is_exact`: Whether or not the cardinality estimate is exact, or an approximation

`duckdb_bind_set_error` Report that an error has occurred while calling bind on a table function.

Syntax

```
            void duckdb_bind_set_error(
  duckdb_bind_info info,
  const char *error
);
```

Parameters

- `info`: The info object
- `error`: The error message

`duckdb_init_get_extra_info` Retrieves the extra info of the function as set in `duckdb_table_function_set_extra_info`.

Syntax

```
            void *duckdb_init_get_extra_info(
  duckdb_init_info info
);
```

Parameters

- `info`: The info object

Return Value The extra info

`duckdb_init_get_bind_data` Gets the bind data set by `duckdb_bind_set_bind_data` during the bind.

Note that the bind data should be considered as read-only. For tracking state, use the init data instead.

Syntax

```
            void *duckdb_init_get_bind_data(
  duckdb_init_info info
);
```

Parameters

- `info`: The info object

Return Value

The bind data object

`duckdb_init_set_init_data` Sets the user-provided init data in the init object. This object can be retrieved again during execution.

Syntax

```
            void duckdb_init_set_init_data(
  duckdb_init_info info,
  void *init_data,
  duckdb_delete_callback_t destroy
);
```

Parameters

- `info`: The info object
- `init_data`: The init data object.
- `destroy`: The callback that will be called to destroy the init data (if any)

`duckdb_init_get_column_count` Returns the number of projected columns.

This function must be used if projection pushdown is enabled to figure out which columns to emit.

Syntax

```
            idx_t duckdb_init_get_column_count(
  duckdb_init_info info
);
```

Parameters

- `info`: The info object

Return Value

The number of projected columns.

`duckdb_init_get_column_index` Returns the column index of the projected column at the specified position.

This function must be used if projection pushdown is enabled to figure out which columns to emit.

Syntax

```
            idx_t duckdb_init_get_column_index(
  duckdb_init_info info,
  idx_t column_index
);
```

Parameters

- `info`: The info object
- `column_index`: The index at which to get the projected column index, from 0..duckdb_init_get_column_count(info)

Return Value The column index of the projected column.

`duckdb_init_set_max_threads` Sets how many threads can process this table function in parallel (default: 1)

Syntax

```
            void duckdb_init_set_max_threads(
  duckdb_init_info info,
  idx_t max_threads
);
```

Parameters

- `info`: The info object
- `max_threads`: The maximum amount of threads that can process this table function

`duckdb_init_set_error` Report that an error has occurred while calling init.

Syntax

```
            void duckdb_init_set_error(
  duckdb_init_info info,
  const char *error
);
```

Parameters

- `info`: The info object
- `error`: The error message

`duckdb_function_get_extra_info` Retrieves the extra info of the function as set in `duckdb_table_function_set_extra_info`.

Syntax

```
            void *duckdb_function_get_extra_info(
  duckdb_function_info info
);
```

Parameters

- `info`: The info object

Return Value The extra info

`duckdb_function_get_bind_data` Gets the table function's bind data set by `duckdb_bind_set_bind_data`.

Note that the bind data is read-only. For tracking state, use the init data instead.

Syntax

```
            void *duckdb_function_get_bind_data(
  duckdb_function_info info
);
```

Parameters

- `info`: The function info object.

Return Value

The bind data object.

`duckdb_function_get_init_data`

Gets the init data set by `duckdb_init_set_init_data` during the init.

Syntax

```
            void *duckdb_function_get_init_data(
  duckdb_function_info info
);
```

Parameters

- `info`: The info object

Return Value

The init data object

`duckdb_function_get_local_init_data`

Gets the thread-local init data set by `duckdb_init_set_init_data` during the local_init.

Syntax

```
            void *duckdb_function_get_local_init_data(
  duckdb_function_info info
);
```

Parameters

- `info`: The info object

Return Value

The init data object

`duckdb_function_set_error`

Report that an error has occurred while executing the function.

Syntax

```
            void duckdb_function_set_error(
  duckdb_function_info info,
  const char *error
);
```

Parameters

- `info`: The info object
- `error`: The error message

`duckdb_add_replacement_scan`

Add a replacement scan definition to the specified database.

Syntax

```
            void duckdb_add_replacement_scan(
  duckdb_database db,
  duckdb_replacement_callback_t replacement,
  void *extra_data,
  duckdb_delete_callback_t delete_callback
);
```

Parameters

- db: The database object to add the replacement scan to
- `replacement`: The replacement scan callback
- `extra_data`: Extra data that is passed back into the specified callback
- `delete_callback`: The delete callback to call on the extra data, if any

`duckdb_replacement_scan_set_function_name` Sets the replacement function name. If this function is called in the replacement callback, the replacement scan is performed. If it is not called, the replacement callback is not performed.

Syntax

```
            void duckdb_replacement_scan_set_function_name(
  duckdb_replacement_scan_info info,
  const char *function_name
);
```

Parameters

- `info`: The info object
- `function_name`: The function name to substitute.

`duckdb_replacement_scan_add_parameter` Adds a parameter to the replacement scan function.

Syntax

```
            void duckdb_replacement_scan_add_parameter(
  duckdb_replacement_scan_info info,
  duckdb_value parameter
);
```

Parameters

- `info`: The info object
- `parameter`: The parameter to add.

`duckdb_replacement_scan_set_error` Report that an error has occurred while executing the replacement scan.

Syntax

```
            void duckdb_replacement_scan_set_error(
  duckdb_replacement_scan_info info,
  const char *error
);
```

Parameters

- `info`: The info object
- `error`: The error message

`duckdb_get_profiling_info` Returns the root node of the profiling information. Returns nullptr, if profiling is not enabled.

Syntax

```
            duckdb_profiling_info duckdb_get_profiling_info(
  duckdb_connection connection
);
```

Parameters

- `connection`: A connection object.

Return Value A profiling information object.

`duckdb_profiling_info_get_value` Returns the value of the metric of the current profiling info node. Returns nullptr, if the metric does not exist or is not enabled. Currently, the value holds a string, and you can retrieve the string by calling the corresponding function: char *duckdb_get_varchar(duckdb_value value).

Syntax

```
            duckdb_value duckdb_profiling_info_get_value(
  duckdb_profiling_info info,
  const char *key
);
```

Parameters

- `info`: A profiling information object.
- `key`: The name of the requested metric.

Return Value The value of the metric. Must be freed with `duckdb_destroy_value`

`duckdb_profiling_info_get_metrics` Returns the key-value metric map of this profiling node as a MAP duckdb_value. The individual elements are accessible via the duckdb_value MAP functions.

Syntax

```
            duckdb_value duckdb_profiling_info_get_metrics(
  duckdb_profiling_info info
);
```

Parameters

- `info`: A profiling information object.

Return Value The key-value metric map as a MAP duckdb_value.

`duckdb_profiling_info_get_child_count` Returns the number of children in the current profiling info node.

Syntax

```
            idx_t duckdb_profiling_info_get_child_count(
  duckdb_profiling_info info
);
```

Parameters

- `info`: A profiling information object.

Return Value The number of children in the current node.

`duckdb_profiling_info_get_child` Returns the child node at the specified index.

Syntax

```
            duckdb_profiling_info duckdb_profiling_info_get_child(
  duckdb_profiling_info info,
  idx_t index
);
```

Parameters

- `info`: A profiling information object.
- `index`: The index of the child node.

Return Value The child node at the specified index.

`duckdb_appender_create` Creates an appender object.

Note that the object must be destroyed with `duckdb_appender_destroy`.

Syntax

```
            duckdb_state duckdb_appender_create(
  duckdb_connection connection,
  const char *schema,
  const char *table,
  duckdb_appender *out_appender
);
```

Parameters

- `connection`: The connection context to create the appender in.
- `schema`: The schema of the table to append to, or `nullptr` for the default schema.
- `table`: The table name to append to.
- `out_appender`: The resulting appender object.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_appender_create_ext` Creates an appender object.

Note that the object must be destroyed with `duckdb_appender_destroy`.

Syntax

```
            duckdb_state duckdb_appender_create_ext(
  duckdb_connection connection,
  const char *catalog,
  const char *schema,
  const char *table,
  duckdb_appender *out_appender
);
```

Parameters

- `connection`: The connection context to create the appender in.
- `catalog`: The catalog of the table to append to, or `nullptr` for the default catalog.
- `schema`: The schema of the table to append to, or `nullptr` for the default schema.
- `table`: The table name to append to.
- `out_appender`: The resulting appender object.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_appender_create_query` Creates an appender object that executes the given query with any data appended to it.

Note that the object must be destroyed with `duckdb_appender_destroy`.

Syntax

```
            duckdb_state duckdb_appender_create_query(
  duckdb_connection connection,
  const char *query,
  idx_t column_count,
  duckdb_logical_type *types,
  const char *table_name,
  const char **column_names,
  duckdb_appender *out_appender
);
```

Parameters

- `connection`: The connection context to create the appender in.
- `query`: The query to execute, can be an INSERT, DELETE, UPDATE or MERGE INTO statement.
- `column_count`: The number of columns to append.
- `types`: The types of the columns to append.
- `table_name`: (optionally) the table name used to refer to the appended data, defaults to "appended_data".
- `column_names`: (optionally) the list of column names, defaults to "col1", "col2", ...
- `out_appender`: The resulting appender object.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_appender_column_count` Returns the number of columns that belong to the appender. If there is no active column list, then this equals the table's physical columns.

Syntax

```
            idx_t duckdb_appender_column_count(
  duckdb_appender appender
);
```

Parameters

- `appender`: The appender to get the column count from.

Return Value The number of columns in the data chunks.

`duckdb_appender_column_type` Returns the type of the column at the specified index. This is either a type in the active column list, or the same type as a column in the receiving table.

Note: The resulting type must be destroyed with `duckdb_destroy_logical_type`.

Syntax

```
            duckdb_logical_type duckdb_appender_column_type(
  duckdb_appender appender,
  idx_t col_idx
);
```

Parameters

- `appender`: The appender to get the column type from.
- `col_idx`: The index of the column to get the type of.

Return Value The `duckdb_logical_type` of the column.

`duckdb_appender_error`

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release. Use duckdb_appender_error_data instead.

Returns the error message associated with the appender. If the appender has no error message, this returns `nullptr` instead.

The error message should not be freed. It will be de-allocated when `duckdb_appender_destroy` is called.

Syntax

```
            const char *duckdb_appender_error(
  duckdb_appender appender
);
```

Parameters

- `appender`: The appender to get the error from.

Return Value The error message, or `nullptr` if there is none.

`duckdb_appender_error_data` Returns the error data associated with the appender. Must be destroyed with duckdb_destroy_error_data.

Syntax

```
            duckdb_error_data duckdb_appender_error_data(
  duckdb_appender appender
);
```

Parameters

- `appender`: The appender to get the error data from.

Return Value The error data.

`duckdb_appender_flush` Flush the appender to the table, forcing the cache of the appender to be cleared. If flushing the data triggers a constraint violation or any other error, then all data is invalidated, and this function returns DuckDBError. It is not possible to append more values. Call duckdb_appender_error_data to obtain the error data followed by duckdb_appender_destroy to destroy the invalidated appender.

Syntax

```
            duckdb_state duckdb_appender_flush(
  duckdb_appender appender
);
```

Parameters

- `appender`: The appender to flush.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_appender_close` Closes the appender by flushing all intermediate states and closing it for further appends. If flushing the data triggers a constraint violation or any other error, then all data is invalidated, and this function returns DuckDBError. Call duckdb_appender_error_data to obtain the error data followed by duckdb_appender_destroy to destroy the invalidated appender.

Syntax

```
            duckdb_state duckdb_appender_close(
  duckdb_appender appender
);
```

Parameters

- `appender`: The appender to flush and close.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_appender_destroy` Closes the appender by flushing all intermediate states to the table and destroying it. By destroying it, this function de-allocates all memory associated with the appender. If flushing the data triggers a constraint violation, then all data is invalidated, and this function returns DuckDBError. Due to the destruction of the appender, it is no longer possible to obtain the specific error message with duckdb_appender_error. Therefore, call duckdb_appender_close before destroying the appender, if you need insights into the specific error.

Syntax

```
            duckdb_state duckdb_appender_destroy(
  duckdb_appender *appender
);
```

Parameters

- `appender`: The appender to flush, close and destroy.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_appender_add_column` Appends a column to the active column list of the appender. Immediately flushes all previous data.

The active column list specifies all columns that are expected when flushing the data. Any non-active columns are filled with their default values, or NULL.

Syntax

```
            duckdb_state duckdb_appender_add_column(
  duckdb_appender appender,
  const char *name
);
```

Parameters

- `appender`: The appender to add the column to.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_appender_clear_columns` Removes all columns from the active column list of the appender, resetting the appender to treat all columns as active. Immediately flushes all previous data.

Syntax

```
            duckdb_state duckdb_appender_clear_columns(
  duckdb_appender appender
);
```

Parameters

- `appender`: The appender to clear the columns from.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_appender_begin_row` A nop function, provided for backwards compatibility reasons. Does nothing. Only `duckdb_appender_end_row` is required.

Syntax

```
            duckdb_state duckdb_appender_begin_row(
  duckdb_appender appender
);
```

`duckdb_appender_end_row` Finish the current row of appends. After end_row is called, the next row can be appended.

Syntax

```
            duckdb_state duckdb_appender_end_row(
  duckdb_appender appender
);
```

Parameters

- `appender`: The appender.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_append_default` Append a DEFAULT value (NULL if DEFAULT not available for column) to the appender.

Syntax

```
            duckdb_state duckdb_append_default(
  duckdb_appender appender
);
```

`duckdb_append_default_to_chunk` Append a DEFAULT value, at the specified row and column, (NULL if DEFAULT not available for column) to the chunk created from the specified appender. The default value of the column must be a constant value. Non-deterministic expressions like nextval('seq') or random() are not supported.

Syntax

```
            duckdb_state duckdb_append_default_to_chunk(
  duckdb_appender appender,
  duckdb_data_chunk chunk,
  idx_t col,
  idx_t row
);
```

Parameters

- `appender`: The appender to get the default value from.
- `chunk`: The data chunk to append the default value to.
- `col`: The chunk column index to append the default value to.
- `row`: The chunk row index to append the default value to.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_append_bool` Append a bool value to the appender.

Syntax

```
            duckdb_state duckdb_append_bool(
  duckdb_appender appender,
  bool value
);
```

duckdb_append_int8 Append an int8_t value to the appender.

Syntax

```
            duckdb_state duckdb_append_int8(
  duckdb_appender appender,
  int8_t value
);
```

duckdb_append_int16 Append an int16_t value to the appender.

Syntax

```
            duckdb_state duckdb_append_int16(
  duckdb_appender appender,
  int16_t value
);
```

duckdb_append_int32 Append an int32_t value to the appender.

Syntax

```
            duckdb_state duckdb_append_int32(
  duckdb_appender appender,
  int32_t value
);
```

duckdb_append_int64 Append an int64_t value to the appender.

Syntax

```
            duckdb_state duckdb_append_int64(
  duckdb_appender appender,
  int64_t value
);
```

duckdb_append_hugeint Append a duckdb_hugeint value to the appender.

Syntax

```
            duckdb_state duckdb_append_hugeint(
  duckdb_appender appender,
  duckdb_hugeint value
);
```

duckdb_append_uint8 Append a uint8_t value to the appender.

Syntax

```
            duckdb_state duckdb_append_uint8(
  duckdb_appender appender,
  uint8_t value
);
```

duckdb_append_uint16 Append a uint16_t value to the appender.

Syntax

```
            duckdb_state duckdb_append_uint16(
  duckdb_appender appender,
  uint16_t value
);
```

duckdb_append_uint32 Append a uint32_t value to the appender.

Syntax

```
            duckdb_state duckdb_append_uint32(
  duckdb_appender appender,
  uint32_t value
);
```

duckdb_append_uint64 Append a uint64_t value to the appender.

Syntax

```
            duckdb_state duckdb_append_uint64(
  duckdb_appender appender,
  uint64_t value
);
```

duckdb_append_uhugeint Append a duckdb_uhugeint value to the appender.

Syntax

```
            duckdb_state duckdb_append_uhugeint(
  duckdb_appender appender,
  duckdb_uhugeint value
);
```

duckdb_append_float Append a float value to the appender.

Syntax

```
            duckdb_state duckdb_append_float(
  duckdb_appender appender,
  float value
);
```

duckdb_append_double Append a double value to the appender.

Syntax

```
            duckdb_state duckdb_append_double(
  duckdb_appender appender,
  double value
);
```

`duckdb_append_date` Append a duckdb_date value to the appender.

Syntax

```
            duckdb_state duckdb_append_date(
  duckdb_appender appender,
  duckdb_date value
);
```

`duckdb_append_time` Append a duckdb_time value to the appender.

Syntax

```
            duckdb_state duckdb_append_time(
  duckdb_appender appender,
  duckdb_time value
);
```

`duckdb_append_timestamp` Append a duckdb_timestamp value to the appender.

Syntax

```
            duckdb_state duckdb_append_timestamp(
  duckdb_appender appender,
  duckdb_timestamp value
);
```

`duckdb_append_interval` Append a duckdb_interval value to the appender.

Syntax

```
            duckdb_state duckdb_append_interval(
  duckdb_appender appender,
  duckdb_interval value
);
```

`duckdb_append_varchar` Append a varchar value to the appender.

Syntax

```
            duckdb_state duckdb_append_varchar(
  duckdb_appender appender,
  const char *val
);
```

`duckdb_append_varchar_length` Append a varchar value to the appender.

Syntax

```
            duckdb_state duckdb_append_varchar_length(
  duckdb_appender appender,
  const char *val,
  idx_t length
);
```

duckdb_append_blob Append a blob value to the appender.

Syntax

```
            duckdb_state duckdb_append_blob(
  duckdb_appender appender,
  const void *data,
  idx_t length
);
```

duckdb_append_null Append a NULL value to the appender (of any type).

Syntax

```
            duckdb_state duckdb_append_null(
  duckdb_appender appender
);
```

duckdb_append_value Append a duckdb_value to the appender.

Syntax

```
            duckdb_state duckdb_append_value(
  duckdb_appender appender,
  duckdb_value value
);
```

duckdb_append_data_chunk Appends a pre-filled data chunk to the specified appender. Attempts casting, if the data chunk types do not match the active appender types.

Syntax

```
            duckdb_state duckdb_append_data_chunk(
  duckdb_appender appender,
  duckdb_data_chunk chunk
);
```

Parameters

- `appender`: The appender to append to.
- `chunk`: The data chunk to append.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

duckdb_table_description_create Creates a table description object. Note that `duckdb_table_description_destroy` should always be called on the resulting table_description, even if the function returns `DuckDBError`.

Syntax

```
            duckdb_state duckdb_table_description_create(
  duckdb_connection connection,
  const char *schema,
  const char *table,
  duckdb_table_description *out
);
```

Parameters

- `connection`: The connection context.
- `schema`: The schema of the table, or `nullptr` for the default schema.
- `table`: The table name.
- `out`: The resulting table description object.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_table_description_create_ext` Creates a table description object. Note that `duckdb_table_description_destroy` must be called on the resulting table_description, even if the function returns `DuckDBError`.

Syntax

```
            duckdb_state duckdb_table_description_create_ext(
  duckdb_connection connection,
  const char *catalog,
  const char *schema,
  const char *table,
  duckdb_table_description *out
);
```

Parameters

- `connection`: The connection context.
- `catalog`: The catalog (database) name of the table, or `nullptr` for the default catalog.
- `schema`: The schema of the table, or `nullptr` for the default schema.
- `table`: The table name.
- `out`: The resulting table description object.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_table_description_destroy` Destroy the TableDescription object.

Syntax

```
            void duckdb_table_description_destroy(
  duckdb_table_description *table_description
);
```

Parameters

- `table_description`: The table_description to destroy.

`duckdb_table_description_error` Returns the error message associated with the given table_description. If the table_description has no error message, this returns `nullptr` instead. The error message should not be freed. It will be de-allocated when `duckdb_table_description_destroy` is called.

Syntax

```
            const char *duckdb_table_description_error(
  duckdb_table_description table_description
);
```

Parameters

- `table_description`: The table_description to get the error from.

Return Value The error message, or `nullptr` if there is none.

`duckdb_column_has_default` Check if the column at 'index' index of the table has a DEFAULT expression.

Syntax

```
            duckdb_state duckdb_column_has_default(
  duckdb_table_description table_description,
  idx_t index,
  bool *out
);
```

Parameters

- `table_description`: The table_description to query.
- `index`: The index of the column to query.
- `out`: The out-parameter used to store the result.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_table_description_get_column_name` Obtain the column name at 'index'. The out result must be destroyed with `duckdb_free`.

Syntax

```
            char *duckdb_table_description_get_column_name(
  duckdb_table_description table_description,
  idx_t index
);
```

Parameters

- `table_description`: The table_description to query.
- `index`: The index of the column to query.

Return Value The column name.

`duckdb_to_arrow_schema` Transforms a DuckDB Schema into an Arrow Schema

Syntax

```
           duckdb_error_data duckdb_to_arrow_schema(
  duckdb_arrow_options arrow_options,
  duckdb_logical_type *types,
  const char **names,
  idx_t column_count,
  struct ArrowSchema *out_schema
);
```

Parameters

- `arrow_options`: The Arrow settings used to produce arrow.
- `types`: The DuckDB logical types for each column in the schema.
- `names`: The names for each column in the schema.
- `column_count`: The number of columns that exist in the schema.
- `out_schema`: The resulting arrow schema. Must be destroyed with `out_schema->release(out_schema)`.

Return Value The error data. Must be destroyed with `duckdb_destroy_error_data`.

`duckdb_data_chunk_to_arrow` Transforms a DuckDB data chunk into an Arrow array.

Syntax

```
           duckdb_error_data duckdb_data_chunk_to_arrow(
  duckdb_arrow_options arrow_options,
  duckdb_data_chunk chunk,
  struct ArrowArray *out_arrow_array
);
```

Parameters

- `arrow_options`: The Arrow settings used to produce arrow.
- `chunk`: The DuckDB data chunk to convert.
- `out_arrow_array`: The output Arrow structure that will hold the converted data. Must be released with `out_arrow_array->release(out_arrow_array)`

Return Value The error data. Must be destroyed with `duckdb_destroy_error_data`.

`duckdb_schema_from_arrow` Transforms an Arrow Schema into a DuckDB Schema.

Syntax

```
           duckdb_error_data duckdb_schema_from_arrow(
  duckdb_connection connection,
  struct ArrowSchema *schema,
  duckdb_arrow_converted_schema *out_types
);
```

Parameters

- `connection`: The connection to get the transformation settings from.
- `schema`: The input Arrow schema. Must be released with `schema->release(schema)`.
- `out_types`: The Arrow converted schema with extra information about the arrow types. Must be destroyed with `duckdb_destroy_arrow_converted_schema`.

Return Value The error data. Must be destroyed with `duckdb_destroy_error_data`.

`duckdb_data_chunk_from_arrow` Transforms an Arrow array into a DuckDB data chunk. The data chunk will retain ownership of the underlying Arrow data.

Syntax

```
            duckdb_error_data duckdb_data_chunk_from_arrow(
  duckdb_connection connection,
  struct ArrowArray *arrow_array,
  duckdb_arrow_converted_schema converted_schema,
  duckdb_data_chunk *out_chunk
);
```

Parameters

- `connection`: The connection to get the transformation settings from.
- `arrow_array`: The input Arrow array. Data ownership is passed on to DuckDB's DataChunk, the underlying object does not need to be released and won't have ownership of the data.
- `converted_schema`: The Arrow converted schema with extra information about the arrow types.
- `out_chunk`: The resulting DuckDB data chunk. Must be destroyed by duckdb_destroy_data_chunk.

Return Value The error data. Must be destroyed with `duckdb_destroy_error_data`.

`duckdb_destroy_arrow_converted_schema` Destroys the arrow converted schema and de-allocates all memory allocated for that arrow converted schema.

Syntax

```
            void duckdb_destroy_arrow_converted_schema(
  duckdb_arrow_converted_schema *arrow_converted_schema
);
```

Parameters

- `arrow_converted_schema`: The arrow converted schema to destroy.

`duckdb_query_arrow`

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Executes a SQL query within a connection and stores the full (materialized) result in an arrow structure. If the query fails to execute, DuckDBError is returned and the error message can be retrieved by calling `duckdb_query_arrow_error`.

Note that after running `duckdb_query_arrow`, `duckdb_destroy_arrow` must be called on the result object even if the query fails, otherwise the error stored within the result will not be freed correctly.

Syntax

```
            duckdb_state duckdb_query_arrow(
  duckdb_connection connection,
  const char *query,
  duckdb_arrow *out_result
);
```

Parameters

- `connection`: The connection to perform the query in.
- `query`: The SQL query to run.
- `out_result`: The query result.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_query_arrow_schema`

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Fetch the internal arrow schema from the arrow result. Remember to call release on the respective ArrowSchema object.

Syntax

```
           duckdb_state duckdb_query_arrow_schema(
  duckdb_arrow result,
  duckdb_arrow_schema *out_schema
);
```

Parameters

- `result`: The result to fetch the schema from.
- `out_schema`: The output schema.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_prepared_arrow_schema`

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Fetch the internal arrow schema from the prepared statement. Remember to call release on the respective ArrowSchema object.

Syntax

```
           duckdb_state duckdb_prepared_arrow_schema(
  duckdb_prepared_statement prepared,
  duckdb_arrow_schema *out_schema
);
```

Parameters

- `prepared`: The prepared statement to fetch the schema from.
- `out_schema`: The output schema.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_result_arrow_array`

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Convert a data chunk into an arrow struct array. Remember to call release on the respective ArrowArray object.

Syntax

```
            void duckdb_result_arrow_array(
  duckdb_result result,
  duckdb_data_chunk chunk,
  duckdb_arrow_array *out_array
);
```

Parameters

- `result`: The result object the data chunk have been fetched from.
- chunk: The data chunk to convert.
- `out_array`: The output array.

`duckdb_query_arrow_array`

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Fetch an internal arrow struct array from the arrow result. Remember to call release on the respective ArrowArray object.

This function can be called multiple time to get next chunks, which will free the previous out_array. So consume the out_array before calling this function again.

Syntax

```
            duckdb_state duckdb_query_arrow_array(
  duckdb_arrow result,
  duckdb_arrow_array *out_array
);
```

Parameters

- `result`: The result to fetch the array from.
- `out_array`: The output array.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_arrow_column_count`

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Returns the number of columns present in the arrow result object.

Syntax

```
            idx_t duckdb_arrow_column_count(
  duckdb_arrow result
);
```

Parameters

- `result`: The result object.

Return Value The number of columns present in the result object.

`duckdb_arrow_row_count`

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Returns the number of rows present in the arrow result object.

Syntax

```
            idx_t duckdb_arrow_row_count(
  duckdb_arrow result
);
```

Parameters

- `result`: The result object.

Return Value The number of rows present in the result object.

`duckdb_arrow_rows_changed`

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Returns the number of rows changed by the query stored in the arrow result. This is relevant only for INSERT/UPDATE/DELETE queries. For other queries the rows_changed will be 0.

Syntax

```
            idx_t duckdb_arrow_rows_changed(
  duckdb_arrow result
);
```

Parameters

- `result`: The result object.

Return Value The number of rows changed.

`duckdb_query_arrow_error`

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Returns the error message contained within the result. The error is only set if `duckdb_query_arrow` returns `DuckDBError`.

The error message should not be freed. It will be de-allocated when `duckdb_destroy_arrow` is called.

Syntax

```
            const char *duckdb_query_arrow_error(
  duckdb_arrow result
);
```

Parameters

- `result`: The result object to fetch the error from.

Return Value The error of the result.

duckdb_destroy_arrow

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Closes the result and de-allocates all memory allocated for the arrow result.

Syntax

```
            void duckdb_destroy_arrow(
  duckdb_arrow *result
);
```

Parameters

- `result`: The result to destroy.

duckdb_destroy_arrow_stream

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Releases the arrow array stream and de-allocates its memory.

Syntax

```
            void duckdb_destroy_arrow_stream(
  duckdb_arrow_stream *stream_p
);
```

Parameters

- `stream_p`: The arrow array stream to destroy.

duckdb_execute_prepared_arrow

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Executes the prepared statement with the given bound parameters, and returns an arrow query result. Note that after running `duckdb_execute_prepared_arrow`, `duckdb_destroy_arrow` must be called on the result object.

Syntax

```
            duckdb_state duckdb_execute_prepared_arrow(
  duckdb_prepared_statement prepared_statement,
  duckdb_arrow *out_result
);
```

Parameters

- `prepared_statement`: The prepared statement to execute.
- `out_result`: The query result.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

duckdb_arrow_scan

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Scans the Arrow stream and creates a view with the given name.

Syntax

```
           duckdb_state duckdb_arrow_scan(
  duckdb_connection connection,
  const char *table_name,
  duckdb_arrow_stream arrow
);
```

Parameters

- `connection`: The connection on which to execute the scan.
- `table_name`: Name of the temporary view to create.
- `arrow`: Arrow stream wrapper.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_arrow_array_scan`

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Scans the Arrow array and creates a view with the given name. Note that after running `duckdb_arrow_array_scan`, `duckdb_destroy_arrow_stream` must be called on the out stream.

Syntax

```
           duckdb_state duckdb_arrow_array_scan(
  duckdb_connection connection,
  const char *table_name,
  duckdb_arrow_schema arrow_schema,
  duckdb_arrow_array arrow_array,
  duckdb_arrow_stream *out_stream
);
```

Parameters

- `connection`: The connection on which to execute the scan.
- `table_name`: Name of the temporary view to create.
- `arrow_schema`: Arrow schema wrapper.
- `arrow_array`: Arrow array wrapper.
- `out_stream`: Output array stream that wraps around the passed schema, for releasing/deleting once done.

Return Value `DuckDBSuccess` on success or `DuckDBError` on failure.

`duckdb_execute_tasks` Execute DuckDB tasks on this thread.

Will return after `max_tasks` have been executed, or if there are no more tasks present.

Syntax

```
            void duckdb_execute_tasks(
  duckdb_database database,
  idx_t max_tasks
);
```

Parameters

- `database`: The database object to execute tasks for
- `max_tasks`: The maximum amount of tasks to execute

`duckdb_create_task_state` Creates a task state that can be used with duckdb_execute_tasks_state to execute tasks until `duckdb_finish_execution` is called on the state.

`duckdb_destroy_state` must be called on the result.

Syntax

```
            duckdb_task_state duckdb_create_task_state(
  duckdb_database database
);
```

Parameters

- `database`: The database object to create the task state for

Return Value The task state that can be used with duckdb_execute_tasks_state.

`duckdb_execute_tasks_state` Execute DuckDB tasks on this thread.

The thread will keep on executing tasks forever, until duckdb_finish_execution is called on the state. Multiple threads can share the same duckdb_task_state.

Syntax

```
            void duckdb_execute_tasks_state(
  duckdb_task_state state
);
```

Parameters

- `state`: The task state of the executor

`duckdb_execute_n_tasks_state` Execute DuckDB tasks on this thread.

The thread will keep on executing tasks until either duckdb_finish_execution is called on the state, max_tasks tasks have been executed or there are no more tasks to be executed.

Multiple threads can share the same duckdb_task_state.

Syntax

```
            idx_t duckdb_execute_n_tasks_state(
  duckdb_task_state state,
  idx_t max_tasks
);
```

Parameters

- `state`: The task state of the executor
- `max_tasks`: The maximum amount of tasks to execute

Return Value The amount of tasks that have actually been executed

`duckdb_finish_execution` Finish execution on a specific task.

Syntax

```
            void duckdb_finish_execution(
  duckdb_task_state state
);
```

Parameters

- `state`: The task state to finish execution

`duckdb_task_state_is_finished` Check if the provided duckdb_task_state has finished execution

Syntax

```
            bool duckdb_task_state_is_finished(
  duckdb_task_state state
);
```

Parameters

- `state`: The task state to inspect

Return Value Whether or not duckdb_finish_execution has been called on the task state

`duckdb_destroy_task_state` Destroys the task state returned from duckdb_create_task_state.

Note that this should not be called while there is an active duckdb_execute_tasks_state running on the task state.

Syntax

```
            void duckdb_destroy_task_state(
  duckdb_task_state state
);
```

Parameters

- `state`: The task state to clean up

`duckdb_execution_is_finished` Returns true if the execution of the current query is finished.

Syntax

```
            bool duckdb_execution_is_finished(
  duckdb_connection con
);
```

Parameters

- `con`: The connection on which to check

`duckdb_stream_fetch_chunk`

> **Warning.** Deprecation notice. This method is scheduled for removal in a future release.

Fetches a data chunk from the (streaming) duckdb_result. This function should be called repeatedly until the result is exhausted.

The result must be destroyed with `duckdb_destroy_data_chunk`.

This function can only be used on duckdb_results created with 'duckdb_pending_prepared_streaming'

If this function is used, none of the other result functions can be used and vice versa (i.e., this function cannot be mixed with the legacy result functions or the materialized result functions).

It is not known beforehand how many chunks will be returned by this result.

Syntax

```
            duckdb_data_chunk duckdb_stream_fetch_chunk(
  duckdb_result result
);
```

Parameters

- `result`: The result object to fetch the data chunk from.

Return Value The resulting data chunk. Returns `NULL` if the result has an error.

`duckdb_fetch_chunk` Fetches a data chunk from a duckdb_result. This function should be called repeatedly until the result is exhausted.

The result must be destroyed with `duckdb_destroy_data_chunk`.

It is not known beforehand how many chunks will be returned by this result.

Syntax

```
            duckdb_data_chunk duckdb_fetch_chunk(
  duckdb_result result
);
```

Parameters

- `result`: The result object to fetch the data chunk from.

Return Value The resulting data chunk. Returns `NULL` if the result has an error.

`duckdb_create_cast_function` Creates a new cast function object.

Return Value The cast function object.

Syntax

```
duckdb_cast_function duckdb_create_cast_function(

);
```

`duckdb_cast_function_set_source_type` Sets the source type of the cast function.

Syntax

```
void duckdb_cast_function_set_source_type(
  duckdb_cast_function cast_function,
  duckdb_logical_type source_type
);
```

Parameters

- `cast_function`: The cast function object.
- `source_type`: The source type to set.

`duckdb_cast_function_set_target_type` Sets the target type of the cast function.

Syntax

```
void duckdb_cast_function_set_target_type(
  duckdb_cast_function cast_function,
  duckdb_logical_type target_type
);
```

Parameters

- `cast_function`: The cast function object.
- `target_type`: The target type to set.

`duckdb_cast_function_set_implicit_cast_cost` Sets the ”cost” of implicitly casting the source type to the target type using this function.

Syntax

```
void duckdb_cast_function_set_implicit_cast_cost(
  duckdb_cast_function cast_function,
  int64_t cost
);
```

Parameters

- `cast_function`: The cast function object.
- `cost`: The cost to set.

`duckdb_cast_function_set_function` Sets the actual cast function to use.

Syntax

```
            void duckdb_cast_function_set_function(
  duckdb_cast_function cast_function,
  duckdb_cast_function_t function
);
```

Parameters

- `cast_function`: The cast function object.
- `function`: The function to set.

`duckdb_cast_function_set_extra_info` Assigns extra information to the cast function that can be fetched during execution, etc.

Syntax

```
            void duckdb_cast_function_set_extra_info(
  duckdb_cast_function cast_function,
  void *extra_info,
  duckdb_delete_callback_t destroy
);
```

Parameters

- `extra_info`: The extra information
- `destroy`: The callback that will be called to destroy the extra information (if any)

`duckdb_cast_function_get_extra_info` Retrieves the extra info of the function as set in `duckdb_cast_function_set_extra_info`.

Syntax

```
            void *duckdb_cast_function_get_extra_info(
  duckdb_function_info info
);
```

Parameters

- `info`: The info object.

Return Value The extra info.

`duckdb_cast_function_get_cast_mode` Get the cast execution mode from the given function info.

Syntax

```
            duckdb_cast_mode duckdb_cast_function_get_cast_mode(
  duckdb_function_info info
);
```

Parameters

- `info`: The info object.

Return Value The cast mode.

`duckdb_cast_function_set_error` Report that an error has occurred while executing the cast function.

Syntax

```
            void duckdb_cast_function_set_error(
  duckdb_function_info info,
  const char *error
);
```

Parameters

- `info`: The info object.
- `error`: The error message.

`duckdb_cast_function_set_row_error` Report that an error has occurred while executing the cast function, setting the corresponding output row to NULL.

Syntax

```
            void duckdb_cast_function_set_row_error(
  duckdb_function_info info,
  const char *error,
  idx_t row,
  duckdb_vector output
);
```

Parameters

- `info`: The info object.
- `error`: The error message.
- `row`: The index of the row within the output vector to set to NULL.
- `output`: The output vector.

`duckdb_register_cast_function` Registers a cast function within the given connection.

Syntax

```
            duckdb_state duckdb_register_cast_function(
  duckdb_connection con,
  duckdb_cast_function cast_function
);
```

Parameters

- `con`: The connection to use.
- `cast_function`: The cast function to register.

Return Value Whether or not the registration was successful.

`duckdb_destroy_cast_function` Destroys the cast function object.

Syntax

```
            void duckdb_destroy_cast_function(
  duckdb_cast_function *cast_function
);
```

Parameters

- `cast_function`: The cast function object.

`duckdb_destroy_expression` Destroys the expression and de-allocates its memory.

Syntax

```
            void duckdb_destroy_expression(
  duckdb_expression *expr
);
```

Parameters

- `expr`: A pointer to the expression.

`duckdb_expression_return_type` Returns the return type of an expression.

Syntax

```
            duckdb_logical_type duckdb_expression_return_type(
  duckdb_expression expr
);
```

Parameters

- `expr`: The expression.

Return Value The return type. Must be destroyed with `duckdb_destroy_logical_type`.

`duckdb_expression_is_foldable` Returns whether the expression is foldable into a value or not.

Syntax

```
            bool duckdb_expression_is_foldable(
  duckdb_expression expr
);
```

Parameters

- `expr`: The expression.

Return Value True, if the expression is foldable, else false.

`duckdb_expression_fold` Folds an expression creating a folded value.

Syntax

```
            duckdb_error_data duckdb_expression_fold(
  duckdb_client_context context,
  duckdb_expression expr,
  duckdb_value *out_value
);
```

Parameters

- `context`: The client context.
- `expr`: The expression. Must be foldable.
- `out_value`: The folded value, if folding was successful. Must be destroyed with `duckdb_destroy_value`.

Return Value The error data. Must be destroyed with `duckdb_destroy_error_data`.

C++ API

> Installation To use the DuckDB C++ API, download the `libduckdb` archive for your platform.
>
> The latest stable version of the DuckDB C++ API is 1.5.4.

> **Warning.** DuckDB's C++ API is internal. It is not guaranteed to be stable and can change without notice. If you would like to build an application on DuckDB, we recommend using the C API.

Installation

The DuckDB C++ API can be installed as part of the `libduckdb` packages. Please see the installation page for details.

Basic API Usage

DuckDB implements a custom C++ API. This is built around the abstractions of a database instance (`DuckDB` class), multiple `Connections` to the database instance and `QueryResult` instances as the result of queries. The header file for the C++ API is `duckdb.hpp`.

Startup & Shutdown

To use DuckDB, you must first initialize a `DuckDB` instance using its constructor. `DuckDB()` takes as parameter the database file to read and write from. The special value `nullptr` can be used to create an **in-memory database**. Note that for an in-memory database no data is persisted to disk (i.e., all data is lost when you exit the process). The second parameter to the `DuckDB` constructor is an optional `DBConfig` object. In `DBConfig`, you can set various database parameters, for example the read/write mode or memory limits. The `DuckDB` constructor may throw exceptions, for example if the database file is not usable.

With the `DuckDB` instance, you can create one or many `Connection` instances using the `Connection()` constructor. While connections should be thread-safe, they will be locked during querying. It is therefore recommended that each thread uses its own connection if you are in a multithreaded environment.

```
DuckDB db(nullptr);
Connection con(db);
```

Querying

Connections expose the `Query()` method to send a SQL query string to DuckDB from C++. `Query()` fully materializes the query result as a `MaterializedQueryResult` in memory before returning at which point the query result can be consumed. There is also a streaming API for queries, see further below.

```
// create a table
con.Query("CREATE TABLE integers (i INTEGER, j INTEGER)");

// insert three rows into the table
con.Query("INSERT INTO integers VALUES (3, 4), (5, 6), (7, NULL)");

auto result = con.Query("SELECT * FROM integers");
if (result->HasError()) {
    cerr << result->GetError() << endl;
```

```
} else {
    cout << result->ToString() << endl;
}
```

The `MaterializedQueryResult` instance contains firstly two fields that indicate whether the query was successful. `Query` will not throw exceptions under normal circumstances. Instead, invalid queries or other issues will lead to the `success` Boolean field in the query result instance to be set to `false`. In this case an error message may be available in `error` as a string. The methods `GetErrorType()` and `GetErrorObject()` are also available for any `QueryResult` instance which may aid in more explicit error handling.

```
auto result = con.Query("INSERT INTO integers VALUES (1, 2)");
if (result->HasError()) {
    auto errorType = result->GetErrorType();
    switch (errorType) {
    case duckdb::ExceptionType::CONSTRAINT: {
        // Example handling
        auto errorObject = result->GetErrorObject();
        errorObject.ConvertErrorToJSON();
        std::cout << errorObject.Message() << std::endl;
        break;
    }
    // More handling
    }
} else {
    // Normal code
}
```

If successful, other fields are set: the type of statement that was just executed (e.g., `StatementType::INSERT_STATEMENT`) is contained in `statement_type`. The high-level ("Logical type"/"SQL type") types of the result set columns are in `types`. The names of the result columns are in the `names` string vector. In case multiple result sets are returned, for example because the result set contained multiple statements, the result set can be chained using the `next` field.

DuckDB also supports prepared statements in the C++ API with the `Prepare()` method. This returns an instance of `PreparedStatement`. This instance can be used to execute the prepared statement with parameters. Below is an example:

```
std::unique_ptr<PreparedStatement> prepare = con.Prepare("SELECT count(*) FROM a WHERE i = $1");
std::unique_ptr<QueryResult> result = prepare->Execute(12);
```

> **Warning.** Do **not** use prepared statements to insert large amounts of data into DuckDB. See the data import documentation for better options.

UDF API

The UDF API allows the definition of user-defined functions. It is exposed in `duckdb:Connection` through the methods: `CreateScalarFunction()`, `CreateVectorizedFunction()`, and variants. These methods create UDFs in the temporary schema (`TEMP_SCHEMA`) of the owner connection that is the only one allowed to use and change them.

CreateScalarFunction The user can code an ordinary scalar function and invoke the `CreateScalarFunction()` to register and afterward use the UDF in a `SELECT` statement, for instance:

```
bool bigger_than_four(int value) {
    return value > 4;
}

connection.CreateScalarFunction<bool, int>("bigger_than_four", &bigger_than_four);

connection.Query("SELECT bigger_than_four(i) FROM (VALUES (3), (5)) tbl(i)")->Print();
```

The `CreateScalarFunction()` methods automatically create vectorized scalar UDFs so they are as efficient as built-in functions, we have two variants of this method interface as follows:

1.

```
template<typename TR, typename... Args>
void CreateScalarFunction(string name, TR (*udf_func)(Args…))
```

- template parameters:
  - **TR** is the return type of the UDF function.
  - **Args** are the arguments up to 3 for the UDF function (this method only supports until ternary functions).
- **name** is the name to register the UDF function.
- **udf_func** is a pointer to the UDF function.

This method automatically discovers from the template typenames the corresponding LogicalTypes:

- `bool` → `LogicalType::BOOLEAN`
- `int8_t` → `LogicalType::TINYINT`
- `int16_t` → `LogicalType::SMALLINT`
- `int32_t` → `LogicalType::INTEGER`
- `int64_t` → `LogicalType::BIGINT`
- `float` → `LogicalType::FLOAT`
- `double` → `LogicalType::DOUBLE`
- `string_t` → `LogicalType::VARCHAR`

In DuckDB some primitive types, e.g., `int32_t`, are mapped to the same `LogicalType`: `INTEGER`, `TIME` and `DATE`, then for disambiguation the users can use the following overloaded method.

2.

```
template<typename TR, typename... Args>
void CreateScalarFunction(string name, vector<LogicalType> args, LogicalType ret_type, TR (*udf_
func)(Args…))
```

An example of use would be:

```
int32_t udf_date(int32_t a) {
    return a;
}

con.Query("CREATE TABLE dates (d DATE)");
con.Query("INSERT INTO dates VALUES ('1992-01-01')");

con.CreateScalarFunction<int32_t, int32_t>("udf_date", {LogicalType::DATE}, LogicalType::DATE, &udf_
date);

con.Query("SELECT udf_date(d) FROM dates")->Print();
```

- template parameters:
  - **TR** is the return type of the UDF function.
  - **Args** are the arguments up to 3 for the UDF function (this method only supports until ternary functions).
- **name** is the name to register the UDF function.
- **args** are the LogicalType arguments that the function uses, which should match with the template Args types.
- **ret_type** is the LogicalType of return of the function, which should match with the template TR type.
- **udf_func** is a pointer to the UDF function.

This function checks the template types against the LogicalTypes passed as arguments and they must match as follows:

- LogicalTypeId::BOOLEAN → bool

- LogicalTypeId::TINYINT → int8_t
- LogicalTypeId::SMALLINT → int16_t
- LogicalTypeId::DATE, LogicalTypeId::TIME, LogicalTypeId::INTEGER → int32_t
- LogicalTypeId::BIGINT, LogicalTypeId::TIMESTAMP → int64_t
- LogicalTypeId::FLOAT, LogicalTypeId::DOUBLE, LogicalTypeId::DECIMAL → double
- LogicalTypeId::VARCHAR, LogicalTypeId::CHAR, LogicalTypeId::BLOB → string_t
- LogicalTypeId::VARBINARY → blob_t

CreateVectorizedFunction The `CreateVectorizedFunction()` methods register a vectorized UDF such as:

```
/*
* This vectorized function copies the input values to the result vector
*/
template<typename TYPE>
static void udf_vectorized(DataChunk &args, ExpressionState &state, Vector &result) {
    // set the result vector type
    result.vector_type = VectorType::FLAT_VECTOR;
    // get a raw array from the result
    auto result_data = FlatVector::GetData<TYPE>(result);

    // get the solely input vector
    auto &input = args.data[0];
    // now get an orrified vector
    VectorData vdata;
    input.Orrify(args.size(), vdata);

    // get a raw array from the orrified input
    auto input_data = (TYPE *)vdata.data;

    // handling the data
    for (idx_t i = 0; i < args.size(); i++) {
        auto idx = vdata.sel->get_index(i);
        if ((*vdata.nullmask)[idx]) {
            continue;
        }
        result_data[i] = input_data[idx];
    }
}

con.Query("CREATE TABLE integers (i INTEGER)");
con.Query("INSERT INTO integers VALUES (1), (2), (3), (999)");

con.CreateVectorizedFunction<int, int>("udf_vectorized_int", &&udf_vectorized<int>);

con.Query("SELECT udf_vectorized_int(i) FROM integers")->Print();
```

The Vectorized UDF is a pointer of the type *scalar_function_t*:

```
typedef std::function<void(DataChunk &args, ExpressionState &expr, Vector &result)> scalar_function_t;
```

- **args** is a DataChunk that holds a set of input vectors for the UDF that all have the same length.
- **expr** is an ExpressionState that provides information to the query's expression state.
- **result** is a Vector to store the result values.

There are different vector types to handle in a Vectorized UDF:

- ConstantVector
- DictionaryVector
- FlatVector

- ListVector
- StringVector
- StructVector
- SequenceVector

The general API of the `CreateVectorizedFunction()` method is as follows:

1.

```
template<typename TR, typename... Args>
void CreateVectorizedFunction(string name, scalar_function_t udf_func, LogicalType varargs =
LogicalType::INVALID)
```

- template parameters:
  - **TR** is the return type of the UDF function.
  - **Args** are the arguments up to 3 for the UDF function.
- **name** is the name to register the UDF function.
- **udf_func** is a *vectorized* UDF function.
- **varargs** The type of varargs to support, or LogicalTypeId::INVALID (default value) if the function does not accept variable length arguments.

This method automatically discovers from the template typenames the corresponding LogicalTypes:

- `bool` → `LogicalType::BOOLEAN`
- `int8_t` → `LogicalType::TINYINT`
- `int16_t` → `LogicalType::SMALLINT`
- `int32_t` → `LogicalType::INTEGER`
- `int64_t` → `LogicalType::BIGINT`
- `float` → `LogicalType::FLOAT`
- `double` → `LogicalType::DOUBLE`
- `string_t` → `LogicalType::VARCHAR`

2.

```
template<typename TR, typename... Args>
void CreateVectorizedFunction(string name, vector<LogicalType> args, LogicalType ret_type, scalar_
function_t udf_func, LogicalType varargs = LogicalType::INVALID)
```

CLI

Command Line Client

> Installation To use the DuckDB CLI client, visit the CLI installation page.
>
> The latest stable version of the DuckDB command line client is 1.5.4.

Installation

The DuckDB CLI (Command Line Interface) is a single, dependency-free executable. It is precompiled for Windows, Mac and Linux for both the stable version and for nightly builds produced by GitHub Actions. Please see the installation page under the CLI tab for download links.

The DuckDB CLI is based on the SQLite command line shell, so CLI-client-specific functionality is similar to what is described in the SQLite documentation (although DuckDB's SQL syntax follows PostgreSQL conventions with a few exceptions).

> DuckDB has a tldr page, which summarizes the most common uses of the CLI client. If you have tldr installed, you can display it by running `tldr duckdb`.

Getting Started

Once the CLI executable has been downloaded, unzip it and save it to any directory. Navigate to that directory in a terminal and enter the command `duckdb` to run the executable. If in a PowerShell or POSIX shell environment, use the command `./duckdb` instead.

Usage

The typical usage of the `duckdb` command is the following:

```
duckdb <OPTIONS> <FILENAME>
```

Options

The `<OPTIONS>`{:.language-sql .highlight} part encodes arguments for the CLI client. Common options include:

- `-csv`: sets the output mode to CSV
- `-json`: sets the output mode to JSON
- `-readonly`: open the database in read-only mode (see concurrency in DuckDB)

For a full list of options, see the command line arguments page.

In-Memory vs. Persistent Database

When no `<FILENAME>`{:.language-sql .highlight} argument is provided, the DuckDB CLI will open a temporary in-memory database. You will see DuckDB's version number, the information on the connection and a prompt starting with a D.

```
duckdb
```

```
DuckDB v1.5.4 ({{ site.current_duckdb_codename }}) 08e34c447b
Enter ".help" for usage hints.
Connected to a transient in-memory database.
Use ".open FILENAME" to reopen on a persistent database.
D
```

To open or create a persistent database, simply include a path as a command line argument:

```
duckdb my_database.duckdb
```

Running SQL Statements in the CLI

Once the CLI has been opened, enter a SQL statement followed by a semicolon, then hit enter and it will be executed. Results will be displayed in a table in the terminal. If a semicolon is omitted, hitting enter will allow for multi-line SQL statements to be entered.

```
SELECT 'quack' AS my_column;
```

my_column
quack

The CLI supports all of DuckDB's rich SQL syntax including `SELECT`, `CREATE` and `ALTER` statements.

Editor Features

The CLI supports autocompletion, and has sophisticated editor features and syntax highlighting on macOS, Linux and Windows.

Exiting the CLI

To exit the CLI, press `Ctrl+D` if your platform supports it. Otherwise, press `Ctrl+C` or use the `.exit` command. If you used a persistent database, DuckDB will automatically checkpoint (save the latest edits to disk) and close. This will remove the `.wal` file (the write-ahead log) and consolidate all of your data into the single-file database.

Dot Commands

In addition to SQL syntax, special dot commands may be entered into the CLI client. To use one of these commands, begin the line with a period (`.`) immediately followed by the name of the command you wish to execute. Additional arguments to the command are entered, space separated, after the command. If an argument must contain a space, either single or double quotes may be used to wrap that parameter. Dot commands must be entered on a single line, and no whitespace may occur before the period. No semicolon is required at the end of the line.

Frequently-used configurations can be stored in the file `~/.duckdbrc`, which will be loaded when starting the CLI client. See the Configuring the CLI section below for further information on these options.

> **Tip.** To prevent the DuckDB CLI client from reading the `~/.duckdbrc` file, start it as follows:
>
> ```
> duckdb -init /dev/null
> ```

Below, we summarize a few important dot commands. To see all available commands, see the dot commands page or use the `.help` command.

Opening Database Files In addition to connecting to a database when opening the CLI, a new database connection can be made by using the `.open` command. If no additional parameters are supplied, a new in-memory database connection is created. This database will not be persisted when the CLI connection is closed.

```
.open
```

The `.open` command optionally accepts several options, but the final parameter can be used to indicate a path to a persistent database (or where one should be created). The special string `:memory:` can also be used to open a temporary in-memory database.

```
.open persistent.duckdb
```

> **Warning.** `.open` closes the current database. To keep the current database, while adding a new database, use the ATTACH statement.

One important option accepted by `.open` is the `--readonly` flag. This disallows any editing of the database. To open in read only mode, the database must already exist. This also means that a new in-memory database can't be opened in read only mode since in-memory databases are created upon connection.

```
.open --readonly preexisting.duckdb
```

The `--sql` option allows setting the database path using a SQL expression:

```
.open --sql "getenv('MY_DB_PATH')"
```

Output Formats The `.mode` dot command may be used to change the appearance of the tables returned in the terminal output. These include the default `duckbox` mode, `csv` and `json` mode for ingestion by other tools, `markdown` and `latex` for documents and `insert` mode for generating SQL statements.

Writing Results to a File By default, the DuckDB CLI sends results to the terminal's standard output. However, this can be modified using either the `.output` or `.once` commands. For details, see the documentation for the output dot command.

Reading SQL from a File The DuckDB CLI can read both SQL commands and dot commands from an external file instead of the terminal using the `.read` command. This allows for a number of commands to be run in sequence and allows command sequences to be saved and reused.

The `.read` command requires only one argument: the path to the file containing the SQL and/or commands to execute. After running the commands in the file, control will revert back to the terminal. Output from the execution of that file is governed by the same `.output` and `.once` commands that have been discussed previously. This allows the output to be displayed back to the terminal, as in the first example below, or out to another file, as in the second example.

In this example, the file `select_example.sql` is located in the same directory as duckdb.exe and contains the following SQL statement:

```
SELECT *
FROM generate_series(5);
```

To execute it from the CLI, the `.read` command is used.

```
.read select_example.sql
```

The output below is returned to the terminal by default. The formatting of the table can be adjusted using the `.output` or `.once` commands.

```
| generate_series |
|-----------------:|
| 0               |
| 1               |
| 2               |
| 3               |
| 4               |
| 5               |
```

Multiple commands, including both SQL and dot commands, can also be run in a single `.read` command. In this example, the file `write_markdown_to_file.sql` is located in the same directory as duckdb.exe and contains the following commands:

```
.mode markdown
.output series.md
SELECT *
FROM generate_series(5);
```

To execute it from the CLI, the `.read` command is used as before.

```
.read write_markdown_to_file.sql
```

In this case, no output is returned to the terminal. Instead, the file `series.md` is created (or replaced if it already existed) with the markdown-formatted results shown here:

```
| generate_series |
|-----------------:|
| 0               |
| 1               |
| 2               |
| 3               |
| 4               |
| 5               |
```

Configuring the CLI

Several dot commands can be used to configure the CLI. On startup, the CLI reads and executes all commands in the file `~/.duckdbrc`, including dot commands and SQL statements. This allows you to store the configuration state of the CLI. You may also point to a different initialization file using the `-init` flag.

Setting a Custom Prompt

As an example, a file in the same directory as the DuckDB CLI named `prompt.sql` will change the DuckDB prompt to be a duck head and run a SQL statement. Note that the duck head is built with Unicode characters and does not work in all terminal environments (e.g., in Windows, unless running with WSL and using the Windows Terminal).

```
.prompt "{color:yellow1}{sql:select current_database()} 🐥 "
```

Or a simpler version without colours:

```
.prompt "{sql:select current_database()} 🐥 "
```

To invoke that file on initialization, use this command:

```
duckdb -init prompt.sql
```

This outputs:

```
-- Loading resources from prompt.sql
v<version> <git_hash>
Enter ".help" for usage hints.
Connected to a transient in-memory database.
Use ".open FILENAME" to reopen on a persistent database.
🐥
```

Non-Interactive Usage

To read/process a file and exit immediately, redirect the file contents in to `duckdb`:

```
duckdb < select_example.sql
```

To execute a command with SQL text passed in directly from the command line, call `duckdb` with two arguments: the database location (or `:memory:`), and a string with the SQL statement to execute.

```
duckdb :memory: "SELECT 42 AS the_answer"
```

Loading Extensions

To load extensions, use DuckDB's SQL `INSTALL` and `LOAD` commands as you would other SQL statements.

```
INSTALL fts;
LOAD fts;
```

For details, see the Extension docs.

Reading from stdin and Writing to stdout

When in a Unix environment, it can be useful to pipe data between multiple commands. DuckDB is able to read data from stdin as well as write to stdout using the file location of stdin (`/dev/stdin`) and stdout (`/dev/stdout`) within SQL commands, as pipes act very similarly to file handles.

This command will create an example CSV:

```
COPY (SELECT 42 AS woot UNION ALL SELECT 43 AS woot) TO 'test.csv' (HEADER);
```

First, read a file and pipe it to the `duckdb` CLI executable. As arguments to the DuckDB CLI, pass in the location of the database to open, in this case, an in-memory database, and a SQL command that utilizes `/dev/stdin` as a file location.

```
cat test.csv | duckdb -c "SELECT * FROM read_csv('/dev/stdin')"
```

woot
42
43

To write back to stdout, the copy command can be used with the `/dev/stdout` file location.

```
cat test.csv | \
    duckdb -c "COPY (SELECT * FROM read_csv('/dev/stdin')) TO '/dev/stdout' WITH (FORMAT csv, HEADER)"
```

```
woot
42
43
```

Reading Environment Variables

The `getenv` function can read environment variables.

Examples

To retrieve the home directory's path from the `HOME` environment variable, use:

```
SELECT getenv('HOME') AS home;
```

home
/Users/user_name

The output of the `getenv` function can be used to set configuration options. For example, to set the `NULL` order based on the environment variable `DEFAULT_NULL_ORDER`, use:

```
SET default_null_order = getenv('DEFAULT_NULL_ORDER');
```

Restrictions for Reading Environment Variables

The `getenv` function can only be run when the `enable_external_access` option is set to `true` (the default setting). It is only available in the CLI client and is not supported in other DuckDB clients.

Prepared Statements

The DuckDB CLI supports executing prepared statements in addition to regular `SELECT` statements. To create and execute a prepared statement in the CLI client, use the `PREPARE` clause and the `EXECUTE` statement.

Query Completion ETA

DuckDB's CLI now provides intelligent time-to-completion estimates for running queries and displays total execution time upon completion.

When executing queries in the DuckDB CLI, the progress bar displays an estimated time remaining until completion. This feature employs advanced statistical modeling (Kalman filtering) to deliver more accurate predictions than simple linear extrapolation.

How It Works

DuckDB calculates the estimated time to completion through the following process:

1. Progress Monitoring: DuckDB's internal progress API reports the estimated completion percentage for the running query
2. Statistical Filtering: A Kalman filter smooths noisy progress measurements and accounts for execution variability
3. Continuous Refinement: The system continuously updates predicted completion time as new progress data becomes available, improving accuracy throughout execution

The Kalman filter adapts to changing execution conditions such as memory pressure, I/O bottlenecks, or network delays. This adaptive approach means estimated completion times may not always decrease linearly—estimates can increase when query execution becomes less predictable.

Factors Affecting The Accuracy of Query Completion ETA

Completion time estimates may be less reliable under these conditions:

System resource constraints:

- Memory pressure causing disk swapping
- High CPU load from competing processes
- Disk I/O bottlenecks

Query execution characteristics:

- Variable execution phases (initial setup versus main processing)

- Network-dependent operations with inconsistent latency
- Queries with unpredictable branching logic
- Operations on remote data sources
- External function calls
- Highly skewed data distributions

Command Line Arguments

The table below summarizes DuckDB's command line options. To list all command line options, use the command:

```
duckdb -help
```

For a list of dot commands available in the CLI shell, see the Dot Commands page.

Argument	Description
`-append`	Append the database to the end of the file
`-ascii`	Set output mode to `ascii`
`-bail`	Stop after hitting an error
`-batch`	Force batch I/O
`-box`	Set output mode to `box`
`-column`	Set output mode to `column`
`-cmd COMMAND`	Run `COMMAND` before reading `stdin`
`-c COMMAND`	Run `COMMAND` and exit
`-csv`	Set output mode to `csv`
`-echo`	Print commands before execution
`-f FILENAME`	Run the script in `FILENAME` and exit. Note that the `~/.duckdbrc` is read and executed first (if it exists)
`-init FILENAME`	Run the script in `FILENAME` upon startup (instead of `~/.duckdbrc`)
`-header`	Turn headers on
`-help`	Show this message
`-html`	Set output mode to HTML
`-interactive`	Force interactive I/O
`-json`	Set output mode to `json`
`-line`	Set output mode to `line`

Argument	Description
`-list`	Set output mode to `list`
`-markdown`	Set output mode to `markdown`
`-newline SEP`	Set output row separator. Default: `\n`
`-nofollow`	Refuse to open symbolic links to database files
`-noheader`	Turn headers off
`-no-stdin`	Exit after processing options instead of reading stdin
`-nullvalue TEXT`	Set text string for `NULL` values. Default: `NULL`
`-quote`	Set output mode to `quote`
`-readonly`	Open the database read-only. This option also supports attaching to remote databases via HTTPS
`-s COMMAND`	Run `COMMAND` and exit
`-separator SEP`	Set output column separator to `SEP`. Default: `|`
`-storage-version VER`	Database storage compatibility version to use. To use the latest storage version, pass `-storage-version latest`
`-table`	Set output mode to `table`
`-ui`	Loads and starts the DuckDB UI. If the UI is not yet installed, it installs the `ui` extension
`-unsigned`	Allow loading of unsigned extensions. This option is intended to be used for developing extensions. Consult the Securing DuckDB page for guidelines on how to set up DuckDB in a secure manner
`-version`	Show DuckDB version

Passing a Sequence of Arguments

Note that the CLI arguments are processed in order, similarly to the behavior of the SQLite CLI. For example:

```
duckdb -csv -c 'SELECT 42 AS hello' -json -c 'SELECT 84 AS world'
```

Returns the following:

```
hello
42
```

```
[{"world":84}]
```

Dot Commands

Dot commands are available in the DuckDB CLI client. To use one of these commands, begin the line with a period (`.`) immediately followed by the name of the command you wish to execute. Additional arguments to the command are entered, space separated, after the command. If an argument must contain a space, either single or double quotes may be used to wrap that parameter. Dot commands must be entered on a single line, and no whitespace may occur before the period. No semicolon is required at the end of the line. To see available commands, use the `.help` command.

List of Dot Commands

Command	Description
`.bail <on/off>`{:.language-sql .highlight}	Stop after hitting an error. Default: `off`
`.binary <on/off>`{:.language-sql .highlight}	Turn binary output on or `off`. Default: `off`
`.cd <DIRECTORY>`{:.language-sql .highlight}	Change the working directory to `DIRECTORY`
`.changes <on/off>`{:.language-sql .highlight}	Show number of rows changed by SQL
`.columns`{:.language-sql .highlight}	Column-wise rendering of query results
`.constant <COLOR>`{:.language-sql .highlight}	Sets the syntax highlighting color used for constant values
`.constantcode <CODE>`{:.language-sql .highlight}	Sets the syntax highlighting terminal code used for constant values
`.databases`{:.language-sql .highlight}	List names and files of attached databases
`.dump <TABLE>`{:.language-sql .highlight}	Render database content as SQL. `TABLE` is a `LIKE` pattern for the tables to dump
`.echo <on/off>`{:.language-sql .highlight}	Turn command echo on or `off`
`.exit <CODE>`{:.language-sql .highlight}	Exit this program with return-code `CODE`
`.headers <on/off>`{:.language-sql .highlight}	Turn display of headers on or `off`. Does not apply to duckbox mode
`.help <-all> <PATTERN>`{:.language-sql .highlight}	Show help text for `PATTERN`. Use `.help shortcuts` to display keyboard shortcuts
`.highlight <on/off>`{:.language-sql .highlight}	Toggle syntax highlighting in the shell on / `off`. See the query syntax highlighting section for more details
`.highlight_colors <COMPONENT> <COLOR>`{:.language-sql .highlight}	Configure the color of each component in (duckbox only). See the result syntax highlighting section for more details

Command	Description
`.highlight_mode <mixed/dark/light>`{:.language-sql .highlight}	Toggle the highlight mode. See the dark/light mode section for details
`.highlight_results <on/off>`{:.language-sql .highlight}	Toggle highlighting in result tables on / `off` (duckbox only). See the result syntax highlighting section for more details
`.import <FILE> <TABLE>`{:.language-sql .highlight}	Import data from `FILE` into `TABLE`. Supports `--csv`, `--json`, `--parquet` options
`.indexes <TABLE>`{:.language-sql .highlight}	Show names of indexes
`.keyword <COLOR>`{:.language-sql .highlight}	Sets the syntax highlighting color used for keywords
`.keywordcode <CODE>`{:.language-sql .highlight}	Sets the syntax highlighting terminal code used for keywords
`.large_number_rendering <all/footer/off>`{:.language-sql .highlight}	Toggle readable rendering of large numbers (duckbox only, default: `footer`)
`.last`{:.language-sql .highlight}	Render the last result without truncating. Useful for navigating with the pager
`.log <FILE/off>`{:.language-sql .highlight}	Turn logging on or `off`. `FILE` can be `stderr` / `stdout`
`.maxrows <COUNT>`{:.language-sql .highlight}	Sets the maximum number of rows for display. Only for duckbox mode
`.maxwidth <COUNT>`{:.language-sql .highlight}	Sets the maximum width in characters. 0 defaults to terminal width. Only for duckbox mode
`.mode <MODE> <TABLE>`{:.language-sql .highlight}	Set output mode
`.multiline`{:.language-sql .highlight}	Set multi-line mode (default)
`.nullvalue <STRING>`{:.language-sql .highlight}	Use `STRING` in place of `NULL` values. Default: `NULL`
`.once <OPTIONS> <FILE>`{:.language-sql .highlight}	Output for the next SQL command only to `FILE`
`.open <OPTIONS> <FILE>`{:.language-sql .highlight}	Close existing database and reopen `FILE`. Options: `--new`, `--nofollow`, `--readonly`, `--sql`
`.output <FILE>`{:.language-sql .highlight}	Send output to `FILE` or `stdout` if `FILE` is omitted
`.pager <OPTIONS>`{:.language-sql .highlight}	Control pager usage for output. See the paging section for details
`.print <STRING...>`{:.language-sql .highlight}	Print literal `STRING`
`.progress_bar <COMPONENT>`{:.language-sql .highlight}	Set the progress bar component styles

Command	Description
`.prompt <OPTIONS> <CONTINUE>`{:.language-sql .highlight}	Replace the standard prompts
`.quit`{:.language-sql .highlight}	Exit this program
`.read <FILE>`{:.language-sql .highlight}	Read input from `FILE`
`.rows`{:.language-sql .highlight}	Row-wise rendering of query results (default)
`.safe_mode`{:.language-sql .highlight}	Activates safe mode
`.schema <PATTERN>`{:.language-sql .highlight}	Show the `CREATE` statements matching `PATTERN`
`.separator <COL> <ROW>`{:.language-sql .highlight}	Change the column and row separators
`.shell <CMD> <ARGS...>`{:.language-sql .highlight}	Run `CMD` with `ARGS...` in a system shell
`.show`{:.language-sql .highlight}	Show the current values for various settings
`.singleline`{:.language-sql .highlight}	Set single-line mode
`.startup_text <none/version/all>`{:.language-sql .highlight}	Controls the start-up text displayed when launching the CLI. Set this as the first line in `~/.duckdbrc`
`.system <CMD> <ARGS...>`{:.language-sql .highlight}	Run `CMD` with `ARGS...` in a system shell
`.tables <TABLE>`{:.language-sql .highlight}	List tables matching `LIKE` pattern `TABLE` with column names, types and row counts, grouped by database and schema
`.timer <on/off>`{:.language-sql .highlight}	Turn SQL timer on or `off`. SQL statements separated by `;` but *not* separated via newline are measured together
`.width <NUM1> <NUM2> ...`{:.language-sql .highlight}	Set minimum column widths for columnar output

Using the `.help` Command

The `.help` text may be filtered by passing in a text string as the first argument.

```
.help m
```

```
.maxrows COUNT          Sets the maximum number of rows for display (default: 40). Only for duckbox mode.
.maxwidth COUNT          Sets the maximum width in characters. 0 defaults to terminal width. Only for
duckbox mode.
.mode MODE ?TABLE?       Set output mode
```

`.output`: Writing Results to a File

By default, the DuckDB CLI sends results to the terminal's standard output. However, this can be modified using either the `.output` or `.once` commands. Pass in the desired output file location as a parameter. The `.once` command will only output the next set of results and then revert to standard out, but `.output` will redirect all subsequent output to that file location. Note that each result will overwrite the entire file at that destination. To revert back to standard output, enter `.output` with no file parameter.

In this example, the output format is changed to `markdown`, the destination is identified as a Markdown file, and then DuckDB will write the output of the SQL statement to that file. Output is then reverted to standard output using `.output` with no parameter.

```
.mode markdown
.output my_results.md
SELECT 'taking flight' AS output_column;
.output
SELECT 'back to the terminal' AS displayed_column;
```

The file `my_results.md` will then contain:

```
| output_column |
| ------------- |
| taking flight |
```

The terminal will then display:

```
| displayed_column     |
| -------------------- |
| back to the terminal |
```

A common output format is CSV, or comma separated values. DuckDB supports SQL syntax to export data as CSV or Parquet, but the CLI-specific commands may be used to write a CSV instead if desired.

```
.mode csv
.once my_output_file.csv
SELECT 1 AS col_1, 2 AS col_2
UNION ALL
SELECT 10 AS col1, 20 AS col_2;
```

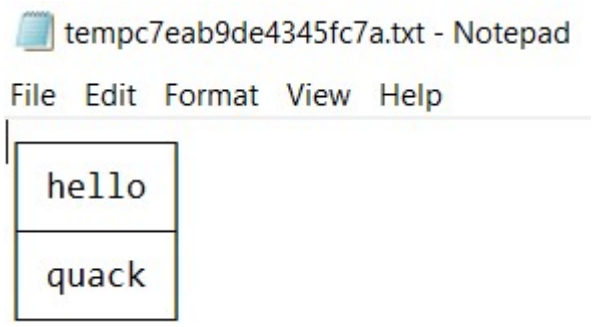
The file `my_output_file.csv` will then contain:

```
col_1,col_2
1,2
10,20
```

By passing special options (flags) to the `.once` command, query results can also be sent to a temporary file and automatically opened in the user's default program. Use either the `-e` flag for a text file (opened in the default text editor), or the `-x` flag for a CSV file (opened in the default spreadsheet editor). This is useful for more detailed inspection of query results, especially if there is a relatively large result set. The `.excel` command is equivalent to `.once -x`.

```
.once -e
SELECT 'quack' AS hello;
```

The results then open in the default text file editor of the system, for example:



> **Tip.** macOS users can copy the results to their clipboards using `pbcopy` by using `.once` to output to `pbcopy` via a pipe: `.once |pbcopy`
>
> Combining this with the `.headers off` and `.mode lines` options can be particularly effective.

Querying the Database Schema

All DuckDB clients support querying the database schema with SQL, but the CLI has additional dot commands that can make it easier to understand the contents of a database. The `.tables` command will return a list of tables in the database. It has an optional argument that will filter the results according to a `LIKE` pattern.

```
CREATE TABLE swimmers AS SELECT 'duck' AS animal;
CREATE TABLE fliers AS SELECT 'duck' AS animal;
CREATE TABLE walkers AS SELECT 'duck' AS animal;
.tables
```

```
fliers    swimmers  walkers
```

For example, to filter to only tables that contain an `l`, use the `LIKE` pattern `%l%`.

```
.tables %l%
```

```
fliers   walkers
```

The `.schema` command will show all of the SQL statements used to define the schema of the database.

```
.schema
```

```
CREATE TABLE fliers (animal VARCHAR);
CREATE TABLE swimmers (animal VARCHAR);
CREATE TABLE walkers (animal VARCHAR);
```

Dumping Database Content as SQL

The `.dump` command renders the database content as SQL statements, including both schema definitions and data. This is useful for creating backups or migrating data.

```
.dump
```

An optional `TABLE` argument filters the output using a `LIKE` pattern. Multiple patterns can be provided as additional arguments.

```
.dump %swim%
```

The `--newlines` option allows unescaped newline characters in the output:

```
.dump --newlines
```

Progress Bar

The DuckDB CLI client's progress bar supports customization through components.

The `.progress_bar` command supports `--add` and `--clear` parameters for adding and removing components.

For details on specific usage, see the examples below.

Configuring the Progress Bar Display

To check if the progress bar is enabled:

```
SELECT * FROM duckdb_settings() WHERE name = 'enable_progress_bar';
```

To check the current minimum amount of time (in milliseconds) a query needs to take before displaying a progress bar:

```
SELECT * FROM duckdb_settings() WHERE name = 'progress_bar_time';
```

To set the minimum amount of time that the progress bar displays to 100 milliseconds:

```
SET progress_bar_time = 100;
```

To set that progress bar component to a red text that displays the current time on the progress bar:

```
.progress_bar --add "{align:right}{min_size:20}{color:red}Time: {sql:select (current_
time::varchar).split('.')[1]}{color:reset} "
```

> `.progress_bar --add` commands are additive, issuing multiple `--add` calls will stack additional components on the progress bar.

To set that progress bar component to a blue text that displays the file cache RAM usage on the progress bar:

```
.progress_bar --add "{align:right}{min_size:20}{color:blue}External Cache Usage: {sql:select format_
bytes(memory_usage_bytes) from duckdb_memory() where tag='EXTERNAL_FILE_CACHE'}{color:reset};
```

To reset all existing progress bar components:

```
.progress_bar --clear
```

Syntax Highlighters

The DuckDB CLI client has a syntax highlighter for the SQL queries and another for the duckbox-formatted result tables.

Configuring the Query Syntax Highlighter

By default the shell includes support for syntax highlighting. The CLI's syntax highlighter can be configured using the following commands.

To turn off the highlighter:

```
.highlight off
```

To turn on the highlighter:

```
.highlight on
```

To configure the color used to highlight constants:

```
.constant
[red|green|yellow|blue|magenta|cyan|white|brightblack|brightred|brightgreen|brightyellow|brightblue|brightmagenta
```

```
.constantcode <terminal_code>
```

For example:

```
.constantcode 033[31m
```

To configure the color used to highlight keywords:

```
.keyword
[red|green|yellow|blue|magenta|cyan|white|brightblack|brightred|brightgreen|brightyellow|brightblue|brightmagenta
```

```
.keywordcode <terminal_code>
```

For example:

```
.keywordcode 033[31m
```

Configuring the Result Syntax Highlighter

By default, the result highlighting makes a few small modifications:

- Bold column names.
- NULL values are greyed out.
- Layout elements are grayed out.

The highlighting of each of the components can be customized using the `.highlight_colors` command. For example:

```
.highlight_colors layout red
.highlight_colors column_type yellow
.highlight_colors column_name yellow bold_underline
.highlight_colors numeric_value cyan underline
.highlight_colors temporal_value red bold
.highlight_colors string_value green bold
.highlight_colors footer gray
```

The result highlighting can be disabled using `.highlight_results off`.

Shorthands

DuckDB's CLI allows using shorthands for dot commands. Once a sequence of characters can be unambiguously completed to a dot command or an argument, the CLI (silently) autocompletes them. For example:

```
.mo ma
```

Is equivalent to:

```
.mode markdown
```

> **Tip.** Avoid using shorthands in SQL scripts to improve readability and ensure that the scripts are future-proof.

Importing Data

The `.import` command imports data from a file into a DuckDB table. It uses DuckDB's reader functions (`read_csv`, `read_json`, `read_parquet`) and supports automatic schema detection. If the target table does not exist, it is automatically created.

The file format can be specified explicitly using `--csv`, `--json`, or `--parquet`. If no format is specified, the format is inferred from the file extension.

```
.import data.csv my_table
```

Additional parameters can be passed to the underlying reader function using '--<parameter> <value>{:.language-sql .highlight} syntax:

```
.import data.csv my_table --delimiter "|" --header false
```

To import a JSON file:

```
.import data.json my_table --json
```

To import a Parquet file:

```
.import data.parquet my_table
```

Output Formats

The `.mode` dot command may be used to change the appearance of the tables returned in the terminal output. In addition to customizing the appearance, these modes have additional benefits. This can be useful for presenting DuckDB output elsewhere by redirecting the terminal output to a file. Using the `insert` mode will build a series of SQL statements that can be used to insert the data at a later point. The `markdown` mode is particularly useful for building documentation and the `latex` mode is useful for writing academic papers.

> **Warning.** Unicode handling in Windows Terminal
>
> When long results are displayed in Windows Terminal the more system utility is used by default to provide the scrolling through the results. This utility has incomplete support of Unicode, depending on the output data, in some cases it can display Unicode characters in garbled form.
>
> We suggest using the third-party less utility instead, that is installed by default along with the Git for Windows installation. It can be enabled the following way:
>
> ```
> .pager '"C:\Program Files\Git\usr\bin\less.exe" -R'
> ```

List of Output Formats

Mode	Description
`ascii`	Columns/rows delimited by 0x1F and 0x1E
`box`	Tables using unicode box-drawing characters
`csv`	Comma-separated values
`column`	Output in columns (See `.width`)
`duckbox`	Tables with extensive features (default)
`html`	HTML `<table>` code
`insert <TABLE>{:.language-sql .highlight}`	SQL insert statements for `<TABLE>{:.language-sql .highlight}`

Mode	Description
`json`	Results in a JSON array
`jsonlines`	Results in a NDJSON
`latex`	LaTeX tabular environment code
`line`	One value per line
`list`	Values delimited by |
`markdown`	Markdown table format
`quote`	Escape answers as for SQL
`table`	ASCII-art table
`tabs`	Tab-separated values
`tcl`	TCL list elements
`trash`	No output

Changing the Output Format

Use the vanilla `.mode` dot command to query the appearance currently in use.

```
.mode
```

```
current output mode: duckbox
```

Use the `.mode` dot command with an argument to set the output format.

```
.mode markdown
SELECT 'quacking intensifies' AS incoming_ducks;
```

```
|    incoming_ducks    |
|----------------------|
| quacking intensifies |
```

The output appearance can also be adjusted with the `.separator` command. If using an export mode that relies on a separator (`csv` or `tabs` for example), the separator will be reset when the mode is changed. For example, `.mode csv` will set the separator to a comma (`,`). Using `.separator "|"` will then convert the output to be pipe-separated.

```
.mode csv
SELECT 1 AS col_1, 2 AS col_2
UNION ALL
SELECT 10 AS col1, 20 AS col_2;
```

```
col_1,col_2
1,2
10,20
```

```
.separator "|"
SELECT 1 AS col_1, 2 AS col_2
UNION ALL
SELECT 10 AS col1, 20 AS col_2;
```

```
col_1|col_2
1|2
10|20
```

Paging

The CLI supports paging for large result sets using the `.pager` command. When enabled, results that exceed the terminal size are displayed in a pager (such as `less`) for easier navigation.

The pager has three modes:

- `automatic` (default) – The pager is triggered when the result exceeds the row or column threshold.
- on – The pager is always used for output.
- `off` – The pager is disabled.

```
.pager on
```

```
.pager off
```

```
.pager automatic
```

In automatic mode, the thresholds for triggering the pager can be configured:

```
.pager set_row_threshold 50
.pager set_column_threshold 5
```

A custom pager command can be set by passing it as an argument:

```
.pager less -RS
```

The default pager command can also be configured via the DUCKDB_PAGER or PAGER environment variables.

duckbox Mode

By default, DuckDB renders query results in `duckbox` mode, which is a feature-rich ASCII-art style output format.

The duckbox mode supports the `large_number_rendering` option, which allows human-readable rendering of large numbers. It has three levels:

- `off` – All numbers are printed using regular formatting.
- `footer` (default) – Large numbers are augmented with the human-readable format. Only applies to single-row results.
- `all` - All large numbers are replaced with the human-readable format.

See the following examples:

```
.large_number_rendering off
SELECT pi() * 1_000_000_000 AS x;
```

```
┌────────────────────┐
│         x          │
│       double       │
├────────────────────┤
│ 3141592653.589793  │
└────────────────────┘
```

```
.large_number_rendering footer
SELECT pi() * 1_000_000_000 AS x;
```

```
┌────────────────────┐
│         x          │
│       double       │
├────────────────────┤
│ 3141592653.589793  │
│  (3.14 billion)    │
└────────────────────┘
```

```
.large_number_rendering all
SELECT pi() * 1_000_000_000 AS x;
```

```
┌──────────────┐
│      x       │
│    double    │
├──────────────┤
│ 3.14 billion │
└──────────────┘
```

Editing

> The linenoise-based CLI editor is available for macOS, Linux and Windows.

DuckDB's CLI uses a line-editing library based on linenoise, which has shortcuts that are based on Emacs mode of readline. Below is a list of available commands. You can also view these shortcuts from within the CLI using `.help shortcuts`.

Moving

Key	Action
`Left`	Move back a character
`Right`	Move forward a character
Up	Move up a line. When on the first line, move to previous history entry
Down	Move down a line. When on last line, move to next history entry
`Home`	Move to beginning of buffer
`End`	Move to end of buffer
`Ctrl+Left`	Move back a word
`Ctrl+Right`	Move forward a word
`Ctrl+A`	Move to beginning of buffer
`Ctrl+B`	Move back a character
`Ctrl+E`	Move to end of buffer
`Ctrl+F`	Move forward a character
`Alt+Left`	Move back a word
`Alt+Right`	Move forward a word

History

Key	Action
`Ctrl+P`	Move to previous history entry
`Ctrl+N`	Move to next history entry
`Ctrl+R`	Search the history
`Ctrl+S`	Search the history
`Alt+<`	Move to first history entry
`Alt+>`	Move to last history entry
`Alt+N`	Search the history

Key	Action
`Alt+P`	Search the history

Changing Text

Key	Action
`Backspace`	Delete previous character
`Delete`	Delete next character
`Ctrl+D`	Delete next character. When buffer is empty, end editing
`Ctrl+H`	Delete previous character
`Ctrl+K`	Delete everything after the cursor
`Ctrl+T`	Swap current and next character
`Ctrl+U`	Delete all text
`Ctrl+W`	Delete previous word
`Alt+C`	Convert next word to titlecase
`Alt+D`	Delete next word
`Alt+L`	Convert next word to lowercase
`Alt+R`	Delete all text
`Alt+T`	Swap current and next word
`Alt+U`	Convert next word to uppercase
`Alt+Backspace`	Delete previous word
`Alt+\`	Delete spaces around cursor

Completing

Key	Action
`Tab`	Autocomplete. When autocompleting, cycle to next entry
`Shift+Tab`	When autocompleting, cycle to previous entry
`Esc+Esc`	When autocompleting, revert autocompletion

Miscellaneous

Key	Action
`Enter`	Execute query. If query is not complete, insert a newline at the end of the buffer
`Ctrl+J`	Execute query. If query is not complete, insert a newline at the end of the buffer
`Ctrl+C`	Cancel editing of current query
`Ctrl+G`	Cancel editing of current query

Key	Action
`Ctrl+L`	Clear screen
`Ctrl+O`	Cancel editing of current query
`Ctrl+X`	Insert a newline after the cursor
`Ctrl+Q`, then click	Move cursor to mouse click position
`Ctrl+Z`	Suspend CLI and return to shell, use `fg` to re-open

External Editor Mode

Use `.edit` or `\e` to open a query in an external text editor.

- When entered alone, it opens the previous command for editing.
- When used inside a multi-line command, it opens the current command in the editor.

The editor is taken from the first set environment variable among `DUCKDB_EDITOR`, `EDITOR` or `VISUAL` (in that order). If none are set, `vi` is used.

Using Read-Line

If you prefer, you can use `rlwrap` to use read-line directly with the shell. Then, use `Shift+Enter` to insert a newline and `Enter` to execute the query:

```
rlwrap --substitute-prompt="D " duckdb -batch
```

Friendly CLI

Along with our Friendly SQL, we provide **friendly CLI** features.

Dark/Light Mode

The CLI automatically detects whether the terminal is using a dark or light background and adjusts syntax highlighting colors accordingly. The mode can also be set manually using the `.highlight_mode` command:

```
.highlight_mode dark
```

```
.highlight_mode light
```

To use a mix of colors suitable for both dark and light backgrounds:

```
.highlight_mode mixed
```

8-Bit Colors

Since DuckDB v1.5, the CLI supports 8-bit colors corresponding to Xterm system colors:

```
.display_colors
```

```
darkred1 red darkred2 red3 red4 red1 brightred indianred1 ...
```

Dynamic Prompt

The default prompts are the following:

```
-- macOS / Linux
{max_length:40}{color:38,5,208}{color:bold}{setting:current_database_and_schema}{color:reset} D
-- Windows
{max_length:40}{color:green}{color:bold}{setting:current_database_and_schema}{color:reset} D
```

Return the Result of the Last Query Using _

You can use the _ (underscore) table to query the result of the last query:

```
SELECT 42 AS x;
```

```
┌───────┐
│   x   │
│ int32 │
├───────┤
│    42 │
└───────┘
```

```
FROM _;
```

```
┌───────┐
│   x   │
│ int32 │
├───────┤
│    42 │
└───────┘
```

If the last query did not return a result (e.g., because it performed an update operation), the CLI throws an error:

```
Binder Error:
Failed to query last result "_": no result available
```

Safe Mode

The DuckDB CLI client supports "safe mode". In safe mode, the CLI is prevented from accessing external files other than the database file that it was initially connected to and prevented from interacting with the host file system.

This has the following effects:

- The following dot commands are disabled:
  - `.cd`
  - `.excel`
  - `.import`
  - `.log`
  - `.once`
  - `.open`
  - `.output`
  - `.read`
  - `.sh`
  - `.system`
- Auto-complete no longer scans the file system for files to suggest as auto-complete targets.
- The `getenv` function is disabled.
- The `enable_external_access` option is set to `false`. This implies that:

- ATTACH cannot attach to a database in a file.
- COPY cannot read to or write from files.
- Functions such as `read_csv`, `read_parquet`, `read_json`, etc. cannot read from an external source.

Once safe mode is activated, it cannot be deactivated in the same DuckDB CLI session.

For more information on running DuckDB in secure environments, see the "Securing DuckDB" page.

Autocomplete

The shell offers context-aware autocomplete of SQL queries through the `autocomplete` extension. autocomplete is triggered by pressing `Tab`.

Multiple autocomplete suggestions can be present. You can cycle forwards through the suggestions by repeatedly pressing `Tab`, or `Shift+Tab` to cycle backwards. autocompletion can be reverted by pressing ESC twice.

The shell autocompletes four different groups:

- Keywords
- Table names and table functions
- Column names and scalar functions
- File names

The shell looks at the position in the SQL statement to determine which of these autocompletions to trigger. For example:

```
SELECT s

student_id

SELECT student_id F

FROM

SELECT student_id FROM g

grades

SELECT student_id FROM 'd

'data/

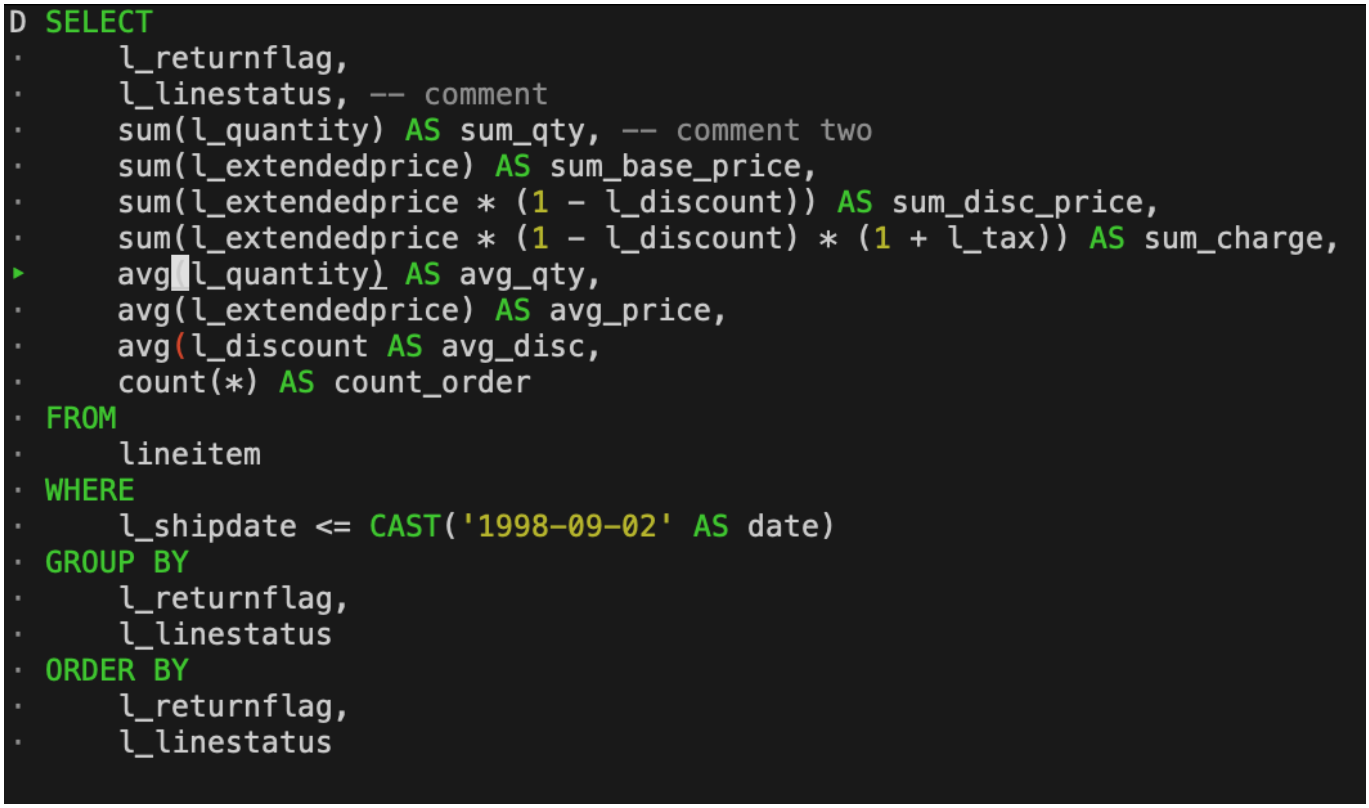
SELECT student_id FROM 'data/

'data/grades.csv
```

Syntax Highlighting

> Syntax highlighting in the CLI is currently only available for macOS and Linux.

SQL queries that are written in the shell are automatically highlighted using syntax highlighting.



There are several components of a query that are highlighted in different colors. The colors can be configured using dot commands. Syntax highlighting can also be disabled entirely using the `.highlight off` command.

Below is a list of components that can be configured.

Type	Command	Default color
Keywords	`.keyword`	`green`
Constants and literals	`.constant`	`yellow`
Comments	`.comment`	`brightblack`
Errors	`.error`	`red`
Continuation	`.cont`	`brightblack`
Continuation (Selected)	`.cont_sel`	`green`

The components can be configured using either a supported color name (e.g., `.keyword red`), or by directly providing a terminal code to use for rendering (e.g., `.keywordcode \033[31m`). Below is a list of supported color names and their corresponding terminal codes.

Color	Terminal code
red	`\033[31m`
green	`\033[32m`
yellow	`\033[33m`
blue	`\033[34m`
magenta	`\033[35m`
cyan	`\033[36m`
white	`\033[37m`

Color	Terminal code
brightblack	`\033[90m`
brightred	`\033[91m`
brightgreen	`\033[92m`
brightyellow	`\033[93m`
brightblue	`\033[94m`
brightmagenta	`\033[95m`
brightcyan	`\033[96m`
brightwhite	`\033[97m`

For example, here is an alternative set of syntax highlighting colors:

```
.keyword brightred
.constant brightwhite
.comment cyan
.error yellow
.cont blue
.cont_sel brightblue
```

If you wish to start up the CLI with a different set of colors every time, you can place these commands in the `~/.duckdbrc` file that is loaded on start-up of the CLI.

Error Highlighting

The shell has support for highlighting certain errors. In particular, mismatched brackets and unclosed quotes are highlighted in red (or another color if specified). This highlighting is automatically disabled for large queries. In addition, it can be disabled manually using the `.render_errors off` command.

Known Issues

Incorrect Memory Values on Old Linux Distributions and WSL 2

On Windows Subsystem for Linux 2 (WSL2), when querying the `max_memory` or `memory_limit` from the `duckdb_settings`, the values may be inaccurate on certain Ubuntu versions (e.g., 20.04 and 24.04). The issue also occurs on older distributions such as Red Hat Enterprise Linux 8 (RHEL 8):

Example:

```
FROM duckdb_settings() WHERE name LIKE '%mem%';
```

The output contains values larger than 1000 PiB:

name varchar	value varchar	description varchar	input_type varchar	scope varchar
max_memory	1638.3 PiB	The maximum memory of the system (e.g. 1GB)	VARCHAR	GLOBAL
memory_limit	1638.3 PiB	The maximum memory of the system (e.g. 1GB)	VARCHAR	GLOBAL

Go Client

> Installation To use the DuckDB Go client, visit the Go installation page.
>
> The latest stable version of the DuckDB Go client is {% if site.current_duckdb_go_version != "" %}{{ site.current_duckdb_go_version }}{% else %}{{ site.lts_duckdb_go_version }}{% endif %}.

The DuckDB Go client, duckdb-go, allows using DuckDB via the `database/sql` interface. For examples on how to use this interface, see the official documentation and tutorial.

Installation

To install the `duckdb-go` client, run:

```
go get github.com/duckdb/duckdb-go/v2
```

Importing

To import the DuckDB Go package, add the following entries to your imports:

```
import (
    "database/sql"
    _ "github.com/duckdb/duckdb-go/v2"
)
```

Appender

The DuckDB Go client supports the DuckDB Appender API for bulk inserts. You can obtain a new Appender by supplying a DuckDB connection to `NewAppenderFromConn()`. For example:

```
connector, err := duckdb.NewConnector("test.db", nil)
if err != nil {
    ...
}
conn, err := connector.Connect(context.Background())
if err != nil {
    ...
}
defer conn.Close()

// Retrieve appender from connection (note that you have to create the table 'test' beforehand).
appender, err := NewAppenderFromConn(conn, "", "test")
if err != nil {
    ...
}
defer appender.Close()

err = appender.AppendRow(...)
if err != nil {
    ...
```

```
}

// Optional, if you want to access the appended rows immediately.
err = appender.Flush()
if err != nil {
    ...
}
```

Examples

Simple Example

An example for using the Go API is as follows:

```
package main

import (
    "database/sql"
    "errors"
    "fmt"
    "log"

    _ "github.com/duckdb/duckdb-go/v2"
)

func main() {
    db, err := sql.Open("duckdb", "")
    if err != nil {
        log.Fatal(err)
    }
    defer db.Close()

    _, err = db.Exec(` CREATE TABLE people (id INTEGER, name VARCHAR)`)
    if err != nil {
        log.Fatal(err)
    }
    _, err = db.Exec(` INSERT INTO people VALUES (42, 'John')`)
    if err != nil {
        log.Fatal(err)
    }

    var (
        id   int
        name string
    )
    row := db.QueryRow(` SELECT id, name FROM people`)
    err = row.Scan(&id, &name)
    if errors.Is(err, sql.ErrNoRows) {
        log.Println("no rows")
    } else if err != nil {
        log.Fatal(err)
    }

    fmt.Printf("id: %d, name: %s\n", id, name)
}
```

More Examples

For more examples, see the examples in the duckdb-go repository.

Acknowledgements

We would like to thank Marc Boeker for the initial implementation of the DuckDB Go client.

Java (JDBC) Client

> Installation To use the DuckDB Java (JDBC) client, visit the Java installation page.
>
> The latest stable version of the DuckDB Java (JDBC) client is {% if site.current_duckdb_java_short_version != "" %}{{ site.current_duckdb_java_short_version }}{% else %}{{ site.lts_duckdb_java_short_version }}{% endif %}.

Installation

The DuckDB Java JDBC API can be installed from Maven Central. Please see the installation page for details.

Basic API Usage

DuckDB's JDBC API implements the main parts of the standard Java Database Connectivity (JDBC) API, version 4.1. Describing JDBC is beyond the scope of this page, see the official documentation for details. Below we focus on the DuckDB-specific parts.

Refer to the externally hosted API Reference for more information about our extensions to the JDBC specification, or the below Arrow Methods.

Startup & Shutdown

In JDBC, database connections are created through the standard `java.sql.DriverManager` class. The driver should auto-register in the `DriverManager`, if that does not work for some reason, you can enforce registration using the following statement:

```
Class.forName("org.duckdb.DuckDBDriver");
```

To create a DuckDB connection, call `DriverManager` with the `jdbc:duckdb:` JDBC URL prefix, like so:

```
import java.sql.Connection;
import java.sql.DriverManager;

Connection conn = DriverManager.getConnection("jdbc:duckdb:");
```

To use DuckDB-specific features such as the Appender, cast the object to a `DuckDBConnection`:

```
import java.sql.DriverManager;
import org.duckdb.DuckDBConnection;

DuckDBConnection conn = (DuckDBConnection) DriverManager.getConnection("jdbc:duckdb:");
```

When using the `jdbc:duckdb:` URL alone, an **in-memory database** is created. Note that for an in-memory database no data is persisted to disk (i.e., all data is lost when you exit the Java program). If you would like to access or create a persistent database, append its file name after the path. For example, if your database is stored in `/tmp/my_database`, use the JDBC URL `jdbc:duckdb:/tmp/my_database` to create a connection to it.

It is possible to open a DuckDB database file in **read-only** mode. This is for example useful if multiple Java processes want to read the same database file at the same time. To open an existing database file in read-only mode, set the connection property `duckdb.read_only` like so:

```
Properties readOnlyProperty = new Properties();
readOnlyProperty.setProperty("duckdb.read_only", "true");
Connection conn = DriverManager.getConnection("jdbc:duckdb:/tmp/my_database", readOnlyProperty);
```

Additional connections can be created using the `DriverManager`. A more efficient mechanism is to call the `DuckDBConnection#duplicate()` method:

```
Connection conn2 = ((DuckDBConnection) conn).duplicate();
```

Multiple connections are allowed, but mixing read-write and read-only connections is unsupported.

Configuring Connections

Configuration options can be provided to change different settings of the database system. Note that many of these settings can be changed later on using PRAGMA statements as well.

```
Properties connectionProperties = new Properties();
connectionProperties.setProperty("temp_directory", "/path/to/temp/dir/");
Connection conn = DriverManager.getConnection("jdbc:duckdb:/tmp/my_database", connectionProperties);
```

Querying

DuckDB supports the standard JDBC methods to send queries and retrieve result sets. First a `Statement` object has to be created from the `Connection`, this object can then be used to send queries using `execute` and `executeQuery`. `execute()` is meant for queries where no results are expected like `CREATE TABLE` or `UPDATE` etc. and `executeQuery()` is meant to be used for queries that produce results (e.g., `SELECT`). Below two examples. See also the JDBC `Statement` and `ResultSet` documentations.

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.ResultSet;
import java.sql.SQLException;
import java.sql.Statement;

Connection conn = DriverManager.getConnection("jdbc:duckdb:");

// create a table
Statement stmt = conn.createStatement();
stmt.execute("CREATE TABLE items (item VARCHAR, value DECIMAL(10, 2), count INTEGER)");
// insert two items into the table
stmt.execute("INSERT INTO items VALUES ('jeans', 20.0, 1), ('hammer', 42.2, 2)");

try (ResultSet rs = stmt.executeQuery("SELECT * FROM items")) {
    while (rs.next()) {
        System.out.println(rs.getString(1));
        System.out.println(rs.getInt(3));
    }
}
stmt.close();
```

```
jeans
1
hammer
2
```

DuckDB also supports prepared statements as per the JDBC API:

```
import java.sql.PreparedStatement;

try (PreparedStatement stmt = conn.prepareStatement("INSERT INTO items VALUES (?, ?, ?);")) {
    stmt.setString(1, "chainsaw");
    stmt.setDouble(2, 500.0);
    stmt.setInt(3, 42);
    stmt.execute();
```

```
    // more calls to execute() possible
}
```

> **Warning.** Do *not* use prepared statements to insert large amounts of data into DuckDB. See the data import documentation for better options.

Arrow Methods

Refer to the API Reference for type signatures

Arrow Export The following demonstrates exporting an arrow stream and consuming it using the java arrow bindings

```
import org.apache.arrow.memory.RootAllocator;
import org.apache.arrow.vector.ipc.ArrowReader;
import org.duckdb.DuckDBResultSet;

try (var conn = DriverManager.getConnection("jdbc:duckdb:");
    var stmt = conn.prepareStatement("SELECT * FROM generate_series(2000)");
    var resultset = (DuckDBResultSet) stmt.executeQuery();
    var allocator = new RootAllocator()) {
    try (var reader = (ArrowReader) resultset.arrowExportStream(allocator, 256)) {
        while (reader.loadNextBatch()) {
            System.out.println(reader.getVectorSchemaRoot().getVector("generate_series"));
        }
    }
    stmt.close();
}
```

Arrow Import The following demonstrates consuming an Arrow stream from the Java Arrow bindings.

```
import org.apache.arrow.memory.RootAllocator;
import org.apache.arrow.vector.ipc.ArrowReader;
import org.duckdb.DuckDBConnection;

// Arrow binding
try (var allocator = new RootAllocator();
     ArrowStreamReader reader = null; // should not be null of course
     var arrow_array_stream = ArrowArrayStream.allocateNew(allocator)) {
    Data.exportArrayStream(allocator, reader, arrow_array_stream);

    // DuckDB setup
    try (var conn = (DuckDBConnection) DriverManager.getConnection("jdbc:duckdb:")) {
        conn.registerArrowStream("asdf", arrow_array_stream);

        // run a query
        try (var stmt = conn.createStatement();
             var rs = (DuckDBResultSet) stmt.executeQuery("SELECT count(*) FROM asdf")) {
            while (rs.next()) {
                System.out.println(rs.getInt(1));
            }
        }
    }
}
```

Streaming Results

Result streaming is opt-in in the JDBC driver – by setting the `jdbc_stream_results` config to `true` before running a query. The easiest way to do that is to pass it in the `Properties` object.

```
Properties props = new Properties();
props.setProperty(DuckDBDriver.JDBC_STREAM_RESULTS, String.valueOf(true));

Connection conn = DriverManager.getConnection("jdbc:duckdb:", props);
```

Appender

The Appender is available in the DuckDB JDBC driver via the `org.duckdb.DuckDBAppender` class. The constructor of the class requires the schema name and the table name it is applied to. The Appender is flushed when the `close()` method is called.

Example:

```
import java.sql.DriverManager;
import java.sql.Statement;
import org.duckdb.DuckDBConnection;

DuckDBConnection conn = (DuckDBConnection) DriverManager.getConnection("jdbc:duckdb:");
try (var stmt = conn.createStatement()) {
    stmt.execute("CREATE TABLE tbl (x BIGINT, y FLOAT, s VARCHAR)"
);

// using try-with-resources to automatically close the appender at the end of the scope
try (var appender = conn.createAppender(DuckDBConnection.DEFAULT_SCHEMA, "tbl")) {
    appender.beginRow();
    appender.append(10);
    appender.append(3.2);
    appender.append("hello");
    appender.endRow();
    appender.beginRow();
    appender.append(20);
    appender.append(-8.1);
    appender.append("world");
    appender.endRow();
}
```

Batch Writer

The DuckDB JDBC driver offers batch write functionality. The batch writer supports prepared statements to mitigate the overhead of query parsing.

> The preferred method for bulk inserts is to use the Appender due to its higher performance. However, when using the Appender is not possible, the batch writer is available as alternative.

Batch Writer with Prepared Statements

```
import java.sql.DriverManager;
import java.sql.PreparedStatement;
import org.duckdb.DuckDBConnection;

DuckDBConnection conn = (DuckDBConnection) DriverManager.getConnection("jdbc:duckdb:");
PreparedStatement stmt = conn.prepareStatement("INSERT INTO test (x, y, z) VALUES (?, ?, ?);");

stmt.setObject(1, 1);
```

```
stmt.setObject(2, 2);
stmt.setObject(3, 3);
stmt.addBatch();

stmt.setObject(1, 4);
stmt.setObject(2, 5);
stmt.setObject(3, 6);
stmt.addBatch();

stmt.executeBatch();
stmt.close();
```

Batch Writer with Vanilla Statements The batch writer also supports vanilla SQL statements:

```
import java.sql.DriverManager;
import java.sql.Statement;
import org.duckdb.DuckDBConnection;

DuckDBConnection conn = (DuckDBConnection) DriverManager.getConnection("jdbc:duckdb:");
Statement stmt = conn.createStatement();

stmt.execute("CREATE TABLE test (x INTEGER, y INTEGER, z INTEGER)");

stmt.addBatch("INSERT INTO test (x, y, z) VALUES (1, 2, 3);");
stmt.addBatch("INSERT INTO test (x, y, z) VALUES (4, 5, 6);");

stmt.executeBatch();
stmt.close();
```

Troubleshooting

Driver Class Not Found

If the Java application is unable to find the DuckDB driver, it may throw the following error:

```
Exception in thread "main" java.sql.SQLException: No suitable driver found for jdbc:duckdb:
    at java.sql/java.sql.DriverManager.getConnection(DriverManager.java:706)
    at java.sql/java.sql.DriverManager.getConnection(DriverManager.java:252)
    ...
```

And when trying to load the class manually, it may result in this error:

```
Exception in thread "main" java.lang.ClassNotFoundException: org.duckdb.DuckDBDriver
    at java.base/jdk.internal.loader.BuiltinClassLoader.loadClass(BuiltinClassLoader.java:641)
    at java.base/jdk.internal.loader.ClassLoaders$AppClassLoader.loadClass(ClassLoaders.java:188)
    at java.base/java.lang.ClassLoader.loadClass(ClassLoader.java:520)
    at java.base/java.lang.Class.forName0(Native Method)
    at java.base/java.lang.Class.forName(Class.java:375)
    ...
```

These errors stem from the DuckDB Maven/Gradle dependency not being detected. To ensure that it is detected, force refresh the Maven configuration in your IDE.

Node.js (Neo)

Node.js Client (Neo)

> Installation To use the DuckDB Node.js client, visit the Node.js installation page.
>
> The latest stable version of the DuckDB Node.js (Neo) client is {% if site.current_duckdb_node_neo_version != "" %}{{ site.current_duckdb_node_neo_version }}{% else %}{{ site.lts_duckdb_node_neo_version }}{% endif %}.

An API for using DuckDB in Node.js.

The primary package, @duckdb/node-api, is a high-level API meant for applications. It depends on low-level bindings that adhere closely to DuckDB's C API, available separately as @duckdb/node-bindings.

Roadmap

Some features are not yet complete:

- Binding and appending the MAP and UNION data types
- Appending default values row-by-row
- User-defined types & functions
- Profiling info
- Table description
- APIs for Arrow

See the issues list on GitHub for the most up-to-date roadmap.

Platforms

The Node.js (Neo) client supports the following platforms:

- `linux_amd64`
- `linux_arm64`
- `osx_amd64`
- `osx_arm64`
- `windows_amd64`

The `windows_arm64` platform is currently not supported.

Examples

Get Basic Information

```
import duckdb from '@duckdb/node-api';

console.log(duckdb.version());

console.log(duckdb.configurationOptionDescriptions());
```

Connect

```
import { DuckDBConnection } from '@duckdb/node-api';

const connection = await DuckDBConnection.create();
```

This uses the default instance. For advanced usage, you can create instances explicitly.

Create Instance

```
import { DuckDBInstance } from '@duckdb/node-api';
```

Create with an in-memory database:

```
const instance = await DuckDBInstance.create(':memory:');
```

Equivalent to the above:

```
const instance = await DuckDBInstance.create();
```

Read from and write to a database file, which is created if needed:

```
const instance = await DuckDBInstance.create('my_duckdb.db');
```

Set configuration options:

```
const instance = await DuckDBInstance.create('my_duckdb.db', {
  threads: '4'
});
```

Instance Cache

Multiple instances in the same process should not attach the same database.

To prevent this, an instance cache can be used:

```
const instance = await DuckDBInstance.fromCache('my_duckdb.db');
```

This uses the default instance cache. For advanced usage, you can create instance caches explicitly:

```
import { DuckDBInstanceCache } from '@duckdb/node-api';

const cache = new DuckDBInstanceCache();
const instance = await cache.getOrCreateInstance('my_duckdb.db');
```

Connect to Instance

```
const connection = await instance.connect();
```

Disconnect

Connections will be disconnected automatically soon after their reference is dropped, but you can also disconnect explicitly if and when you want:

```
connection.disconnectSync();
```

or, equivalently:

```
connection.closeSync();
```

Run SQL

```
const result = await connection.run('from test_all_types()');
```

Parameterize SQL

```
const prepared = await connection.prepare('select $1, $2, $3');
prepared.bindVarchar(1, 'duck');
prepared.bindInteger(2, 42);
prepared.bindList(3, listValue([10, 11, 12]), LIST(INTEGER));
const result = await prepared.run();
```

or:

```
const prepared = await connection.prepare('select $a, $b, $c');
prepared.bind({
  'a': 'duck',
  'b': 42,
  'c': listValue([10, 11, 12]),
}, {
  'a': VARCHAR,
  'b': INTEGER,
  'c': LIST(INTEGER),
});
const result = await prepared.run();
```

or even:

```
const result = await connection.run('select $a, $b, $c', {
  'a': 'duck',
  'b': 42,
  'c': listValue([10, 11, 12]),
}, {
  'a': VARCHAR,
  'b': INTEGER,
  'c': LIST(INTEGER),
});
```

Unspecified types will be inferred:

```
const result = await connection.run('select $a, $b, $c', {
  'a': 'duck',
  'b': 42,
  'c': listValue([10, 11, 12]),
});
```

Specifying Values

Values of many data types are represented using one of the JS primitives `boolean`, `number`, `bigint`, or `string`. Also, any type can have `null` values.

Values of some data types need to be constructed using special functions. These are:

Type	Function
ARRAY	arrayValue
BIT	bitValue
BLOB	blobValue

Type	Function
DATE	dateValue
DECIMAL	decimalValue
INTERVAL	intervalValue
LIST	listValue
MAP	mapValue
STRUCT	structValue
TIME	timeValue
TIMETZ	timeTZValue
TIMESTAMP	timestampValue
TIMESTAMPTZ	timestampTZValue
TIMESTAMP_S	timestampSecondsValue
TIMESTAMP_MS	timestampMillisValue
TIMESTAMP_NS	timestampNanosValue
UNION	unionValue
UUID	uuidValue

Stream Results

Streaming results evaluate lazily when rows are read.

```
const result = await connection.stream('from range(10_000)');
```

Inspect Result Metadata

Get column names and types:

```
const columnNames = result.columnNames();
const columnTypes = result.columnTypes();
```

Read Result Data

Run and read all data:

```
const reader = await connection.runAndReadAll('from test_all_types()');
const rows = reader.getRows();
// OR: const columns = reader.getColumns();
```

Stream and read up to (at least) some number of rows:

```
const reader = await connection.streamAndReadUntil(
  'from range(5000)',
  1000
);
const rows = reader.getRows();
// rows.length === 2048. (Rows are read in chunks of 2048.)
```

Read rows incrementally:

```
const reader = await connection.streamAndRead('from range(5000)');
reader.readUntil(2000);
// reader.currentRowCount === 2048 (Rows are read in chunks of 2048.)
// reader.done === false
reader.readUntil(4000);
// reader.currentRowCount === 4096
// reader.done === false
reader.readUntil(6000);
// reader.currentRowCount === 5000
// reader.done === true
```

Get Result Data

Result data can be retrieved in a variety of forms:

```
const reader = await connection.runAndReadAll(
  'from range(3) select range::int as i, 10 + i as n'
);

const rows = reader.getRows();
// [ [0, 10], [1, 11], [2, 12] ]

const rowObjects = reader.getRowObjects();
// [ { i: 0, n: 10 }, { i: 1, n: 11 }, { i: 2, n: 12 } ]

const columns = reader.getColumns();
// [ [0, 1, 2], [10, 11, 12] ]

const columnsObject = reader.getColumnsObject();
// { i: [0, 1, 2], n: [10, 11, 12] }
```

Convert Result Data

By default, data values that cannot be represented as JS built-ins are returned as specialized JS objects; see `Inspect Data Values` below.

To retrieve data in a different form, such as JS built-ins or values that can be losslessly serialized to JSON, use the `JS` or `Json` forms of the above result data methods.

Custom converters can be supplied as well. See the implementations of JSDuckDBValueConverter and JsonDuckDBValueConverters for how to do this.

Examples (using the `Json` forms):

```
const reader = await connection.runAndReadAll(
  'from test_all_types() select bigint, date, interval limit 2'
);

const rows = reader.getRowsJson();
// [
//   [
//     "-9223372036854775808",
//     "5877642-06-25 (BC)",
//     { "months": 0, "days": 0, "micros": "0" }
//   ],
//   [
//     "9223372036854775807",
//     "5881580-07-10",
//     { "months": 999, "days": 999, "micros": "999999999" }
```

```
//   ]
// ]

const rowObjects = reader.getRowObjectsJson();
// [
//   {
//     "bigint": "-9223372036854775808",
//     "date": "5877642-06-25 (BC)",
//     "interval": { "months": 0, "days": 0, "micros": "0" }
//   },
//   {
//     "bigint": "9223372036854775807",
//     "date": "5881580-07-10",
//     "interval": { "months": 999, "days": 999, "micros": "999999999" }
//   }
// ]

const columns = reader.getColumnsJson();
// [
//   [ "-9223372036854775808", "9223372036854775807" ],
//   [ "5877642-06-25 (BC)", "5881580-07-10" ],
//   [
//     { "months": 0, "days": 0, "micros": "0" },
//     { "months": 999, "days": 999, "micros": "999999999" }
//   ]
// ]

const columnsObject = reader.getColumnsObjectJson();
// {
//   "bigint": [ "-9223372036854775808", "9223372036854775807" ],
//   "date": [ "5877642-06-25 (BC)", "5881580-07-10" ],
//   "interval": [
//     { "months": 0, "days": 0, "micros": "0" },
//     { "months": 999, "days": 999, "micros": "999999999" }
//   ]
// }
```

These methods handle nested types as well:

```
const reader = await connection.runAndReadAll(
  'from test_all_types() select int_array, struct, map, "union" limit 2'
);

const rows = reader.getRowsJson();
// [
//   [
//     [],
//     { "a": null, "b": null },
//     [],
//     { "tag": "name", "value": "Frank" }
//   ],
//   [
//     [ 42, 999, null, null, -42],
//     { "a": 42, "b": "🦆🦆🦆🦆🦆🦆" },
//     [
//       { "key": "key1", "value": "🦆🦆🦆🦆🦆🦆" },
//       { "key": "key2", "value": "goose" }
//     ],
//     { "tag": "age", "value": 5 }
//   ]
```

```
// ]

const rowObjects = reader.getRowObjectsJson();
// [
//   {
//     "int_array": [],
//     "struct": { "a": null, "b": null },
//     "map": [],
//     "union": { "tag": "name", "value": "Frank" }
//   },
//   {
//     "int_array": [ 42, 999, null, null, -42 ],
//     "struct": { "a": 42, "b": "🦆🦆🦆🦆🦆" },
//     "map": [
//       { "key": "key1", "value": "🦆🦆🦆🦆🦆" },
//       { "key": "key2", "value": "goose" }
//     ],
//     "union": { "tag": "age", "value": 5 }
//   }
// ]

const columns = reader.getColumnsJson();
// [
//   [
//     [],
//     [42, 999, null, null, -42]
//   ],
//   [
//     { "a": null, "b": null },
//     { "a": 42, "b": "🦆🦆🦆🦆🦆" }
//   ],
//   [
//     [],
//     [
//       { "key": "key1", "value": "🦆🦆🦆🦆🦆" },
//       { "key": "key2", "value": "goose"}
//     ]
//   ],
//   [
//     { "tag": "name", "value": "Frank" },
//     { "tag": "age", "value": 5 }
//   ]
// ]

const columnsObject = reader.getColumnsObjectJson();
// {
//   "int_array": [
//     [],
//     [42, 999, null, null, -42]
//   ],
//   "struct": [
//     { "a": null, "b": null },
//     { "a": 42, "b": "🦆🦆🦆🦆🦆" }
//   ],
//   "map": [
//     [],
//     [
//       { "key": "key1", "value": "🦆🦆🦆🦆🦆" },
//       { "key": "key2", "value": "goose" }
//     ]
```

```
//   ],
//   "union": [
//     { "tag": "name", "value": "Frank" },
//     { "tag": "age", "value": 5 }
//   ]
// }
```

Column names and types can also be serialized to JSON:

```
const columnNamesAndTypes = reader.columnNamesAndTypesJson();
// {
//   "columnNames": [
//     "int_array",
//     "struct",
//     "map",
//     "union"
//   ],
//   "columnTypes": [
//     {
//       "typeId": 24,
//       "valueType": {
//         "typeId": 4
//       }
//     },
//     {
//       "typeId": 25,
//       "entryNames": [
//         "a",
//         "b"
//       ],
//       "entryTypes": [
//         {
//           "typeId": 4
//         },
//         {
//           "typeId": 17
//         }
//       ]
//     },
//     {
//       "typeId": 26,
//       "keyType": {
//         "typeId": 17
//       },
//       "valueType": {
//         "typeId": 17
//       }
//     },
//     {
//       "typeId": 28,
//       "memberTags": [
//         "name",
//         "age"
//       ],
//       "memberTypes": [
//         {
//           "typeId": 17
//         },
//         {
//           "typeId": 3
```

```
//         }
//       ]
//     }
//   ]
// }

const columnNameAndTypeObjects = reader.columnNameAndTypeObjectsJson();
// [
//   {
//     "columnName": "int_array",
//     "columnType": {
//       "typeId": 24,
//       "valueType": {
//         "typeId": 4
//       }
//     }
//   },
//   {
//     "columnName": "struct",
//     "columnType": {
//       "typeId": 25,
//       "entryNames": [
//         "a",
//         "b"
//       ],
//       "entryTypes": [
//         {
//           "typeId": 4
//         },
//         {
//           "typeId": 17
//         }
//       ]
//     }
//   },
//   {
//     "columnName": "map",
//     "columnType": {
//       "typeId": 26,
//       "keyType": {
//         "typeId": 17
//       },
//       "valueType": {
//         "typeId": 17
//       }
//     }
//   },
//   {
//     "columnName": "union",
//     "columnType": {
//       "typeId": 28,
//       "memberTags": [
//         "name",
//         "age"
//       ],
//       "memberTypes": [
//         {
//           "typeId": 17
//         },
//         {
```

```
//           "typeId": 3
//         }
//       ]
//     }
//   }
// ]
```

Fetch Chunks

Fetch all chunks:

```
const chunks = await result.fetchAllChunks();
```

Fetch one chunk at a time:

```
const chunks = [];
while (true) {
  const chunk = await result.fetchChunk();
  // Last chunk will have zero rows.
  if (chunk.rowCount === 0) {
    break;
  }
  chunks.push(chunk);
}
```

For materialized (non-streaming) results, chunks can be read by index:

```
const rowCount = result.rowCount;
const chunkCount = result.chunkCount;
for (let i = 0; i < chunkCount; i++) {
  const chunk = result.getChunk(i);
  // ...
}
```

Get chunk data:

```
const rows = chunk.getRows();

const rowObjects = chunk.getRowObjects(result.deduplicatedColumnNames());

const columns = chunk.getColumns();

const columnsObject =
  chunk.getColumnsObject(result.deduplicatedColumnNames());
```

Get chunk data (one value at a time)

```
const columns = [];
const columnCount = chunk.columnCount;
for (let columnIndex = 0; columnIndex < columnCount; columnIndex++) {
  const columnValues = [];
  const columnVector = chunk.getColumnVector(columnIndex);
  const itemCount = columnVector.itemCount;
  for (let itemIndex = 0; itemIndex < itemCount; itemIndex++) {
    const value = columnVector.getItem(itemIndex);
    columnValues.push(value);
  }
  columns.push(columnValues);
}
```

Inspect Data Types

```
import { DuckDBTypeId } from '@duckdb/node-api';

if (columnType.typeId === DuckDBTypeId.ARRAY) {
  const arrayValueType = columnType.valueType;
  const arrayLength = columnType.length;
}

if (columnType.typeId === DuckDBTypeId.DECIMAL) {
  const decimalWidth = columnType.width;
  const decimalScale = columnType.scale;
}

if (columnType.typeId === DuckDBTypeId.ENUM) {
  const enumValues = columnType.values;
}

if (columnType.typeId === DuckDBTypeId.LIST) {
  const listValueType = columnType.valueType;
}

if (columnType.typeId === DuckDBTypeId.MAP) {
  const mapKeyType = columnType.keyType;
  const mapValueType = columnType.valueType;
}

if (columnType.typeId === DuckDBTypeId.STRUCT) {
  const structEntryNames = columnType.names;
  const structEntryTypes = columnType.valueTypes;
}

if (columnType.typeId === DuckDBTypeId.UNION) {
  const unionMemberTags = columnType.memberTags;
  const unionMemberTypes = columnType.memberTypes;
}

// For the JSON type (https://duckdb.org/docs/current/data/json/json_type)
if (columnType.alias === 'JSON') {
  const json = JSON.parse(columnValue);
}
```

Every type implements toString. The result is both human-friendly and readable by DuckDB in an appropriate expression.

```
const typeString = columnType.toString();
```

Inspect Data Values

```
import { DuckDBTypeId } from '@duckdb/node-api';

if (columnType.typeId === DuckDBTypeId.ARRAY) {
  const arrayItems = columnValue.items; // array of values
  const arrayString = columnValue.toString();
}

if (columnType.typeId === DuckDBTypeId.BIT) {
  const bools = columnValue.toBools(); // array of booleans
  const bits = columnValue.toBits(); // array of 0s and 1s
  const bitString = columnValue.toString(); // string of '0's and '1's
```

```
}

if (columnType.typeId === DuckDBTypeId.BLOB) {
  const blobBytes = columnValue.bytes; // Uint8Array
  const blobString = columnValue.toString();
}

if (columnType.typeId === DuckDBTypeId.DATE) {
  const dateDays = columnValue.days;
  const dateString = columnValue.toString();
  const { year, month, day } = columnValue.toParts();
}

if (columnType.typeId === DuckDBTypeId.DECIMAL) {
  const decimalWidth = columnValue.width;
  const decimalScale = columnValue.scale;
  // Scaled-up value. Represented number is value/(10^scale).
  const decimalValue = columnValue.value; // bigint
  const decimalString = columnValue.toString();
  const decimalDouble = columnValue.toDouble();
}

if (columnType.typeId === DuckDBTypeId.INTERVAL) {
  const intervalMonths = columnValue.months;
  const intervalDays = columnValue.days;
  const intervalMicros = columnValue.micros; // bigint
  const intervalString = columnValue.toString();
}

if (columnType.typeId === DuckDBTypeId.LIST) {
  const listItems = columnValue.items; // array of values
  const listString = columnValue.toString();
}

if (columnType.typeId === DuckDBTypeId.MAP) {
  const mapEntries = columnValue.entries; // array of { key, value }
  const mapString = columnValue.toString();
}

if (columnType.typeId === DuckDBTypeId.STRUCT) {
  // { name1: value1, name2: value2, ... }
  const structEntries = columnValue.entries;
  const structString = columnValue.toString();
}

if (columnType.typeId === DuckDBTypeId.TIMESTAMP_MS) {
  const timestampMillis = columnValue.milliseconds; // bigint
  const timestampMillisString = columnValue.toString();
}

if (columnType.typeId === DuckDBTypeId.TIMESTAMP_NS) {
  const timestampNanos = columnValue.nanoseconds; // bigint
  const timestampNanosString = columnValue.toString();
}

if (columnType.typeId === DuckDBTypeId.TIMESTAMP_S) {
  const timestampSecs = columnValue.seconds; // bigint
  const timestampSecsString = columnValue.toString();
}
```

```
if (columnType.typeId === DuckDBTypeId.TIMESTAMP_TZ) {
  const timestampTZMicros = columnValue.micros; // bigint
  const timestampTZString = columnValue.toString();
  const {
    date: { year, month, day },
    time: { hour, min, sec, micros },
  } = columnValue.toParts();
}

if (columnType.typeId === DuckDBTypeId.TIMESTAMP) {
  const timestampMicros = columnValue.micros; // bigint
  const timestampString = columnValue.toString();
  const {
    date: { year, month, day },
    time: { hour, min, sec, micros },
  } = columnValue.toParts();
}

if (columnType.typeId === DuckDBTypeId.TIME_TZ) {
  const timeTZMicros = columnValue.micros; // bigint
  const timeTZOffset = columnValue.offset;
  const timeTZString = columnValue.toString();
  const {
    time: { hour, min, sec, micros },
    offset,
  } = columnValue.toParts();
}

if (columnType.typeId === DuckDBTypeId.TIME) {
  const timeMicros = columnValue.micros; // bigint
  const timeString = columnValue.toString();
  const { hour, min, sec, micros } = columnValue.toParts();
}

if (columnType.typeId === DuckDBTypeId.UNION) {
  const unionTag = columnValue.tag;
  const unionValue = columnValue.value;
  const unionValueString = columnValue.toString();
}

if (columnType.typeId === DuckDBTypeId.UUID) {
  const uuidHugeint = columnValue.hugeint; // bigint
  const uuidString = columnValue.toString();
}

// other possible values are: null, boolean, number, bigint, or string
```

Displaying Timezones

Converting a TIMESTAMP_TZ value to a string depends on a timezone offset. By default, this is set to the offset for the local timezone when the Node process is started.

To change it, set the `timezoneOffsetInMinutes` property of `DuckDBTimestampTZValue`:

```
DuckDBTimestampTZValue.timezoneOffsetInMinutes = -8 * 60;
const pst = DuckDBTimestampTZValue.Epoch.toString();
// 1969-12-31 16:00:00-08

DuckDBTimestampTZValue.timezoneOffsetInMinutes = +1 * 60;
```

```
const cet = DuckDBTimestampTZValue.Epoch.toString();
// 1970-01-01 01:00:00+01
```

Note that the timezone offset used for this string conversion is distinct from the `TimeZone` setting of DuckDB.

The following sets this offset to match the `TimeZone` setting of DuckDB:

```
const reader = await connection.runAndReadAll(
  `select (timezone(current_timestamp) / 60)::int`
);
DuckDBTimestampTZValue.timezoneOffsetInMinutes =
  reader.getColumns()[0][0];
```

Append To Table

```
await connection.run(
  `create or replace table target_table(i integer, v varchar)`
);

const appender = await connection.createAppender('target_table');

appender.appendInteger(42);
appender.appendVarchar('duck');
appender.endRow();

appender.appendInteger(123);
appender.appendVarchar('mallard');
appender.endRow();

appender.flushSync();

appender.appendInteger(17);
appender.appendVarchar('goose');
appender.endRow();

appender.closeSync(); // also flushes
```

Append Data Chunk

```
await connection.run(
  `create or replace table target_table(i integer, v varchar)`
);

const appender = await connection.createAppender('target_table');

const chunk = DuckDBDataChunk.create([INTEGER, VARCHAR]);
chunk.setColumns([
  [42, 123, 17],
  ['duck', 'mallard', 'goose'],
]);
// OR:
// chunk.setRows([
//   [42, 'duck'],
//   [123, 'mallard'],
//   [17, 'goose'],
// ]);

appender.appendDataChunk(chunk);
appender.flushSync();
```

See "Specifying Values" above for how to supply values to the appender.

Extract Statements

```
const extractedStatements = await connection.extractStatements(`
  create or replace table numbers as from range(?);
  from numbers where range < ?;
  drop table numbers;
`);
const parameterValues = [10, 7];
const statementCount = extractedStatements.count;
for (let stmtIndex = 0; stmtIndex < statementCount; stmtIndex++) {
  const prepared = await extractedStatements.prepare(stmtIndex);
  let parameterCount = prepared.parameterCount;
  for (let paramIndex = 1; paramIndex <= parameterCount; paramIndex++) {
    prepared.bindInteger(paramIndex, parameterValues.shift());
  }
  const result = await prepared.run();
  // ...
}
```

Control Evaluation of Tasks

```
import { DuckDBPendingResultState } from '@duckdb/node-api';

async function sleep(ms) {
  return new Promise((resolve) => {
    setTimeout(resolve, ms);
  });
}

const prepared = await connection.prepare('from range(10_000_000)');
const pending = prepared.start();
while (pending.runTask() !== DuckDBPendingResultState.RESULT_READY) {
  console.log('not ready');
  await sleep(1);
}
console.log('ready');
const result = await pending.getResult();
// ...
```

Ways to Run SQL

```
// Run to completion but don't yet retrieve any rows.
// Optionally take values to bind to SQL parameters,
// and (optionally) types of those parameters,
// either as an array (for positional parameters),
// or an object keyed by parameter name.
const result = await connection.run(sql);
const result = await connection.run(sql, values);
const result = await connection.run(sql, values, types);

// Run to completion but don't yet retrieve any rows.
// Wrap in a DuckDBDataReader for convenient data retrieval.
const reader = await connection.runAndRead(sql);
const reader = await connection.runAndRead(sql, values);
const reader = await connection.runAndRead(sql, values, types);
```

```
// Run to completion, wrap in a reader, and read all rows.
const reader = await connection.runAndReadAll(sql);
const reader = await connection.runAndReadAll(sql, values);
const reader = await connection.runAndReadAll(sql, values, types);

// Run to completion, wrap in a reader, and read at least
// the given number of rows. (Rows are read in chunks, so more than
// the target may be read.)
const reader = await connection.runAndReadUntil(sql, targetRowCount);
const reader =
  await connection.runAndReadAll(sql, targetRowCount, values);
const reader =
  await connection.runAndReadAll(sql, targetRowCount, values, types);

// Create a streaming result and don't yet retrieve any rows.
const result = await connection.stream(sql);
const result = await connection.stream(sql, values);
const result = await connection.stream(sql, values, types);

// Create a streaming result and don't yet retrieve any rows.
// Wrap in a DuckDBDataReader for convenient data retrieval.
const reader = await connection.streamAndRead(sql);
const reader = await connection.streamAndRead(sql, values);
const reader = await connection.streamAndRead(sql, values, types);

// Create a streaming result, wrap in a reader, and read all rows.
const reader = await connection.streamAndReadAll(sql);
const reader = await connection.streamAndReadAll(sql, values);
const reader = await connection.streamAndReadAll(sql, values, types);

// Create a streaming result, wrap in a reader, and read at least
// the given number of rows.
const reader = await connection.streamAndReadUntil(sql, targetRowCount);
const reader =
  await connection.streamAndReadUntil(sql, targetRowCount, values);
const reader =
  await connection.streamAndReadUntil(sql, targetRowCount, values, types);

// Prepared Statements

// Prepare a possibly-parametered SQL statement to run later.
const prepared = await connection.prepare(sql);

// Bind values to the parameters.
prepared.bind(values);
prepared.bind(values, types);

// Run the prepared statement. These mirror the methods on the connection.
const result = prepared.run();

const reader = prepared.runAndRead();
const reader = prepared.runAndReadAll();
const reader = prepared.runAndReadUntil(targetRowCount);

const result = prepared.stream();

const reader = prepared.streamAndRead();
const reader = prepared.streamAndReadAll();
const reader = prepared.streamAndReadUntil(targetRowCount);
```

```
// Pending Results

// Create a pending result.
const pending = await connection.start(sql);
const pending = await connection.start(sql, values);
const pending = await connection.start(sql, values, types);

// Create a pending, streaming result.
const pending = await connection.startStream(sql);
const pending = await connection.startStream(sql, values);
const pending = await connection.startStream(sql, values, types);

// Create a pending result from a prepared statement.
const pending = await prepared.start();
const pending = await prepared.startStream();

while (pending.runTask() !== DuckDBPendingResultState.RESULT_READY) {
  // optionally sleep or do other work between tasks
}

// Retrieve the result. If not yet READY, will run until it is.
const result = await pending.getResult();

const reader = await pending.read();
const reader = await pending.readAll();
const reader = await pending.readUntil(targetRowCount);
```

Ways to Get Result Data

```
// From a result

// Asynchronously retrieve data for all rows:
const columns = await result.getColumns();
const columnsJson = await result.getColumnsJson();
const columnsObject = await result.getColumnsObject();
const columnsObjectJson = await result.getColumnsObjectJson();
const rows = await result.getRows();
const rowsJson = await result.getRowsJson();
const rowObjects = await result.getRowObjects();
const rowObjectsJson = await result.getRowObjectsJson();

// From a reader

// First, (asynchronously) read some rows:
await reader.readAll();
// or:
await reader.readUntil(targetRowCount);

// Then, (synchronously) get result data for the rows read:
const columns = reader.getColumns();
const columnsJson = reader.getColumnsJson();
const columnsObject = reader.getColumnsObject();
const columnsObjectJson = reader.getColumnsObjectJson();
const rows = reader.getRows();
const rowsJson = reader.getRowsJson();
const rowObjects = reader.getRowObjects();
const rowObjectsJson = reader.getRowObjectsJson();
```

```
// Individual values can also be read directly:
const value = reader.value(columnIndex, rowIndex);

// Using chunks

// If desired, one or more chunks can be fetched from a result:
const chunk = await result.fetchChunk();
const chunks = await result.fetchAllChunks();

// And then data can be retrieved from each chunk:
const columnValues = chunk.getColumnValues(columnIndex);
const columns = chunk.getColumns();
const rowValues = chunk.getRowValues(rowIndex);
const rows = chunk.getRows();

// Or, values can be visited:
chunk.visitColumnValues(columnIndex,
  (value, rowIndex, columnIndex, type) => { /* ... */ }
);
chunk.visitColumns((column, columnIndex, type) => { /* ... */ });
chunk.visitColumnMajor(
  (value, rowIndex, columnIndex, type) => { /* ... */ }
);
chunk.visitRowValues(rowIndex,
  (value, rowIndex, columnIndex, type) => { /* ... */ }
);
chunk.visitRows((row, rowIndex) => { /* ... */ });
chunk.visitRowMajor(
  (value, rowIndex, columnIndex, type) => { /* ... */ }
);

// Or converted:
// The `converter` argument implements `DuckDBValueConverter`,
// which has the single method convertValue(value, type).
const columnValues = chunk.convertColumnValues(columnIndex, converter);
const columns = chunk.convertColumns(converter);
const rowValues = chunk.convertRowValues(rowIndex, converter);
const rows = chunk.convertRows(converter);

// The reader abstracts these low-level chunk manipulations
// and is recommended for most cases.
```

ODBC

ODBC API Overview

> Installation To use the DuckDB ODBC client, visit the ODBC installation page.
>
> The latest stable version of the DuckDB ODBC client is {% if site.current_duckdb_odbc_short_version != "" %}{{ site.current_duckdb_odbc_short_version }}{% else %}{{ site.lts_duckdb_odbc_short_version }}{% endif %}.

The ODBC (Open Database Connectivity) is a C-style API that provides access to different flavors of Database Management Systems (DBMSs). The ODBC API consists of the Driver Manager (DM) and the ODBC drivers.

The Driver Manager is part of the system library, e.g., unixODBC, which manages the communications between the user applications and the ODBC drivers. Typically, applications are linked against the DM, which uses Data Source Name (DSN) to look up the correct ODBC driver.

The ODBC driver is a DBMS implementation of the ODBC API, which handles all the internals of that DBMS.

The DM maps user application calls of ODBC functions to the correct ODBC driver that performs the specified function and returns the proper values.

DuckDB ODBC Driver

DuckDB supports the ODBC version 3.0 according to the Core Interface Conformance.

The ODBC driver is available for all operating systems. Visit the installation page for direct links.

ODBC API on Linux

Driver Manager

A driver manager is required to manage communication between applications and the ODBC driver. We tested and support `unixODBC` that is a complete ODBC driver manager for Linux. Users can install it from the command line:

On Debian-based distributions (Ubuntu, Mint, etc.), run:

```
sudo apt-get install unixodbc odbcinst
```

On Fedora-based distributions (Amazon Linux, RHEL, CentOS, etc.), run:

```
sudo yum install unixODBC
```

Setting Up the Driver

1. Download the ODBC Linux Asset corresponding to your architecture:
    - [x86_64 (AMD64)](https://github.com/duckdb/duckdb-odbc/releases/download/v%7B% if site.current_duckdb_odbc_version != "" %}1.5.4.0{% else %}{{ site.lts_duckdb_odbc_version }}{% endif %}/duckdb_odbc-linux-amd64.zip)
    - [arm64 (AArch64)](https://github.com/duckdb/duckdb-odbc/releases/download/v%7B% if site.current_duckdb_odbc_version != "" %}1.5.4.0{% else %}{{ site.lts_duckdb_odbc_version }}{% endif %}/duckdb_odbc-linux-aarch64.zip)

2. The package contains the following files:

   - `libduckdb_odbc.so`: the DuckDB driver.
   - `unixodbc_setup.sh`: a setup script to aid the configuration on Linux.

   To extract them, run:

   ```
   mkdir duckdb_odbc && unzip duckdb_odbc-linux-amd64.zip -d duckdb_odbc
   ```

3. The `unixodbc_setup.sh` script performs the configuration of the DuckDB ODBC Driver. It is based on the unixODBC package that provides some commands to handle the ODBC setup and test like `odbcinst` and `isql`.

   Run the following commands with either option `-u` or `-s` to configure DuckDB ODBC.

   The `-u` option based on the user home directory to setup the ODBC init files.

   ```
   ./unixodbc_setup.sh -u
   ```

   The `-s` option changes the system level files that will be visible for all users, because of that it requires root privileges.

   ```
   sudo ./unixodbc_setup.sh -s
   ```

   The option `--help` shows the usage of `unixodbc_setup.sh` prints the help.

   ```
   ./unixodbc_setup.sh --help
   ```

   ```
   Usage: ./unixodbc_setup.sh <level> [options]

   Example: ./unixodbc_setup.sh -u -db ~/database_path -D ~/driver_path/libduckdb_odbc.so

   Level:
   -s: System-level, using 'sudo' to configure DuckDB ODBC at the system-level, changing the files:
   /etc/odbc[inst].ini
   -u: User-level, configuring the DuckDB ODBC at the user-level, changing the files:
   ~/.odbc[inst].ini.

   Options:
   -db database_path>: the DuckDB database file path, the default is ':memory:' if not provided.
   -D driver_path: the driver file path (i.e., the path for libduckdb_odbc.so), the default is using
   the base script directory
   ```

4. The ODBC setup on Linux is based on the `.odbc.ini` and `.odbcinst.ini` files.

   These files can be placed to the user home directory `/home/<username>`{:.language-sql .highlight} or in the system `/etc`{:.language-sql .highlight} directory. The Driver Manager prioritizes the user configuration files over the system files.

   For the details of the configuration parameters, see the ODBC configuration page.

ODBC API on Windows

Setup

Using the DuckDB ODBC API on Windows requires the following steps:

1. Microsoft Windows requires an ODBC Driver Manager to manage communication between applications and the ODBC drivers. The Driver Manager on Windows is provided in a DLL file `odbccp32.dll`, and other files and tools. For detailed information check out the Common ODBC Component Files.

2. DuckDB releases the ODBC driver as an asset. For Windows, download it from the [Windows ODBC asset (x86_64/AMD64)](https://github.com/duckdb/duckdb-odbc/releases/download/v%7B% if site.current_duckdb_odbc_version != "" %}1.5.4.0{% else %}{{ site.lts_duckdb_odbc_version }}{% endif %}/duckdb_odbc-windows-amd64.zip).

3. The archive contains the following artifacts:

   - `duckdb_odbc.dll`: the DuckDB driver compiled for Windows.
   - `duckdb_odbc_setup.dll`: a setup DLL used by the Windows ODBC Data Source Administrator tool.
   - `odbc_install.exe`: an installation script to aid the configuration on Windows.

   Decompress the archive to a directory (e.g., `duckdb_odbc`).

4. The `odbc_install.exe` binary performs the configuration of the DuckDB ODBC Driver on Windows. It depends on the `Odbccp32.dll` that provides functions to configure the ODBC registry entries.

   Inside the permanent directory (e.g., `duckdb_odbc`), double-click on the `odbc_install.exe`.

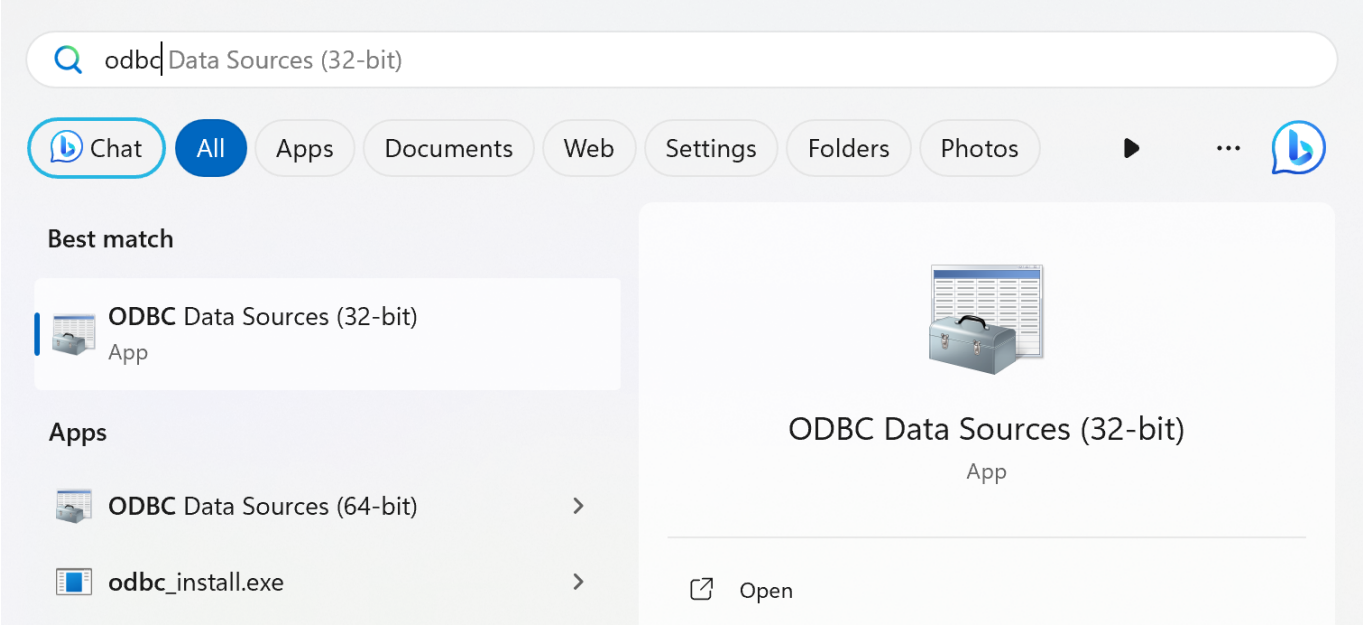
   Windows administrator privileges are required. In case of a non-administrator, a User Account Control prompt will occur.

5. `odbc_install.exe` adds a default DSN configuration into the ODBC registries with a default database `:memory:`.

DSN Windows Setup

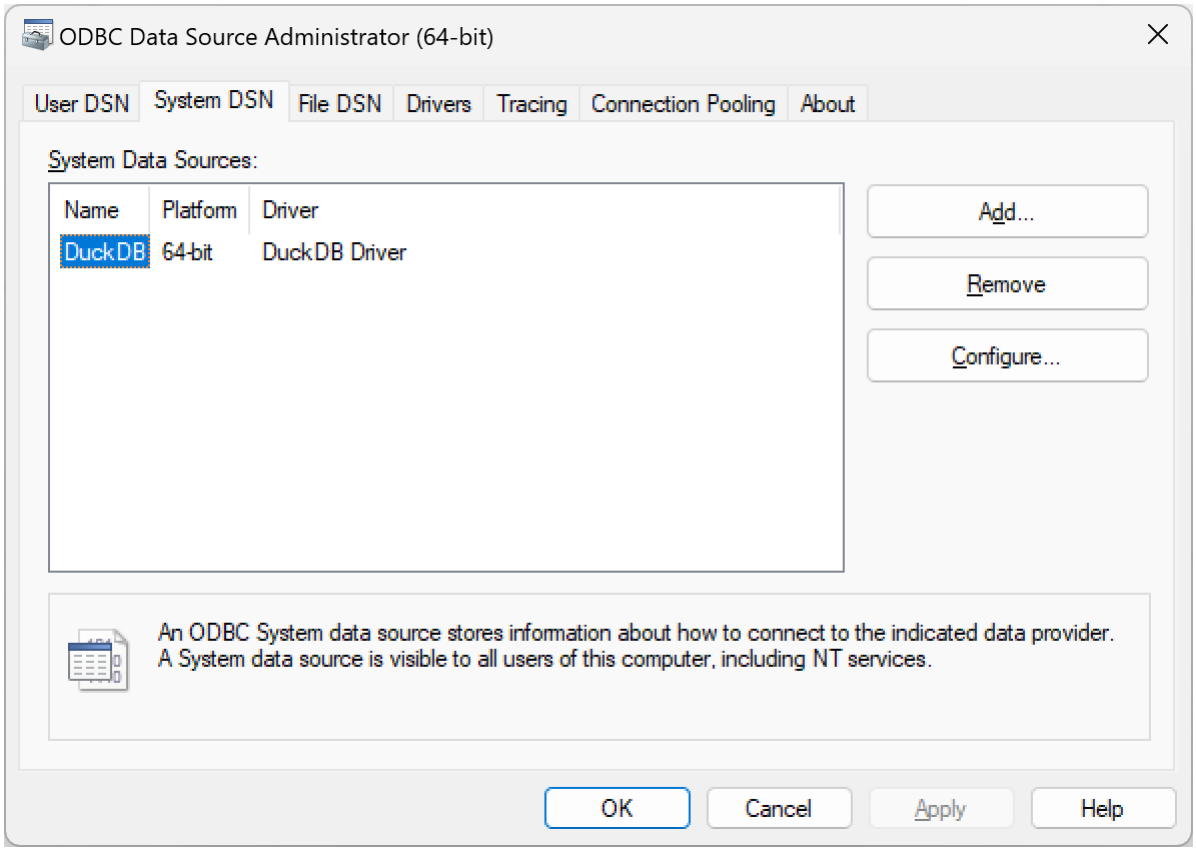
After the installation, it is possible to change the default DSN configuration or add a new one using the Windows ODBC Data Source Administrator tool `odbcad32.exe`.

It also can be launched through the Windows start:



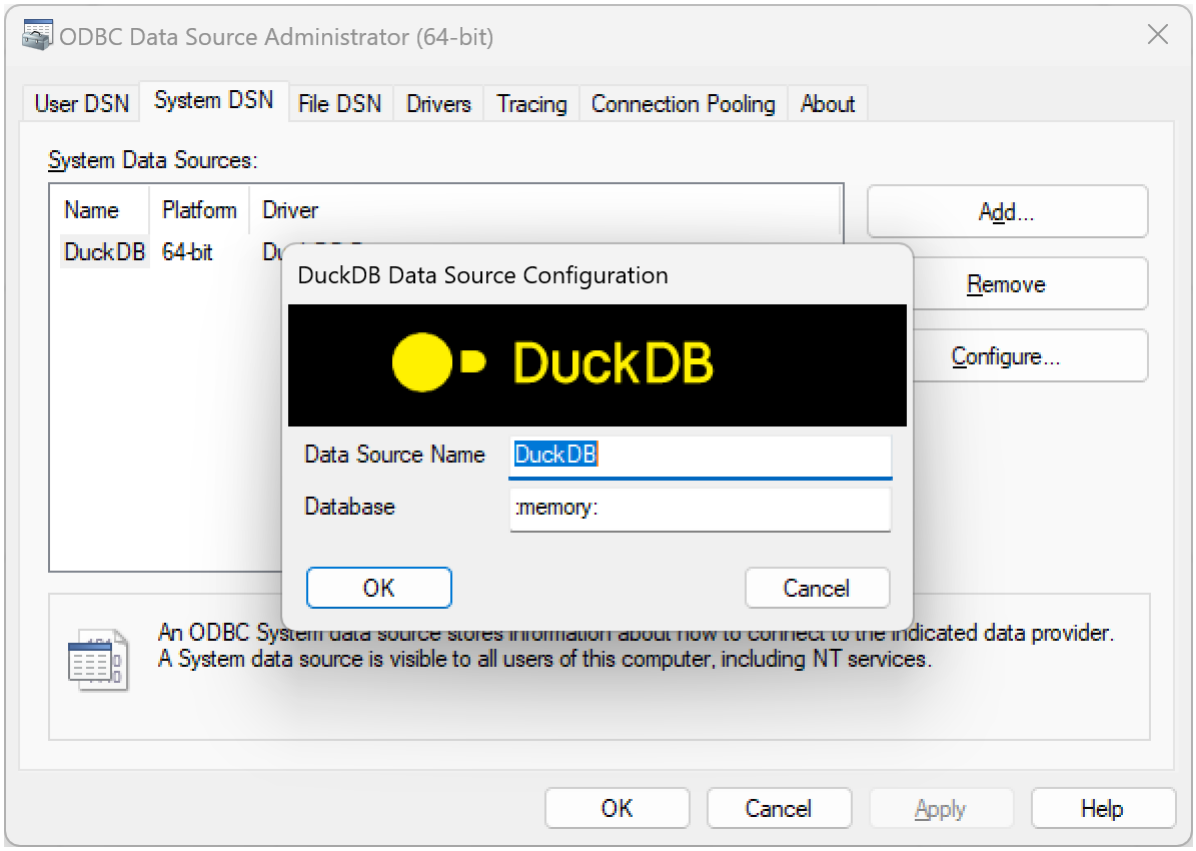
Default DuckDB DSN

The newly installed DSN is visible on the ***System DSN*** in the Windows ODBC Data Source Administrator tool:



Changing DuckDB DSN

When selecting the default DSN (i.e., DuckDB) or adding a new configuration, the following setup window will display:



This window allows you to set the DSN and the database file path associated with that DSN.

More Detailed Windows Setup

There are two ways to configure the ODBC driver, either by altering the registry keys as detailed below, or by connecting with `SQLDriverConnect`. A combination of the two is also possible.

Furthermore, the ODBC driver supports all the configuration options included in DuckDB.

> If a configuration is set in both the connection string passed to `SQLDriverConnect` and in the `odbc.ini` file, the one passed to `SQLDriverConnect` will take precedence.

For the details of the configuration parameters, see the ODBC configuration page.

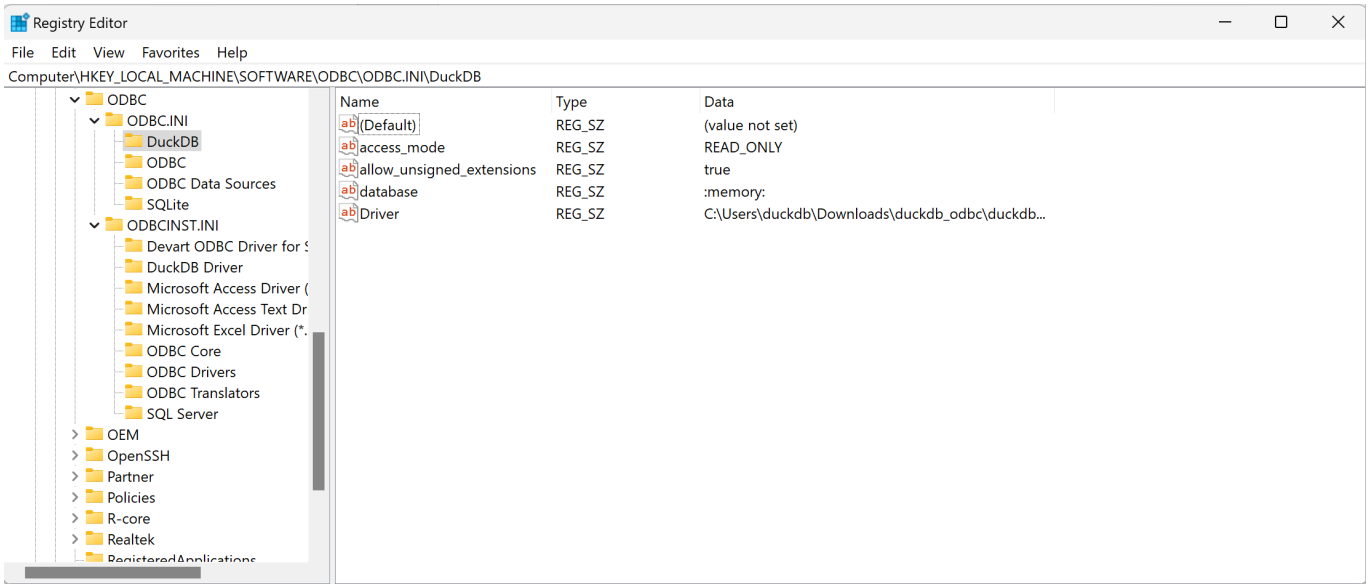
Registry Keys

The ODBC setup on Windows is based on registry keys (see Registry Entries for ODBC Components). The ODBC entries can be placed at the current user registry key (HKCU) or the system registry key (HKLM).

We have tested and used the system entries based on `HKLM->SOFTWARE->ODBC`. The `odbc_install.exe` changes this entry that has two subkeys: `ODBC.INI` and `ODBCINST.INI`.

The `ODBC.INI` is where users usually insert DSN registry entries for the drivers.

For example, the DSN registry for DuckDB would look like this:



The `ODBCINST.INI` contains one entry for each ODBC driver and other keys predefined for Windows ODBC configuration.

Updating the ODBC Driver

When a new version of the ODBC driver is released, installing the new version will overwrite the existing one. However, the installer doesn't always update the version number in the registry. To ensure the correct version is used, check that `HKEY_LOCAL_MACHINE\SOFTWARE\ODBC\ODBCINST.INI\DuckDB Driver` has the most recent version, and `HKEY_LOCAL_MACHINE\SOFTWARE\ODBC\ODBC.INI\DuckDB\Driver` has the correct path to the new driver.

ODBC API on macOS

1. A driver manager is required to manage communication between applications and the ODBC driver. DuckDB supports `unixODBC`, which is a complete ODBC driver manager for macOS and Linux. Users can install it from the command line via Homebrew:

   ```
   brew install unixodbc
   ```

2. DuckDB releases a universal [ODBC driver for macOS](https://github.com/duckdb/duckdb-odbc/releases/download/v%7B% if site.current_duckdb_odbc_version != "" %}1.5.4.0{% else %}{{ site.lts_duckdb_odbc_version }}{% endif %}/duckdb_odbc-osx-universal.zip) (supporting both Intel and Apple Silicon CPUs). To download it, run:

```
wget https://github.com/duckdb/duckdb-odbc/releases/download/v{% if site.current_duckdb_odbc_version != "" %}1.5.4.0{% else %}{{ site.lts_duckdb_odbc_version }}{% endif %}/duckdb_odbc-osx-universal.zip
```

1. The archive contains the `libduckdb_odbc.dylib` artifact. To extract it to a directory, run:

   ```
   mkdir duckdb_odbc && unzip duckdb_odbc-osx-universal.zip -d duckdb_odbc
   ```

2. There are two ways to configure the ODBC driver, either by initializing via the configuration files, or by connecting with `SQLDriverConnect`. A combination of the two is also possible.

   Furthermore, the ODBC driver supports all the configuration options included in DuckDB.

   > If a configuration is set in both the connection string passed to `SQLDriverConnect` and in the `odbc.ini` file, the one passed to `SQLDriverConnect` will take precedence.

   For the details of the configuration parameters, see the ODBC configuration page.

3. After the configuration, to validate the installation, it is possible to use an ODBC client. unixODBC uses a command line tool called `isql`.

   Use the DSN defined in `odbc.ini` as a parameter of `isql`.

```
isql DuckDB

+---------------------------------------+
| Connected!                            |
|                                       |
| sql-statement                         |
| help [tablename]                      |
| echo [string]                         |
| quit                                  |
|                                       |
+---------------------------------------+

SQL> SELECT 42;

+------------+
| 42         |
+------------+
| 42         |
+------------+

SQLRowCount returns -1
1 rows fetched
```

ODBC Configuration

This page documents the files using the ODBC configuration, `odbc.ini` and `odbcinst.ini`. These are either placed in the home directory as dotfiles (`.odbc.ini` and `.odbcinst.ini`, respectively) or in a system directory. For platform-specific details, see the pages for Linux, macOS, and Windows.

`odbc.ini` and `.odbc.ini`

The `odbc.ini` file contains the DSNs for the drivers, which can have specific knobs. An example of `odbc.ini` with DuckDB:

```
[DuckDB]
Driver = DuckDB Driver
Database = :memory:
access_mode = read_only
```

The lines correspond to the following parameters:

- `[DuckDB]`: between the brackets is a DSN for the DuckDB.
- `Driver`: Describes the driver's name, as well as where to find the configurations in the `odbcinst.ini`.
- `Database`: Describes the database name used by DuckDB, can also be a file path to a `.db` in the system.
- `access_mode`: The mode in which to connect to the database.

`odbcinst.ini` and `.odbcinst.ini`

The `odbcinst.ini` file contains general configurations for the ODBC installed drivers in the system. A driver section starts with the driver name between brackets, and then it follows specific configuration knobs belonging to that driver.

Example of `odbcinst.ini` with the DuckDB:

```
[ODBC]
Trace = yes
TraceFile = /tmp/odbctrace

[DuckDB Driver]
Driver = /path/to/libduckdb_odbc.dylib
```

The lines correspond to the following parameters:

- `[ODBC]`: The DM configuration section.
- `Trace`: Enables the ODBC trace file using the option `yes`.
- `TraceFile`: The absolute system file path for the ODBC trace file.
- `[DuckDB Driver]`: The section of the DuckDB installed driver.
- `Driver`: The absolute system file path of the DuckDB driver. Change to match your configuration.

Python

Python API

> Installation To use the DuckDB Python client, visit the Python installation page.
>
> The latest stable version of the DuckDB Python client is 1.5.4.

Installation

The DuckDB Python API can be installed using pip: `pip install duckdb`. Please see the installation page: `conda install python-duckdb -c conda-forge`.

Python version: DuckDB requires Python 3.9 or newer.

Basic API Usage

The most straight-forward manner of running SQL queries using DuckDB is using the `duckdb.sql` command.

```
import duckdb

duckdb.sql("SELECT 42").show()
```

This will run queries using an **in-memory database** that is stored globally inside the Python module. The result of the query is returned as a **Relation**. A relation is a symbolic representation of the query. The query is not executed until the result is fetched or requested to be printed to the screen.

Relations can be referenced in subsequent queries by storing them inside variables, and using them as tables. This way queries can be constructed incrementally.

```
import duckdb

r1 = duckdb.sql("SELECT 42 AS i")
duckdb.sql("SELECT i * 2 AS k FROM r1").show()
```

Data Input

DuckDB can ingest data from a wide variety of formats – both on-disk and in-memory. See the data ingestion page for more information.

```
import duckdb

duckdb.read_csv("example.csv")                # read a CSV file into a Relation
duckdb.read_parquet("example.parquet")        # read a Parquet file into a Relation
duckdb.read_json("example.json")              # read a JSON file into a Relation

duckdb.sql("SELECT * FROM 'example.csv'")     # directly query a CSV file
duckdb.sql("SELECT * FROM 'example.parquet'") # directly query a Parquet file
duckdb.sql("SELECT * FROM 'example.json'")    # directly query a JSON file
```

DataFrames

DuckDB can directly query Pandas DataFrames, Polars DataFrames and Arrow tables. Note that these are read-only, i.e., editing these tables via INSERT or UPDATE statements is not possible.

Pandas To directly query a Pandas DataFrame, run:

```
import duckdb
import pandas as pd

pandas_df = pd.DataFrame({"a": [42]})
duckdb.sql("SELECT * FROM pandas_df")
```

```
┌─────────┐
│    a    │
│  int64  │
├─────────┤
│      42 │
└─────────┘
```

Polars To directly query a Polars DataFrame, run:

```
import duckdb
import polars as pl

polars_df = pl.DataFrame({"a": [42]})
duckdb.sql("SELECT * FROM polars_df")
```

```
┌─────────┐
│    a    │
│  int64  │
├─────────┤
│      42 │
└─────────┘
```

PyArrow To directly query a PyArrow table, run:

```
import duckdb
import pyarrow as pa

arrow_table = pa.Table.from_pydict({"a": [42]})
duckdb.sql("SELECT * FROM arrow_table")
```

```
┌─────────┐
│    a    │
│  int64  │
├─────────┤
│      42 │
└─────────┘
```

Result Conversion

DuckDB supports converting query results efficiently to a variety of formats. See the result conversion page for more information.

```
import duckdb

duckdb.sql("SELECT 42").fetchall()   # Python objects
duckdb.sql("SELECT 42").df()         # Pandas DataFrame
```

```
duckdb.sql("SELECT 42").pl()          # Polars DataFrame
duckdb.sql("SELECT 42").arrow()       # Arrow Table
duckdb.sql("SELECT 42").fetchnumpy() # NumPy Arrays
```

Writing Data to Disk

DuckDB supports writing Relation objects directly to disk in a variety of formats. The COPY statement can be used to write data to disk using SQL as an alternative.

```
import duckdb

duckdb.sql("SELECT 42").write_parquet("out.parquet") # Write to a Parquet file
duckdb.sql("SELECT 42").write_csv("out.csv")         # Write to a CSV file
duckdb.sql("COPY (SELECT 42) TO 'out.parquet'")      # Copy to a Parquet file
```

Connection Options

Applications can open a new DuckDB connection via the `duckdb.connect()` method.

Using an In-Memory Database

When using DuckDB through `duckdb.sql()`, it operates on an **in-memory** database, i.e., no tables are persisted on disk. Invoking the `duckdb.connect()` method without arguments returns a connection, which also uses an in-memory database:

```
import duckdb

con = duckdb.connect()
con.sql("SELECT 42 AS x").show()
```

Persistent Storage

The `duckdb.connect(dbname)` creates a connection to a **persistent** database. Any data written to that connection will be persisted, and can be reloaded by reconnecting to the same file, both from Python and from other DuckDB clients.

```
import duckdb

# create a connection to a file called 'file.db'
con = duckdb.connect("file.db")
# create a table and load data into it
con.sql("CREATE TABLE test (i INTEGER)")
con.sql("INSERT INTO test VALUES (42)")
# query the table
con.table("test").show()
# explicitly close the connection
con.close()
# Note: connections also closed implicitly when they go out of scope
```

You can also use a context manager to ensure that the connection is closed:

```
import duckdb

with duckdb.connect("file.db") as con:
    con.sql("CREATE TABLE test (i INTEGER)")
    con.sql("INSERT INTO test VALUES (42)")
    con.table("test").show()
    # the context manager closes the connection automatically
```

Configuration

The `duckdb.connect()` accepts a `config` dictionary, where configuration options can be specified. For example:

```
import duckdb

con = duckdb.connect(config = {'threads': 1})
```

To specify the storage version, pass the `storage_compatibility_version` option:

```
import duckdb

con = duckdb.connect(config = {'storage_compatibility_version': 'latest'})
```

Connection Object and Module

The connection object and the `duckdb` module can be used interchangeably – they support the same methods. The only difference is that when using the `duckdb` module a global in-memory database is used.

> If you are developing a package designed for others to use, and use DuckDB in the package, it is recommended that you create connection objects instead of using the methods on the `duckdb` module. That is because the `duckdb` module uses a shared global database – which can cause hard to debug issues if used from within multiple different packages.

Using Connections in Parallel Python Programs

Thread Safety of `duckdb.sql()` and the Global Connection `duckdb.sql()` and `duckdb.connect(':default:')` use a shared global in-memory connection. This connection is not thread-safe, and running queries on it from multiple threads can cause issues. To run DuckDB in parallel, each thread must have its own connection:

```
def good_use():
    con = duckdb.connect()
    # uses new connection
    con.sql("SELECT 1").fetchall()
```

Conversely, the following could cause concurrency issues because they rely on a global connection:

```
def bad_use():
    con = duckdb.connect(':default:')
    # uses global connection
    return con.sql("SELECT 1").fetchall()
```

Or:

```
def also_bad():
    return duckdb.sql("SELECT 1").fetchall()
    # uses global connection
```

Avoid using `duckdb.sql()` or sharing a single connection across threads.

About `cursor()` A `DuckDBPyConnection.cursor()` method creates another handle on the same connection. It does not open a new connection. Therefore, all cursors created from one connection cannot run queries at the same time.

Community Extensions

To load community extensions, use the `repository="community"` argument with the `install_extension` method.

For example, install and load the `h3` community extension as follows:

```
import duckdb

con = duckdb.connect()
con.install_extension("h3", repository="community")
con.load_extension("h3")
```

Unsigned Extensions

To load unsigned extensions, use:

```
con = duckdb.connect(config={"allow_unsigned_extensions": "true"})
```

> **Warning.** Only load unsigned extensions from sources you trust. Avoid loading unsigned extensions over HTTP. Consult the Securing DuckDB page for guidelines on how set up DuckDB in a secure manner.

Data Ingestion

This page contains examples for data ingestion to Python using DuckDB. First, import the DuckDB package:

```
import duckdb
```

Then, proceed with any of the following sections.

CSV Files

CSV files can be read using the `read_csv` function, called either from within Python or directly from within SQL. By default, the `read_csv` function attempts to auto-detect the CSV settings by sampling from the provided file.

Read from a file using fully auto-detected settings:

```
duckdb.read_csv("example.csv")
```

Read multiple CSV files from a folder:

```
duckdb.read_csv("folder/*.csv")
```

Specify options on how the CSV is formatted internally:

```
duckdb.read_csv("example.csv", header = False, sep = ",")
```

Override types of the first two columns:

```
duckdb.read_csv("example.csv", dtype = ["int", "varchar"])
```

Directly read a CSV file from within SQL:

```
duckdb.sql("SELECT * FROM 'example.csv'")
```

Call `read_csv` from within SQL:

```
duckdb.sql("SELECT * FROM read_csv('example.csv')")
```

See the CSV Import page for more information.

Parquet Files

Parquet files can be read using the `read_parquet` function, called either from within Python or directly from within SQL.

Read from a single Parquet file:

```
duckdb.read_parquet("example.parquet")
```

Read multiple Parquet files from a folder:

```
duckdb.read_parquet("folder/*.parquet")
```

Read a Parquet file over https:

```
duckdb.read_parquet("https://some.url/some_file.parquet")
```

Read a list of Parquet files:

```
duckdb.read_parquet(["file1.parquet", "file2.parquet", "file3.parquet"])
```

Directly read a Parquet file from within SQL:

```
duckdb.sql("SELECT * FROM 'example.parquet'")
```

Call `read_parquet` from within SQL:

```
duckdb.sql("SELECT * FROM read_parquet('example.parquet')")
```

See the Parquet Loading page for more information.

JSON Files

JSON files can be read using the `read_json` function, called either from within Python or directly from within SQL. By default, the `read_json` function will automatically detect if a file contains newline-delimited JSON or regular JSON, and will detect the schema of the objects stored within the JSON file.

Read from a single JSON file:

```
duckdb.read_json("example.json")
```

Read multiple JSON files from a folder:

```
duckdb.read_json("folder/*.json")
```

Directly read a JSON file from within SQL:

```
duckdb.sql("SELECT * FROM 'example.json'")
```

Call `read_json` from within SQL:

```
duckdb.sql("SELECT * FROM read_json('example.json')")
```

Directly Accessing DataFrames and Arrow Objects

DuckDB is automatically able to query certain Python variables by referring to their variable name (as if it was a table). These types include the following: Pandas DataFrame, Polars DataFrame, Polars LazyFrame, NumPy arrays, relations and Arrow objects.

Only variables that are visible to Python code at the location of the `sql()` or `execute()` call can be used in this manner. Accessing these variables is made possible by replacement scans. To disable replacement scans entirely, use:

```
SET python_enable_replacements = false;
```

DuckDB supports querying multiple types of Apache Arrow objects including tables, datasets, RecordBatchReaders and scanners. See the Python guides for more examples.

```
import duckdb
import pandas as pd

test_df = pd.DataFrame.from_dict({"i": [1, 2, 3, 4], "j": ["one", "two", "three", "four"]})
print(duckdb.sql("SELECT * FROM test_df").fetchall())
```

```
[(1, 'one'), (2, 'two'), (3, 'three'), (4, 'four')]
```

DuckDB also supports "registering" a DataFrame or Arrow object as a virtual table, comparable to a SQL `VIEW`. This is useful when querying a DataFrame/Arrow object that is stored in another way (as a class variable, or a value in a dictionary). Below is a Pandas example:

If your Pandas DataFrame is stored in another location, here is an example of manually registering it:

```
import duckdb
import pandas as pd

my_dictionary = {}
my_dictionary["test_df"] = pd.DataFrame.from_dict({"i": [1, 2, 3, 4], "j": ["one", "two", "three",
"four"]})
duckdb.register("test_df_view", my_dictionary["test_df"])
print(duckdb.sql("SELECT * FROM test_df_view").fetchall())
```

```
[(1, 'one'), (2, 'two'), (3, 'three'), (4, 'four')]
```

You can also create a persistent table in DuckDB from the contents of the DataFrame (or the view):

```
# create a new table from the contents of a DataFrame
con.execute("CREATE TABLE test_df_table AS SELECT * FROM test_df")
# insert into an existing table from the contents of a DataFrame
con.execute("INSERT INTO test_df_table SELECT * FROM test_df")
```

The precedence of objects with the same name is as follows:

- Objects explicitly registered via `register()`
- Native DuckDB tables and views
- Replacement scans

Pandas DataFrames – `object` Columns

`pandas.DataFrame` columns of an `object` dtype require some special care, since this stores values of arbitrary type. To convert these columns to DuckDB, we first go through an analyze phase before converting the values. In this analyze phase a sample of all the rows of the column are analyzed to determine the target type. This sample size is by default set to 1000. If the type picked during the analyze step is incorrect, this will result in `Invalid Input Error: Failed to cast value`, in which case you will need to increase the sample size. The sample size can be changed by setting the `pandas_analyze_sample` config option.

```
# example setting the sample size to 100k
duckdb.execute("SET GLOBAL pandas_analyze_sample = 100_000")
```

Conversion between DuckDB and Python

This page documents the rules for converting Python objects to DuckDB and DuckDB results to Python.

Object Conversion: Python Object to DuckDB

This is a mapping of Python object types to DuckDB Logical Types:

- `None` → `NULL`
- `bool` → `BOOLEAN`

- `datetime.timedelta` → `INTERVAL`
- `str` → `VARCHAR`
- `bytearray` → `BLOB`
- `memoryview` → `BLOB`
- `decimal.Decimal` → `DECIMAL` / `DOUBLE`
- `uuid.UUID` → `UUID`

The rest of the conversion rules are as follows.

`int`

Since integers can be of arbitrary size in Python, there is not a one-to-one conversion possible for ints. Instead we perform these casts in order until one succeeds:

- `BIGINT`
- `INTEGER`
- `UBIGINT`
- `UINTEGER`
- `DOUBLE`

When using the DuckDB Value class, it's possible to set a target type, which will influence the conversion.

`float`

These casts are tried in order until one succeeds:

- `DOUBLE`
- `FLOAT`

`datetime.datetime`

For `datetime` we will check `pandas.isnull` if it's available and return `NULL` if it returns `true`. We check against `datetime.datetime.min` and `datetime.datetime.max` to convert to `-inf` and `+inf` respectively.

If the `datetime` has tzinfo, we will use `TIMESTAMPTZ`, otherwise it becomes `TIMESTAMP`.

`datetime.time`

If the `time` has tzinfo, we will use `TIMETZ`, otherwise it becomes `TIME`.

`datetime.date`

`date` converts to the `DATE` type. We check against `datetime.date.min` and `datetime.date.max` to convert to `-inf` and `+inf` respectively.

`bytes`

`bytes` converts to `BLOB` by default, when it's used to construct a Value object of type `BITSTRING`, it maps to `BITSTRING` instead.

list

`list` becomes a `LIST` type of the "most permissive" type of its children, for example:

```
my_list_value = [
    12345,
    "test"
]
```

Will become `VARCHAR[]` because 12345 can convert to `VARCHAR` but `test` can not convert to `INTEGER`.

```
[12345, test]
```

dict

The `dict` object can convert to either `STRUCT(...)` or `MAP(..., ...)` depending on its structure. If the dict has a structure similar to:

```
import duckdb

my_map_dict = {
    "key": [
        1, 2, 3
    ],
    "value": [
        "one", "two", "three"
    ]
}

duckdb.values(my_map_dict)
```

Then we'll convert it to a `MAP` of key-value pairs of the two lists zipped together. The example above becomes a `MAP(INTEGER, VARCHAR)`:

```
┌──────────────────────────┐
│ {1=one, 2=two, 3=three}  │
│  map(integer, varchar)   │
├──────────────────────────┤
│ {1=one, 2=two, 3=three}  │
└──────────────────────────┘
```

If the dict is returned by a function, the function will return a `MAP`, therefore the function `return_type` has to be specified. Providing a return type which cannot convert to `MAP` will raise an error:

```
import duckdb
duckdb_conn = duckdb.connect()

def get_map() -> dict[str,list[str]|list[int]]:
    return {
        "key": [
            1, 2, 3
        ],
        "value": [
            "one", "two", "three"
        ]
    }

duckdb_conn.create_function("get_map", get_map, return_type=dict[int, str])

duckdb_conn.sql("select get_map()").show()
```

```
duckdb_conn.create_function("get_map_error", get_map)

duckdb_conn.sql("select get_map_error()").show()
```

```
┌──────────────────────────┐
│         get_map()        │
│ map(bigint, varchar)     │
├──────────────────────────┤
│ {1=one, 2=two, 3=three}  │
└──────────────────────────┘
```

```
ConversionException: Conversion Error: Type VARCHAR can't be cast as UNION(u1 VARCHAR[], u2 BIGINT[]).
VARCHAR can't be implicitly cast to any of the union member types: VARCHAR[], BIGINT[]
```

> The names of the fields matter and the two lists need to have the same size.

Otherwise we'll try to convert it to a STRUCT.

```
import duckdb

my_struct_dict = {
    1: "one",
    "2": 2,
    "three": [1, 2, 3],
    False: True
}

duckdb.values(my_struct_dict)
```

Becomes:

```
┌──────────────────────────────────────────────────────────────────────┐
│     {'1': 'one', '2': 2, 'three': [1, 2, 3], 'False': true}         │
│ struct("1" varchar, "2" integer, three integer[], "false" boolean)   │
├──────────────────────────────────────────────────────────────────────┤
│ {'1': one, '2': 2, 'three': [1, 2, 3], 'False': true}                │
└──────────────────────────────────────────────────────────────────────┘
```

If the dict is returned by a function, the function will return a MAP, due to automatic conversion. To return a STRUCT, the `return_type` has to be provided:

```
import duckdb
from duckdb.sqltypes import BOOLEAN, INTEGER, VARCHAR
from duckdb import list_type, struct_type

duckdb_conn = duckdb.connect()

my_struct_dict = {
    1: "one",
    "2": 2,
    "three": [1, 2, 3],
    False: True
}

def get_struct() -> dict[str|int|bool,str|int|list[int]|bool]:
    return my_struct_dict

duckdb_conn.create_function("get_struct_as_map", get_struct)

duckdb_conn.sql("select get_struct_as_map()").show()
```

```
duckdb_conn.create_function("get_struct", get_struct, return_type=struct_type({
    1: VARCHAR,
    "2": INTEGER,
    "three": list_type(INTEGER),
    False: BOOLEAN
}))

duckdb_conn.sql("select get_struct()").show()
```

```
┌──────────────────────────────────────────────────────────────────────────────────────────────────────────────────────┐
│                                                  get_struct_as_map()                                                 │
│ map(union(u1 varchar, u2 bigint, u3 boolean), union(u1 varchar, u2 bigint, u3 bigint[], u4 boolean))                 │
├──────────────────────────────────────────────────────────────────────────────────────────────────────────────────────┤
│ {1=one, 2=2, three=[1, 2, 3], false=true}                                                                            │
└──────────────────────────────────────────────────────────────────────────────────────────────────────────────────────┘
```

```
┌──────────────────────────────────────────────────────────────────┐
│                           get_struct()                           │
│ struct("1" varchar, "2" integer, three integer[], "false" boolean) │
├──────────────────────────────────────────────────────────────────┤
│ {'1': one, '2': 2, 'three': [1, 2, 3], 'False': true}            │
└──────────────────────────────────────────────────────────────────┘
```

> Every key of the dictionary is converted to string.

`tuple`

`tuple` converts to `LIST` by default, when it's used to construct a Value object of type STRUCT it will convert to STRUCT instead.

`numpy.ndarray` and `numpy.datetime64`

`ndarray` and `datetime64` are converted by calling `tolist()` and converting the result of that.

Result Conversion: DuckDB Results to Python

DuckDB's Python client provides multiple additional methods that can be used to efficiently retrieve data.

NumPy

- `fetchnumpy()` fetches the data as a dictionary of NumPy arrays

Pandas

- `df()` fetches the data as a Pandas DataFrame
- `fetchdf()` is an alias of `df()`
- `fetch_df()` is an alias of `df()`
- `fetch_df_chunk(vector_multiple)` fetches a portion of the results into a DataFrame. The number of rows returned in each chunk is the vector size (2048 by default) * vector_multiple (1 by default).

Apache Arrow

- `to_arrow_table()` fetches the data as an Arrow table
- `to_arrow_reader(chunk_size)` returns an Arrow record batch reader with `chunk_size` rows per batch
- `arrow()` returns an Arrow record batch reader. We recommend using `to_arrow_reader()` instead.

> **Deprecated.** `fetch_arrow_table()` and `fetch_record_batch()` are deprecated. Use `to_arrow_table()` and `to_arrow_reader()` instead.

Polars

- `pl()` fetches the data as a Polars DataFrame

Examples

Below are some examples using this functionality. See the Python guides for more examples.

Fetch as Pandas DataFrame:

```
df = con.execute("SELECT * FROM items").fetchdf()
print(df)
```

```
       item   value  count
0     jeans    20.0      1
1    hammer    42.2      2
2    laptop  2000.0      1
3  chainsaw   500.0     10
4    iphone   300.0      2
```

Fetch as dictionary of NumPy arrays:

```
arr = con.execute("SELECT * FROM items").fetchnumpy()
print(arr)
```

```
{'item': masked_array(data=['jeans', 'hammer', 'laptop', 'chainsaw', 'iphone'],
             mask=[False, False, False, False, False],
       fill_value='?',
            dtype=object), 'value': masked_array(data=[20.0, 42.2, 2000.0, 500.0, 300.0],
             mask=[False, False, False, False, False],
       fill_value=1e+20), 'count': masked_array(data=[1, 2, 1, 10, 2],
             mask=[False, False, False, False, False],
       fill_value=999999,
            dtype=int32)}
```

Fetch as an Arrow table. Converting to Pandas afterwards just for pretty printing:

```
tbl = con.execute("SELECT * FROM items").to_arrow_table()
print(tbl.to_pandas())
```

```
       item    value  count
0     jeans    20.00      1
1    hammer    42.20      2
2    laptop  2000.00      1
3  chainsaw   500.00     10
4    iphone   300.00      2
```

Python DB API

The standard DuckDB Python API provides a SQL interface compliant with the DB-API 2.0 specification described by PEP 249 similar to the SQLite Python API.

Connection

To use the module, you must first create a `DuckDBPyConnection` object that represents a connection to a database. This is done through the `duckdb.connect` method.

The 'config' keyword argument can be used to provide a `dict` that contains key->value pairs referencing settings understood by DuckDB.

In-Memory Connection

The special value `:memory:` can be used to create an **in-memory database**. Note that for an in-memory database no data is persisted to disk (i.e., all data is lost when you exit the Python process).

Named In-memory Connections The special value `:memory:` can also be postfixed with a name, for example: `:memory:conn3`. When a name is provided, subsequent `duckdb.connect` calls will create a new connection to the same database, sharing the catalogs (views, tables, macros etc.).

Using `:memory:` without a name will always create a new and separate database instance.

Default Connection

By default we create an (unnamed) **in-memory-database** that lives inside the `duckdb` module. Every method of `DuckDBPyConnection` is also available on the `duckdb` module, this connection is what's used by these methods.

The special value `:default:` can be used to get this default connection.

File-Based Connection

If the `database` is a file path, a connection to a persistent database is established. If the file does not exist the file will be created (the extension of the file is irrelevant and can be `.db`, `.duckdb` or anything else).

`read_only` Connections If you would like to connect in read-only mode, you can set the `read_only` flag to `True`. If the file does not exist, it is **not** created when connecting in read-only mode. Read-only mode is required if multiple Python processes want to access the same database file at the same time.

```
import duckdb

duckdb.execute("CREATE TABLE tbl AS SELECT 42 a")
con = duckdb.connect(":default:")
con.sql("SELECT * FROM tbl")
# or
duckdb.default_connection().sql("SELECT * FROM tbl")
```

```
┌─────────┐
│    a    │
│  int32  │
├─────────┤
│      42 │
└─────────┘
```

```
import duckdb

# to start an in-memory database
con = duckdb.connect(database = ":memory:")
# to use a database file (not shared between processes)
con = duckdb.connect(database = "my-db.duckdb", read_only = False)
# to use a database file (shared between processes)
```

```
con = duckdb.connect(database = "my-db.duckdb", read_only = True)
# to explicitly get the default connection
con = duckdb.connect(database = ":default:")
```

You can obtain another handle on an existing connection with the `cursor()` method. Note that this creates another handle on the *same* connection rather than opening a new connection, so cursors created from one connection cannot run queries at the same time. A single connection is thread-safe but is locked for the duration of each query, effectively serializing database access. See About `cursor()` for details.

Connections are closed implicitly when they go out of scope or if they are explicitly closed using `close()`. Once the last connection to a database instance is closed, the database instance is closed as well.

Querying

SQL queries can be sent to DuckDB using the `execute()` method of connections. Once a query has been executed, results can be retrieved using the `fetchone` and `fetchall` methods on the connection. `fetchall` will retrieve all results and complete the transaction. `fetchone` will retrieve a single row of results each time that it is invoked until no more results are available. The transaction will only close once `fetchone` is called and there are no more results remaining (the return value will be None). As an example, in the case of a query only returning a single row, `fetchone` should be called once to retrieve the results and a second time to close the transaction. Below are some short examples:

```
# create a table
con.execute("CREATE TABLE items (item VARCHAR, value DECIMAL(10, 2), count INTEGER)")
# insert two items into the table
con.execute("INSERT INTO items VALUES ('jeans', 20.0, 1), ('hammer', 42.2, 2)")

# retrieve the items again
con.execute("SELECT * FROM items")
print(con.fetchall())
# [('jeans', Decimal('20.00'), 1), ('hammer', Decimal('42.20'), 2)]

# retrieve the items one at a time
con.execute("SELECT * FROM items")
print(con.fetchone())
# ('jeans', Decimal('20.00'), 1)
print(con.fetchone())
# ('hammer', Decimal('42.20'), 2)
print(con.fetchone()) # This closes the transaction. Any subsequent calls to .fetchone will return None
# None
```

The `description` property of the connection object contains the column names as per the standard.

Prepared Statements

DuckDB also supports prepared statements in the API with the `execute` and `executemany` methods. The values may be passed as an additional parameter after a query that contains `?` or `$1` (dollar symbol and a number) placeholders. Using the `?` notation adds the values in the same sequence as passed within the Python parameter. Using the `$` notation allows for values to be reused within the SQL statement based on the number and index of the value found within the Python parameter. Values are converted according to the conversion rules.

Here are some examples. First, insert a row using a prepared statement:

```
con.execute("INSERT INTO items VALUES (?, ?, ?)", ["laptop", 2000, 1])
```

Second, insert several rows using a prepared statement:

```
con.executemany("INSERT INTO items VALUES (?, ?, ?)", [["chainsaw", 500, 10], ["iphone", 300, 2]] )
```

Query the database using a prepared statement:

```
con.execute("SELECT item FROM items WHERE value > ?", [400])
print(con.fetchall())
```

```
[('laptop',), ('chainsaw',)]
```

Query using the $ notation for a prepared statement and reused values:

```
con.execute("SELECT $1, $1, $2", ["duck", "goose"])
print(con.fetchall())
```

```
[('duck', 'duck', 'goose')]
```

> **Warning.** Do *not* use `executemany` to insert large amounts of data into DuckDB. See the data ingestion page for better options.

Named Parameters

Besides the standard unnamed parameters, like `$1`, `$2` etc., it's also possible to supply named parameters, like `$my_parameter`. When using named parameters, you have to provide a dictionary mapping of `str` to value in the `parameters` argument. An example use is the following:

```
import duckdb

res = duckdb.execute("""
    SELECT
        $my_param,
        $other_param,
        $also_param
    """,
    {
        "my_param": 5,
        "other_param": "DuckDB",
        "also_param": [42]
    }
).fetchall()
print(res)
```

```
[(5, 'DuckDB', [42])]
```

Relational API

The Relational API is an alternative API that can be used to incrementally construct queries. The API is centered around `DuckDBPyRelation` nodes. The relations can be seen as symbolic representations of SQL queries.

Lazy Evaluation

The relations do not hold any data – and nothing is executed – until a method that triggers execution is called.

For example, we create a relation, which loads 1 billion rows:

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("from range(1_000_000_000)")
```

At the moment of execution, `rel` does not hold any data and no data is retrieved from the database.

By calling `rel.show()` or simply printing `rel` on the terminal, the first 10K rows are fetched. If there are more than 10K rows, the output window will show >9999 rows (as the amount of rows in the relation is unknown).

By calling an output method, the data is retrieved and stored in the specified format:

```
rel.to_table("example_rel")

# 100% ▕████████████████████████████████████████████████████████▏
```

Relation Creation

This section contains the details on how a relation is created. The methods are lazy evaluated.

Name	Description
`from_arrow`	Create a relation object from an Arrow object
`from_csv_auto`	Create a relation object from the CSV file in 'name'
`from_df`	Create a relation object from the DataFrame in df
`from_parquet`	Create a relation object from the Parquet files
`from_query`	Run a SQL query. If it is a SELECT statement, create a relation object from the given SQL query, otherwise run the query as-is.
`query`	Run a SQL query. If it is a SELECT statement, create a relation object from the given SQL query, otherwise run the query as-is.
`read_csv`	Create a relation object from the CSV file in 'name'
`read_json`	Create a relation object from the JSON file in 'name'
`read_parquet`	Create a relation object from the Parquet files
`sql`	Run a SQL query. If it is a SELECT statement, create a relation object from the given SQL query, otherwise run the query as-is.
`table`	Create a relation object for the named table
`table_function`	Create a relation object from the named table function with given parameters
`values`	Create a relation object from the passed values
`view`	Create a relation object for the named view

`from_arrow`

Signature

```
from_arrow(self: _duckdb.DuckDBPyConnection, arrow_object: object) -> _duckdb.DuckDBPyRelation
```

Description Create a relation object from an Arrow object

Parameters

- **arrow_object** : pyarrow.Table, pyarrow.RecordBatch

  Arrow object to create a relation from

Example

```
import duckdb
import pyarrow as pa

ids = pa.array([1], type=pa.int8())
texts = pa.array(['a'], type=pa.string())
example_table = pa.table([ids, texts], names=["id", "text"])

duckdb_conn = duckdb.connect()

rel = duckdb_conn.from_arrow(example_table)

rel.show()
```

Result

id int8	text varchar
1	a

`from_csv_auto`

Signature

```
from_csv_auto(self: _duckdb.DuckDBPyConnection, path_or_buffer: object, **kwargs) -> _
duckdb.DuckDBPyRelation
```

Description Create a relation object from the CSV file in 'name'

Aliases: `read_csv`

Parameters

- **path_or_buffer** : Union[str, StringIO, TextIOBase]

  Path to the CSV file or buffer to read from.

- **header** : Optional[bool], Optional[int]

  Row number(s) to use as the column names, or None if no header.

- **compression** : Optional[str]

  Compression type (e.g., 'gzip', 'bz2').

- **sep** : Optional[str]

  Delimiter to use; defaults to comma.

- **delimiter** : Optional[str]

  Alternative delimiter to use.

- **dtype** : Optional[Dict[str, str]], Optional[List[str]]

  Data types for columns.

- **na_values** : Optional[str], Optional[List[str]]

  Additional strings to recognize as NA/NaN.

- **skiprows** : Optional[int]

  Number of rows to skip at the start.

- **quotechar** : Optional[str]

  Character used to quote fields.

- **escapechar** : Optional[str]

  Character used to escape delimiter or quote characters.

- **encoding** : Optional[str]

  Encoding to use for UTF when reading/writing.

- **parallel** : Optional[bool]

  Enable parallel reading.

- **date_format** : Optional[str]

  Format to parse dates.

- **timestamp_format** : Optional[str]

  Format to parse timestamps.

- **sample_size** : Optional[int]

  Number of rows to sample for schema inference.

- **all_varchar** : Optional[bool]

  Treat all columns as VARCHAR.

- **normalize_names** : Optional[bool]

  Normalize column names to lowercase.

- **null_padding** : Optional[bool]

  Enable null padding for rows with missing columns.

- **names** : Optional[List[str]]

  List of column names to use.

- **lineterminator** : Optional[str]

  Character to break lines on.

- **columns** : Optional[Dict[str, str]]

  Column mapping for schema.

- **auto_type_candidates** : Optional[List[str]]

  List of columns for automatic type inference.

- **max_line_size** : Optional[int]

  Maximum line size in bytes.

- **ignore_errors** : Optional[bool]

  Ignore parsing errors.

- **store_rejects** : Optional[bool]

  Store rejected rows.

- **rejects_table** : Optional[str]

  Table name to store rejected rows.

- **rejects_scan** : Optional[str]

  Scan to use for rejects.

- **rejects_limit** : Optional[int]

  Limit number of rejects stored.

- **force_not_null** : Optional[List[str]]

  List of columns to force as NOT NULL.

- **buffer_size** : Optional[int]

  Buffer size in bytes.

- **decimal** : Optional[str]

  Character to recognize as decimal point.

- **allow_quoted_nulls** : Optional[bool]

  Allow quoted NULL values.

- **filename** : Optional[bool], Optional[str]

  Add filename column or specify filename.

- **hive_partitioning** : Optional[bool]

  Enable Hive-style partitioning.

- **union_by_name** : Optional[bool]

  Union files by column name instead of position.

- **hive_types** : Optional[Dict[str, str]]

  Hive types for columns.

- **hive_types_autocast** : Optional[bool]

  Automatically cast Hive types.

- **connection** : DuckDBPyConnection

  DuckDB connection to use.

Example

```
import csv
import duckdb

duckdb_conn = duckdb.connect()

with open('code_example.csv', 'w', newline='') as csvfile:
    fieldnames = ['id', 'text']
    writer = csv.DictWriter(csvfile, fieldnames=fieldnames)
    writer.writeheader()
    writer.writerow({'id': '1', 'text': 'a'})
```

```
rel = duckdb_conn.from_csv_auto("code_example.csv")

rel.show()
```

Result

id int64	text varchar
1	a

`from_df`

Signature

```
from_df(self: _duckdb.DuckDBPyConnection, df: pandas.DataFrame) -> _duckdb.DuckDBPyRelation
```

Description Create a relation object from the DataFrame in df

Parameters

- **df** : pandas.DataFrame

  A pandas DataFrame to be converted into a DuckDB relation.

Example

```
import duckdb
import pandas as pd

df = pd.DataFrame(data = {'id': [1], "text":["a"]})

duckdb_conn = duckdb.connect()

rel = duckdb_conn.from_df(df)

rel.show()
```

Result

id int64	text varchar
1	a

`from_parquet`

Signature

```
from_parquet(*args, **kwargs)
Overloaded function.

1. from_parquet(self: _duckdb.DuckDBPyConnection, file_glob: str, binary_as_string: bool = False, *, file_row_number: bool = False, filename: bool = False, hive_partitioning: bool = False, union_by_name: bool = False, compression: object = None) -> _duckdb.DuckDBPyRelation

Create a relation object from the Parquet files in file_glob

2. from_parquet(self: _duckdb.DuckDBPyConnection, file_globs: collections.abc.Sequence[str], binary_as_string: bool = False, *, file_row_number: bool = False, filename: bool = False, hive_partitioning: bool = False, union_by_name: bool = False, compression: object = None) -> _duckdb.DuckDBPyRelation

Create a relation object from the Parquet files in file_globs
```

Description Create a relation object from the Parquet files

Aliases: `read_parquet`

Parameters

- **file_glob** : str

  File path or glob pattern pointing to Parquet files to be read.

- **binary_as_string** : bool, default: False

  Interpret binary columns as strings instead of blobs.

- **file_row_number** : bool, default: False

  Add a column containing the row number within each file.

- **filename** : bool, default: False

  Add a column containing the name of the file each row came from.

- **hive_partitioning** : bool, default: False

  Enable automatic detection of Hive-style partitions in file paths.

- **union_by_name** : bool, default: False

  Union Parquet files by matching column names instead of positions.

- **compression** : object

  Optional compression codec to use when reading the Parquet files.

Example

```
import duckdb
import pyarrow as pa
import pyarrow.parquet as pq

ids = pa.array([1], type=pa.int8())
texts = pa.array(['a'], type=pa.string())
example_table = pa.table([ids, texts], names=["id", "text"])

pq.write_table(example_table, "code_example.parquet")

duckdb_conn = duckdb.connect()
```

```
rel = duckdb_conn.from_parquet("code_example.parquet")

rel.show()
```

Result

id int8	text varchar
1	a

`from_query`

Signature

```
from_query(self: _duckdb.DuckDBPyConnection, query: object, *, alias: str = '', params: object = None)
-> _duckdb.DuckDBPyRelation
```

Description Run a SQL query. If it is a SELECT statement, create a relation object from the given SQL query, otherwise run the query as-is.

> **Warning.** Passing `params` to this method is discouraged due to significant performance overhead. Use `execute()` for parameterized queries instead.

Aliases: `query`, `sql`

Parameters

- **query** : object

  The SQL query or subquery to be executed and converted into a relation.

- **alias** : str, default: ''

  Optional alias name to assign to the resulting relation.

- **params** : object

  Optional query parameters. **Discouraged** due to significant performance overhead. Use `execute()` for parameterized queries instead.

Example

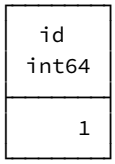
```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.from_query("from range(1,2) tbl(id)")

rel.show()
```

Result



id
int64
1

---

query

Signature

```
query(self: _duckdb.DuckDBPyConnection, query: object, *, alias: str = '', params: object = None) -> _duckdb.DuckDBPyRelation
```

Description Run a SQL query. If it is a SELECT statement, create a relation object from the given SQL query, otherwise run the query as-is.

> **Warning.** Passing `params` to this method is discouraged due to significant performance overhead. Use `execute()` for parameterized queries instead.

Aliases: `from_query`, `sql`

Parameters

- **query** : object

  The SQL query or subquery to be executed and converted into a relation.

- **alias** : str, default: ''

  Optional alias name to assign to the resulting relation.

- **params** : object

  Optional query parameters. **Discouraged** due to significant performance overhead. Use `execute()` for parameterized queries instead.

Example

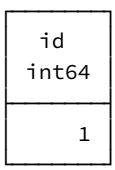
```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.query("from range(1,2) tbl(id)")

rel.show()
```

Result



id
int64
1

`read_csv`

Signature

```
read_csv(self: _duckdb.DuckDBPyConnection, path_or_buffer: object, **kwargs) -> _duckdb.DuckDBPyRelation
```

Description Create a relation object from the CSV file in 'name'

Aliases: `from_csv_auto`

Parameters

- **path_or_buffer** : Union[str, StringIO, TextIOBase]

  Path to the CSV file or buffer to read from.

- **header** : Optional[bool], Optional[int]

  Row number(s) to use as the column names, or None if no header.

- **compression** : Optional[str]

  Compression type (e.g., 'gzip', 'bz2').

- **sep** : Optional[str]

  Delimiter to use; defaults to comma.

- **delimiter** : Optional[str]

  Alternative delimiter to use.

- **dtype** : Optional[Dict[str, str]], Optional[List[str]]

  Data types for columns.

- **na_values** : Optional[str], Optional[List[str]]

  Additional strings to recognize as NA/NaN.

- **skiprows** : Optional[int]

  Number of rows to skip at the start.

- **quotechar** : Optional[str]

  Character used to quote fields.

- **escapechar** : Optional[str]

  Character used to escape delimiter or quote characters.

- **encoding** : Optional[str]

  Encoding to use for UTF when reading/writing.

- **parallel** : Optional[bool]

  Enable parallel reading.

- **date_format** : Optional[str]

  Format to parse dates.

- **timestamp_format** : Optional[str]

  Format to parse timestamps.

- **sample_size** : Optional[int]

  Number of rows to sample for schema inference.

- **all_varchar** : Optional[bool]

  Treat all columns as VARCHAR.

- **normalize_names** : Optional[bool]

  Normalize column names to lowercase.

- **null_padding** : Optional[bool]

  Enable null padding for rows with missing columns.

- **names** : Optional[List[str]]

  List of column names to use.

- **lineterminator** : Optional[str]

  Character to break lines on.

- **columns** : Optional[Dict[str, str]]

  Column mapping for schema.

- **auto_type_candidates** : Optional[List[str]]

  List of columns for automatic type inference.

- **max_line_size** : Optional[int]

  Maximum line size in bytes.

- **ignore_errors** : Optional[bool]

  Ignore parsing errors.

- **store_rejects** : Optional[bool]

  Store rejected rows.

- **rejects_table** : Optional[str]

  Table name to store rejected rows.

- **rejects_scan** : Optional[str]

  Scan to use for rejects.

- **rejects_limit** : Optional[int]

  Limit number of rejects stored.

- **force_not_null** : Optional[List[str]]

  List of columns to force as NOT NULL.

- **buffer_size** : Optional[int]

  Buffer size in bytes.

- **decimal** : Optional[str]

  Character to recognize as decimal point.

- **allow_quoted_nulls** : Optional[bool]

  Allow quoted NULL values.

- **filename** : Optional[bool], Optional[str]

  Add filename column or specify filename.

- **hive_partitioning** : Optional[bool]

  Enable Hive-style partitioning.

- **union_by_name** : Optional[bool]

  Union files by column name instead of position.

- **hive_types** : Optional[Dict[str, str]]

  Hive types for columns.

- **hive_types_autocast** : Optional[bool]

  Automatically cast Hive types.

- **connection** : DuckDBPyConnection

  DuckDB connection to use.

Example

```
import csv
import duckdb

duckdb_conn = duckdb.connect()

with open('code_example.csv', 'w', newline='') as csvfile:
    fieldnames = ['id', 'text']
    writer = csv.DictWriter(csvfile, fieldnames=fieldnames)
    writer.writeheader()
    writer.writerow({'id': '1', 'text': 'a'})

rel = duckdb_conn.read_csv("code_example.csv")

rel.show()
```

Result

id	text
int64	varchar
1	a

`read_json`

Signature

```
read_json(self: _duckdb.DuckDBPyConnection, path_or_buffer: object, *, columns: typing.Optional[object]
= None, sample_size: typing.Optional[object] = None, maximum_depth: typing.Optional[object] = None,
records: typing.Optional[str] = None, format: typing.Optional[str] = None, date_format:
typing.Optional[object] = None, timestamp_format: typing.Optional[object] = None, compression:
typing.Optional[object] = None, maximum_object_size: typing.Optional[object] = None, ignore_errors:
typing.Optional[object] = None, convert_strings_to_integers: typing.Optional[object] = None, field_
appearance_threshold: typing.Optional[object] = None, map_inference_threshold: typing.Optional[object] =
None, maximum_sample_files: typing.Optional[object] = None, filename: typing.Optional[object] = None,
hive_partitioning: typing.Optional[object] = None, union_by_name: typing.Optional[object] = None, hive_
types: typing.Optional[object] = None, hive_types_autocast: typing.Optional[object] = None) -> _
duckdb.DuckDBPyRelation
```

Description Create a relation object from the JSON file in 'name'

Parameters

- **path_or_buffer** : object

  File path or file-like object containing JSON data to be read.

- **columns** : object

  Optional list of column names to project from the JSON data.

- **sample_size** : object

  Number of rows to sample for inferring JSON schema.

- **maximum_depth** : object

  Maximum depth to which JSON objects should be parsed.

- **records** : str

  Format string specifying whether JSON is in records mode.

- **format** : str

  Format of the JSON data (e.g., 'auto', 'newline_delimited').

- **date_format** : object

  Format string for parsing date fields.

- **timestamp_format** : object

  Format string for parsing timestamp fields.

- **compression** : object

  Compression codec used on the JSON data (e.g., 'gzip').

- **maximum_object_size** : object

  Maximum size in bytes for individual JSON objects.

- **ignore_errors** : object

  If True, skip over JSON records with parsing errors.

- **convert_strings_to_integers** : object

  If True, attempt to convert strings to integers where appropriate.

- **field_appearance_threshold** : object

  Threshold for inferring optional fields in nested JSON.

- **map_inference_threshold** : object

  Threshold for inferring maps from JSON object patterns.

- **maximum_sample_files** : object

  Maximum number of files to sample for schema inference.

- **filename** : object

  If True, include a column with the source filename for each row.

- **hive_partitioning** : object

  If True, enable Hive partitioning based on directory structure.

- **union_by_name** : object

  If True, align JSON columns by name instead of position.

- **hive_types** : object

  If True, use Hive types from directory structure for schema.

- **hive_types_autocast** : object

  If True, automatically cast data types to match Hive types.

Example

```
import duckdb
import json

with open("code_example.json", mode="w") as f:
    json.dump([{'id': 1, "text":"a"}], f)

duckdb_conn = duckdb.connect()

rel = duckdb_conn.read_json("code_example.json")

rel.show()
```

Result

id int64	text varchar
1	a

`read_parquet`

Signature

```
read_parquet(*args, **kwargs)
Overloaded function.

1. read_parquet(self: _duckdb.DuckDBPyConnection, file_glob: str, binary_as_string: bool = False, *,
file_row_number: bool = False, filename: bool = False, hive_partitioning: bool = False, union_by_name:
bool = False, compression: object = None) -> _duckdb.DuckDBPyRelation
```

```
Create a relation object from the Parquet files in file_glob

2. read_parquet(self: _duckdb.DuckDBPyConnection, file_globs: collections.abc.Sequence[str], binary_as_
string: bool = False, *, file_row_number: bool = False, filename: bool = False, hive_partitioning: bool
= False, union_by_name: bool = False, compression: object = None) -> _duckdb.DuckDBPyRelation

Create a relation object from the Parquet files in file_globs
```

Description Create a relation object from the Parquet files

Aliases: `from_parquet`

Parameters

- **file_glob** : str

  File path or glob pattern pointing to Parquet files to be read.

- **binary_as_string** : bool, default: False

  Interpret binary columns as strings instead of blobs.

- **file_row_number** : bool, default: False

  Add a column containing the row number within each file.

- **filename** : bool, default: False

  Add a column containing the name of the file each row came from.

- **hive_partitioning** : bool, default: False

  Enable automatic detection of Hive-style partitions in file paths.

- **union_by_name** : bool, default: False

  Union Parquet files by matching column names instead of positions.

- **compression** : object

  Optional compression codec to use when reading the Parquet files.

Example

```
import duckdb
import pyarrow as pa
import pyarrow.parquet as pq

ids = pa.array([1], type=pa.int8())
texts = pa.array(['a'], type=pa.string())
example_table = pa.table([ids, texts], names=["id", "text"])

pq.write_table(example_table, "code_example.parquet")

duckdb_conn = duckdb.connect()

rel = duckdb_conn.read_parquet("code_example.parquet")

rel.show()
```

Result

id int8	text varchar
1	a

---

sql

Signature

```
sql(self: _duckdb.DuckDBPyConnection, query: object, *, alias: str = '', params: object = None) -> _
duckdb.DuckDBPyRelation
```

Description Run a SQL query. If it is a SELECT statement, create a relation object from the given SQL query, otherwise run the query as-is.

> **Warning.** Passing `params` to this method is discouraged due to significant performance overhead. Use `execute()` for parameterized queries instead.

Aliases: `from_query`, `query`

Parameters

- **query** : object

  The SQL query or subquery to be executed and converted into a relation.

- **alias** : str, default: ''

  Optional alias name to assign to the resulting relation.

- **params** : object

  Optional query parameters. **Discouraged** due to significant performance overhead. Use `execute()` for parameterized queries instead.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("from range(1,2) tbl(id)")

rel.show()
```

Result

id int64
1

`table`

Signature

```
table(self: _duckdb.DuckDBPyConnection, table_name: str) -> _duckdb.DuckDBPyRelation
```

Description Create a relation object for the named table

Parameters

- **table_name** : str

  Name of the table to create a relation from.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

duckdb_conn.sql("create table code_example as select * from range(1,2) tbl(id)")

rel = duckdb_conn.table("code_example")

rel.show()
```

Result

```
┌─────────┐
│   id    │
│  int64  │
├─────────┤
│       1 │
└─────────┘
```

`table_function`

Signature

```
table_function(self: _duckdb.DuckDBPyConnection, name: str, parameters: object = None) -> _
duckdb.DuckDBPyRelation
```

Description Create a relation object from the named table function with given parameters

Parameters

- **name** : str

  Name of the table function to call.

- **parameters** : object

  Optional parameters to pass to the table function.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

duckdb_conn.sql("""
    create macro get_record_for(x) as table
    select x*range from range(1,2)
""")

rel = duckdb_conn.table_function(name="get_record_for", parameters=[1])

rel.show()
```

Result

```
┌──────────────┐
│ (1 * "range") │
│    int64     │
├──────────────┤
│            1 │
└──────────────┘
```

---

values

Signature

```
values(self: _duckdb.DuckDBPyConnection, *args) -> _duckdb.DuckDBPyRelation
```

Description Create a relation object from the passed values

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.values([1, 'a'])

rel.show()
```

Result

```
┌─────────┬─────────┐
│  col0   │  col1   │
│  int32  │ varchar │
├─────────┼─────────┤
│       1 │ a       │
└─────────┴─────────┘
```

---

view

Signature

```
view(self: _duckdb.DuckDBPyConnection, view_name: str) -> _duckdb.DuckDBPyRelation
```

Description Create a relation object for the named view

Parameters

- **view_name** : str

  Name of the view to create a relation from.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

duckdb_conn.sql("create table code_example as select * from range(1,2) tbl(id)")

rel = duckdb_conn.view("code_example")

rel.show()
```

Result

```
┌─────────┐
│   id    │
│  int64  │
├─────────┤
│       1 │
└─────────┘
```

Relation Definition Details

This section contains the details on how to inspect a relation.

Name	Description
`alias`	Get the name of the current alias
`columns`	Return a list containing the names of the columns of the relation.
`describe`	Gives basic statistics (e.g., min, max) and if NULL exists for each column of the relation.
`description`	Return the description of the result
`dtypes`	Return a list containing the types of the columns of the relation.
`explain`	explain(self: _duckdb.DuckDBPyRelation, type: _duckdb.ExplainType = 'standard') -> str
`query`	Run the given SQL query in sql_query on the view named virtual_table_name that refers to the relation object
`set_alias`	Rename the relation object to new alias
`shape`	Tuple of # of rows, # of columns in relation.
`show`	Display a summary of the data
`sql_query`	Get the SQL query that is equivalent to the relation

Name	Description
`type`	Get the type of the relation.
`types`	Return a list containing the types of the columns of the relation.

`alias`

Description Get the name of the current alias

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.alias
```

Result

```
unnamed_relation_43c808c247431be5
```

`columns`

Description Return a list containing the names of the columns of the relation.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.columns
```

Result

```
['id', 'description', 'value', 'created_timestamp']
```

---

describe

Signature

```
describe(self: _duckdb.DuckDBPyRelation) -> _duckdb.DuckDBPyRelation
```

Description Gives basic statistics (e.g., min, max) and if NULL exists for each column of the relation.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.describe()
```

Result

```
┌─────────┬──────────────────────────────────────┬──────────────┬────────────────────┬──────────────────────────┐
│  aggr   │                  id                  │ description  │       value        │ created_timestamp        │
│ varchar │               varchar                │   varchar    │       double       │         varchar          │
├─────────┼──────────────────────────────────────┼──────────────┼────────────────────┼──────────────────────────┤

│ max     │ fb10390e-fad5-4694-91cb-e82728cb6f9f │ value is uneven│              9.0 │ 2025-04-09 15:49:20.642+02 │
│ median  │ NULL                                 │ NULL         │                5.0 │ NULL                     │
└─────────┴──────────────────────────────────────┴──────────────┴────────────────────┴──────────────────────────┘
```

---

description

Description Return the description of the result

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.description
```

Result

```
[('id', 'UUID', None, None, None, None, None),
 ('description', 'STRING', None, None, None, None, None),
 ('value', 'NUMBER', None, None, None, None, None),
 ('created_timestamp', 'DATETIME', None, None, None, None, None)]
```

---

dtypes

Description Return a list containing the types of the columns of the relation.

Aliases: `types`

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.dtypes
```

Result

```
[UUID, VARCHAR, BIGINT, TIMESTAMP WITH TIME ZONE]
```

---

explain

Description explain(self: _duckdb.DuckDBPyRelation, type: _duckdb.ExplainType = 'standard') -> str

Example

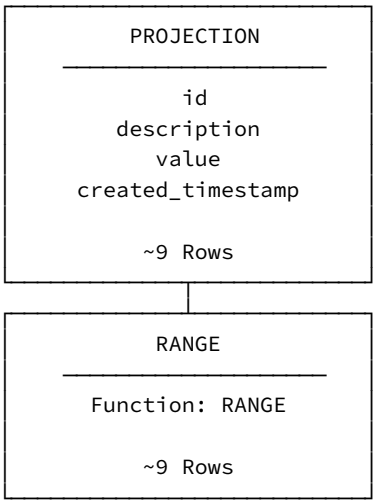
```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.explain()
```

Result



---

query

Signature

```
query(self: _duckdb.DuckDBPyRelation, virtual_table_name: str, sql_query: str) -> _
duckdb.DuckDBPyRelation
```

Description Run the given SQL query in sql_query on the view named virtual_table_name that refers to the relation object

Parameters

- **virtual_table_name** : str

  The name to assign to the current relation when referenced in the SQL query.

- **sql_query** : str

  The SQL query string that uses the virtual table name to query the relation.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.query(virtual_table_name="rel_view", sql_query="from rel")

duckdb_conn.sql("show rel_view")
```

Result

column_name varchar	column_type varchar	null varchar	key varchar	default varchar	extra varchar
id	UUID	YES	NULL	NULL	NULL
description	VARCHAR	YES	NULL	NULL	NULL
value	BIGINT	YES	NULL	NULL	NULL
created_timestamp	TIMESTAMP WITH TIME ZONE	YES	NULL	NULL	NULL

---

set_alias

Signature

```
set_alias(self: _duckdb.DuckDBPyRelation, alias: str) -> _duckdb.DuckDBPyRelation
```

Description Rename the relation object to new alias

Parameters

- **alias** : str

  The alias name to assign to the relation.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.set_alias('abc').select('abc.id')
```

Result

```
In the SQL query, the alias will be `abc`
```

---

shape

Description Tuple of # of rows, # of columns in relation.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.shape
```

Result

```
(9, 4)
```

---

show

Signature

```
show(self: _duckdb.DuckDBPyRelation, *, max_width: typing.Optional[typing.SupportsInt] = None, max_rows:
typing.Optional[typing.SupportsInt] = None, max_col_width: typing.Optional[typing.SupportsInt] = None,
null_value: typing.Optional[str] = None, render_mode: object = None) -> None
```

Description Display a summary of the data

Parameters

- **max_width** : int

  Maximum display width for the entire output in characters.

- **max_rows** : int

  Maximum number of rows to display.

- **max_col_width** : int

  Maximum number of characters to display per column.

- **null_value** : str

  String to display in place of NULL values.

- **render_mode** : object

  Render mode for displaying the output.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.show()
```

Result

id uuid	description varchar	value int64	created_timestamp timestamp with time zone
642ea3d7-793d-4867-a759-91c1226c25a0	value is uneven	1	2025-04-09 15:41:20.642+02

```

---

sql_query

Signature

```
sql_query(self: _duckdb.DuckDBPyRelation) -> str
```

Description Get the SQL query that is equivalent to the relation

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.sql_query()
```

Result

```
SELECT
    gen_random_uuid() AS id,
    concat('value is ', CASE  WHEN ((mod("range", 2) = 0)) THEN ('even') ELSE 'uneven' END) AS
    description,
    "range" AS "value",
    (now() + CAST(concat("range", ' ', 'minutes') AS INTERVAL)) AS created_timestamp
FROM "range"(1, 10)
```

---

type

Description Get the type of the relation.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
```

```
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.type
```

Result

```
QUERY_RELATION
```

---

types

Description Return a list containing the types of the columns of the relation.

Aliases: `dtypes`

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.types
```

Result

```
[UUID, VARCHAR, BIGINT, TIMESTAMP WITH TIME ZONE]
```

Transformation

This section contains the methods which can be used to chain queries. The methods are lazy evaluated.

Name	Description
`aggregate`	Compute the aggregate aggr_expr by the optional groups group_expr on the relation
`apply`	Compute the function of a single column or a list of columns by the optional groups on the relation

Name	Description
`cross`	Create cross/cartesian product of two relational objects
`except_`	Create the set except of this relation object with another relation object in other_rel
`filter`	Filter the relation object by the filter in filter_expr
`insert`	Inserts the given values into the relation
`insert_into`	Inserts the relation object into an existing table named table_name
`intersect`	Create the set intersection of this relation object with another relation object in other_rel
`join`	Join the relation object with another relation object in other_rel using the join condition expression in join_condition. Types supported are 'inner', 'left', 'right', 'outer', 'semi' and 'anti'
`limit`	Only retrieve the first n rows from this relation object, starting at offset
`map`	Calls the passed function on the relation
`order`	Reorder the relation object by order_expr
`project`	Project the relation object by the projection in project_expr
`select`	Project the relation object by the projection in project_expr
`sort`	Reorder the relation object by the provided expressions
`union`	Create the set union of this relation object with another relation object in other_rel
`update`	Update the given relation with the provided expressions

`aggregate`

Signature

```
aggregate(self: _duckdb.DuckDBPyRelation, aggr_expr: object, group_expr: str = '') -> _
duckdb.DuckDBPyRelation
```

Description Compute the aggregate aggr_expr by the optional groups group_expr on the relation

Parameters

- **aggr_expr** : str, list[Expression]

  The list of columns and aggregation functions.

- **group_expr** : str, default: ''

  The list of columns to be included in `group_by`. If None, `group by all` is applied.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
```

```
        from range(1, 10)
    """
)

rel = rel.aggregate('max(value)')
```

Result

```
┌──────────────┐
│ max("value") │
│    int64     │
├──────────────┤
│            9 │
└──────────────┘
```

---

apply

Signature

```
apply(self: _duckdb.DuckDBPyRelation, function_name: str, function_aggr: str, group_expr: str = '',
function_parameter: str = '', projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Compute the function of a single column or a list of columns by the optional groups on the relation

Parameters

- **function_name** : str

  Name of the function to apply over the relation.

- **function_aggr** : str

  The list of columns to apply the function over.

- **group_expr** : str, default: ''

  Optional SQL expression for grouping.

- **function_parameter** : str, default: ''

  Optional parameters to pass into the function.

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
```

```
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.apply(
    function_name="count",
    function_aggr="id",
    group_expr="description",
    projected_columns="description"
)
```

Result

description varchar	count(id) int64
value is uneven	5
value is even	4

---

cross

Signature

```
cross(self: _duckdb.DuckDBPyRelation, other_rel: _duckdb.DuckDBPyRelation) -> _duckdb.DuckDBPyRelation
```

Description Create cross/cartesian product of two relational objects

Parameters

- **other_rel** : _duckdb.DuckDBPyRelation

  Another relation to perform a cross product with.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.cross(other_rel=rel.set_alias("other_rel"))
```

Result

```
┌──────────────────────────────────────┬──────────────────┬─────────┬──────────────────────────────────────┬──────────────────
│                  id                  │   description    │ value │     created_timestamp      │                  id
│   description    │ value │     created_timestamp      │

...
```

---

except_

Signature

```
except_(self: _duckdb.DuckDBPyRelation, other_rel: _duckdb.DuckDBPyRelation) -> _duckdb.DuckDBPyRelation
```

Description Create the set except of this relation object with another relation object in other_rel

Parameters

- **other_rel** : _duckdb.DuckDBPyRelation

  The relation to subtract from the current relation (set difference).

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.except_(other_rel=rel.set_alias("other_rel"))
```

Result

The relation query is executed twice, therefore generating different ids and timestamps:

id uuid	description varchar	value int64	created_timestamp timestamp with time zone
f69ed6dd-a7fe-4de2-b6af-1c2418096d69	value is uneven	3	2025-04-10 11:43:05.711+02
08ad11dc-a9c2-4aaa-9272-760b27ad1f5d	value is uneven	7	2025-04-10 11:47:05.711+02

...

`filter`

Signature

```
filter(self: _duckdb.DuckDBPyRelation, filter_expr: object) -> _duckdb.DuckDBPyRelation
```

Description Filter the relation object by the filter in filter_expr

Parameters

- **filter_expr** : str, Expression

  The filter expression to apply over the relation.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.filter("value = 2")
```

Result

id uuid	description varchar	value int64	created_timestamp timestamp with time zone
b0684ab7-fcbf-41c5-8e4a-a51bdde86926	value is even	2	2025-04-10 09:54:29.78+02

`insert`

Signature

```
insert(self: _duckdb.DuckDBPyRelation, values: object) -> None
```

Description Inserts the given values into the relation

Parameters

- **values** : object

  A tuple of values matching the relation column list, to be inserted.

Example

```
import duckdb

from datetime import datetime
from uuid import uuid4

duckdb_conn = duckdb.connect()

duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
).to_table("code_example")

rel = duckdb_conn.table("code_example")

rel.insert(
    (
        uuid4(),
        'value is even',
        10,
        datetime.now()
    )
)

rel.filter("value = 10")
```

Result

id uuid	description varchar	value int64	created_timestamp timestamp with time zone
c6dfab87-fae6-4213-8f76-1b96a8d179f6	value is even	10	2025-04-10 10:02:24.652218+02

`insert_into`

Signature

```
insert_into(self: _duckdb.DuckDBPyRelation, table_name: str) -> None
```

Description Inserts the relation object into an existing table named table_name

Parameters

- **table_name** : str

  The table name to insert the data into. The relation must respect the column order of the table.

Example

```
import duckdb

from datetime import datetime
from uuid import uuid4

duckdb_conn = duckdb.connect()

duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
).to_table("code_example")

rel = duckdb_conn.values(
    [
        uuid4(),
        'value is even',
        10,
        datetime.now()
    ]
)

rel.insert_into("code_example")

duckdb_conn.table("code_example").filter("value = 10")
```

Result

id uuid	description varchar	value int64	created_timestamp timestamp with time zone
271c5ddd-c1d5-4638-b5a0-d8c7dc9e8220	value is even	10	2025-04-10 14:29:18.616379+02

`intersect`

Signature

```
intersect(self: _duckdb.DuckDBPyRelation, other_rel: _duckdb.DuckDBPyRelation) -> _
duckdb.DuckDBPyRelation
```

Description Create the set intersection of this relation object with another relation object in other_rel

Parameters

- **other_rel** : _duckdb.DuckDBPyRelation

  The relation to intersect with the current relation (set intersection).

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.intersect(other_rel=rel.set_alias("other_rel"))
```

Result

```
The relation query is executed once with `rel` and once with `other_rel`,
therefore generating different ids and timestamps:
```

id uuid	description varchar	value int64	created_timestamp timestamp with time zone
0 rows			

---

join

Signature

```
join(self: _duckdb.DuckDBPyRelation, other_rel: _duckdb.DuckDBPyRelation, condition: object, how: str =
'inner') -> _duckdb.DuckDBPyRelation
```

Description Join the relation object with another relation object in other_rel using the join condition expression in join_condition. Types supported are 'inner', 'left', 'right', 'outer', 'semi' and 'anti'

Depending on how the `condition` parameter is provided, the JOIN clause generated is:

- USING

```
import duckdb

duckdb_conn = duckdb.connect()

rel1 = duckdb_conn.sql("select range as id, concat('dummy 1', range) as text from range(1,10)")
rel2 = duckdb_conn.sql("select range as id, concat('dummy 2', range) as text from range(5,7)")

rel1.join(rel2, condition="id", how="inner").sql_query()
```

with following SQL:

```
SELECT *
FROM (
        SELECT "range" AS id,
```

```
            concat('dummy 1', "range") AS "text"
        FROM "range"(1, 10)
    ) AS unnamed_relation_41bc15e744037078
INNER JOIN (
        SELECT "range" AS id,
        concat('dummy 2', "range") AS "text"
        FROM "range"(5, 7)
    ) AS unnamed_relation_307e245965aa2c2b
USING (id)
```

- ON

```
import duckdb

duckdb_conn = duckdb.connect()

rel1 = duckdb_conn.sql("select range as id, concat('dummy 1', range) as text from range(1,10)")
rel2 = duckdb_conn.sql("select range as id, concat('dummy 2', range) as text from range(5,7)")

rel1.join(rel2, condition=f"{rel1.alias}.id = {rel2.alias}.id", how="inner").sql_query()
```

with the following SQL:

```
SELECT *
FROM (
        SELECT "range" AS id,
            concat('dummy 1', "range") AS "text"
        FROM "range"(1, 10)
    ) AS unnamed_relation_41bc15e744037078
INNER JOIN (
        SELECT "range" AS id,
        concat('dummy 2', "range") AS "text"
        FROM "range"(5, 7)
    ) AS unnamed_relation_307e245965aa2c2b
ON ((unnamed_relation_41bc15e744037078.id = unnamed_relation_307e245965aa2c2b.id))
```

> NATURAL, POSITIONAL and ASOF joins are not provided by the relational API. CROSS joins are provided through the cross method.

Parameters

- **other_rel** : _duckdb.DuckDBPyRelation

  The relation to join with the current relation.

- **condition** : object

  The join condition, typically a SQL expression or the duplicated column name to join on.

- **how** : str, default: 'inner'

  The type of join to perform: 'inner', 'left', 'right', 'outer', 'semi' and 'anti'.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
```

```
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel = rel.set_alias("rel").join(
    other_rel=rel.set_alias("other_rel"),
    condition="rel.id = other_rel.id",
    how="left"
)

rel.count("*")
```

Result

```
┌──────────────┐
│ count_star() │
│    int64     │
├──────────────┤
│            9 │
└──────────────┘
```

`limit`

Signature

```
limit(self: _duckdb.DuckDBPyRelation, n: typing.SupportsInt, offset: typing.SupportsInt = 0) -> _
duckdb.DuckDBPyRelation
```

Description Only retrieve the first n rows from this relation object, starting at offset

Parameters

- **n** : int

  The maximum number of rows to return.

- **offset** : int, default: 0

  The number of rows to skip before starting to return rows.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
```

```
    """
)

rel.limit(1)
```

Result

id uuid	description varchar	value int64	created_timestamp timestamp with time zone
4135597b-29e7-4cb9-a443-41f3d54f25df	value is uneven	1	2025-04-10 10:52:03.678+02

---

map

Signature

```
map(self: _duckdb.DuckDBPyRelation, map_function: collections.abc.Callable, *, schema:
typing.Optional[object] = None) -> _duckdb.DuckDBPyRelation
```

Description Calls the passed function on the relation

Parameters

- **map_function** : Callable

  A Python function that takes a DataFrame and returns a transformed DataFrame.

- **schema** : object, default: None

  Optional schema describing the structure of the output relation.

Example

```
import duckdb
from pandas import DataFrame

def multiply_by_2(df: DataFrame):
    df["id"] = df["id"] * 2
    return df

duckdb_conn = duckdb.connect()
rel = duckdb_conn.sql("select range as id, 'dummy' as text from range(1,3)")

rel.map(multiply_by_2, schema={"id": int, "text": str})
```

Result

id int64	text varchar
2	dummy
4	dummy

`order`

Signature

```
order(self: _duckdb.DuckDBPyRelation, order_expr: str) -> _duckdb.DuckDBPyRelation
```

Description Reorder the relation object by order_expr

Parameters

- **order_expr** : str

  SQL expression defining the ordering of the result rows.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.order("value desc").limit(1, offset=4)
```

Result

id uuid	description varchar	value int64	created_timestamp timestamp with time zone
55899131-e3d3-463c-a215-f65cb8aef3bf	value is uneven	5	2025-04-10 10:56:03.678+02

`project`

Signature

```
project(self: _duckdb.DuckDBPyRelation, *args, groups: str = '') -> _duckdb.DuckDBPyRelation
```

Description Project the relation object by the projection in project_expr

Aliases: `select`

Parameters

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.project("description").limit(1)
```

Result

```
┌──────────────────┐
│   description    │
│     varchar      │
├──────────────────┤
│ value is uneven  │
└──────────────────┘
```

`select`

Signature

```
select(self: _duckdb.DuckDBPyRelation, *args, groups: str = '') -> _duckdb.DuckDBPyRelation
```

Description Project the relation object by the projection in project_expr

Aliases: `project`

Parameters

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.select("description").limit(1)
```

Result

description
varchar
value is uneven

---

sort

Signature

```
sort(self: _duckdb.DuckDBPyRelation, *args) -> _duckdb.DuckDBPyRelation
```

Description Reorder the relation object by the provided expressions

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.sort("description")
```

Result

id uuid	description varchar	value int64	created_timestamp timestamp with time zone
5e0dfa8c-de4d-4ccd-8cff-450dabb86bde	value is even	6	2025-04-10 16:52:15.605+02
95f1ad48-facf-4a84-a971-0a4fecce68c7	value is even	2	2025-04-10 16:48:15.605+02

...

---

union

Signature

```
union(self: _duckdb.DuckDBPyRelation, union_rel: _duckdb.DuckDBPyRelation) -> _duckdb.DuckDBPyRelation
```

Description Create the set union of this relation object with another relation object in other_rel

> The union is `union all`. In order to retrieve distinct values, apply distinct.

Parameters

- **union_rel** : _duckdb.DuckDBPyRelation

  The relation to union with the current relation (set union).

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel = rel.union(union_rel=rel)

rel.count("*")
```

Result

count_star() int64
18

---

update

Signature

```
update(self: _duckdb.DuckDBPyRelation, set: object, *, condition: object = None) -> None
```

Description Update the given relation with the provided expressions

Parameters

- **set** : object

  Mapping of columns to new values for the update operation.

- **condition** : object, default: None

  Optional condition to filter which rows to update.

Example

```
import duckdb

from duckdb import ColumnExpression

duckdb_conn = duckdb.connect()

duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
).to_table("code_example")

rel = duckdb_conn.table("code_example")

rel.update(set={"description":None}, condition=ColumnExpression("value") == 1)

# the update is executed on the table, but not reflected on the relationship
# the relationship has to be recreated to retrieve the modified data
rel = duckdb_conn.table("code_example")

rel.show()
```

Result

id uuid	description varchar	value int64	created_timestamp timestamp with time zone
66dcaa14-f4a6-4a55-af3b-7f6aa23ab4ad	NULL	1	2025-04-10 16:54:49.317+02
c6a18a42-67fb-4c95-827b-c966f2f95b88	value is even	2	2025-04-10 16:55:49.317+02

...

Functions

This section contains the functions which can be applied to a relation, in order to get a (scalar) result. The functions are lazy evaluated.

Name	Description
`any_value`	Returns the first non-null value from a given expression
`arg_max`	Finds the row with the maximum value for a value column and returns the value of that row for an argument column
`arg_min`	Finds the row with the minimum value for a value column and returns the value of that row for an argument column
`avg`	Computes the average of a given expression
`bit_and`	Computes the bitwise AND of all bits present in a given expression
`bit_or`	Computes the bitwise OR of all bits present in a given expression
`bit_xor`	Computes the bitwise XOR of all bits present in a given expression
`bitstring_agg`	Computes a bitstring with bits set for each distinct value in a given expression
`bool_and`	Computes the logical AND of all values present in a given expression
`bool_or`	Computes the logical OR of all values present in a given expression
`count`	Computes the number of elements present in a given expression
`cume_dist`	Computes the cumulative distribution within the partition
`dense_rank`	Computes the dense rank within the partition
`distinct`	Retrieve distinct rows from this relation object
`favg`	Computes the average of all values present in a given expression using a more accurate floating point summation (Kahan Sum)
`first`	Returns the first value of a given expression
`first_value`	Computes the first value within the group or partition
`fsum`	Computes the sum of all values present in a given expression using a more accurate floating point summation (Kahan Sum)
`geomean`	Computes the geometric mean over all values present in a given expression
`histogram`	Computes the histogram over all values present in a given expression
`lag`	Computes the lag within the partition
`last`	Returns the last value of a given expression
`last_value`	Computes the last value within the group or partition
`lead`	Computes the lead within the partition
`list`	Returns a list containing all values present in a given expression
`max`	Returns the maximum value present in a given expression
`mean`	Computes the average of a given expression
`median`	Computes the median over all values present in a given expression
`min`	Returns the minimum value present in a given expression
`mode`	Computes the mode over all values present in a given expression
`n_tile`	Divides the partition as equally as possible into num_buckets
`nth_value`	Computes the nth value within the partition
`percent_rank`	Computes the relative rank within the partition

Name	Description
`product`	Returns the product of all values present in a given expression
`quantile`	Computes the exact quantile value for a given expression
`quantile_cont`	Computes the interpolated quantile value for a given expression
`quantile_disc`	Computes the exact quantile value for a given expression
`rank`	Computes the rank within the partition
`rank_dense`	Computes the dense rank within the partition
`row_number`	Computes the row number within the partition
`select_dtypes`	Select columns from the relation, by filtering based on type(s)
`select_types`	Select columns from the relation, by filtering based on type(s)
`std`	Computes the sample standard deviation for a given expression
`stddev`	Computes the sample standard deviation for a given expression
`stddev_pop`	Computes the population standard deviation for a given expression
`stddev_samp`	Computes the sample standard deviation for a given expression
`string_agg`	Concatenates the values present in a given expression with a separator
`sum`	Computes the sum of all values present in a given expression
`unique`	Returns the distinct values in a column.
`value_counts`	Computes the number of elements present in a given expression, also projecting the original expression
`var`	Computes the sample variance for a given expression
`var_pop`	Computes the population variance for a given expression
`var_samp`	Computes the sample variance for a given expression
`variance`	Computes the sample variance for a given expression

`any_value`

Signature

```
any_value(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', window_spec: str = '',
projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Returns the first non-null value from a given expression

Parameters

- **column** : str

  The column name from which to retrieve any value.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`.

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select

arg_max

Signature

```
arg_max(self: _duckdb.DuckDBPyRelation, arg_column: str, value_column: str, groups: str = '', window_
spec: str = '', projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Finds the row with the maximum value for a value column and returns the value of that row for an argument column

Parameters

- **arg_column** : str

  The column name for which to find the argument maximizing the value.

- **value_column** : str

  The column name containing values used to determine the maximum.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`.

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.arg_max(arg_column="value", value_column="value", groups="description", projected_
columns="description")
```

Result

description varchar	arg_max("value", "value") int64
value is uneven	9
value is even	8

---

arg_min

Signature

```
arg_min(self: _duckdb.DuckDBPyRelation, arg_column: str, value_column: str, groups: str = '', window_
spec: str = '', projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Finds the row with the minimum value for a value column and returns the value of that row for an argument column

Parameters

- **arg_column** : str

  The column name for which to find the argument minimizing the value.

- **value_column** : str

  The column name containing values used to determine the minimum.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.arg_min(arg_column="value", value_column="value", groups="description", projected_
columns="description")
```

Result

description varchar	arg_min("value", "value") int64
value is even	2
value is uneven	1

---

avg

Signature

```
avg(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', window_spec: str = '', projected_
columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Computes the average of a given expression

Parameters

- **column** : str

  The column name to calculate the average on.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.avg('value')
```

Result

```
┌──────────────┐
│ avg("value") │
│    double    │
├──────────────┤
│          5.0 │
└──────────────┘
```

bit_and

Signature

```
bit_and(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', window_spec: str = '',
projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Computes the bitwise AND of all bits present in a given expression

Parameters

- **column** : str

  The column name to perform the bitwise AND aggregation on.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

value is uneven	0000000000000000000000000000000000000000000000000000000000000001
value is even	0000000000000000000000000000000000000000000000000000000000000000

`bit_or`

Signature

```
bit_or(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', window_spec: str = '',
projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Computes the bitwise OR of all bits present in a given expression

Parameters

- **column** : str

  The column name to perform the bitwise OR aggregation on.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""

value is even	00000000000000000000000000000000000000000000000000000000000001110

`bit_xor`

Signature

```
bit_xor(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', window_spec: str = '',
projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Computes the bitwise XOR of all bits present in a given expression

Parameters

- **column** : str

  The column name to perform the bitwise XOR aggregation on.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,

value is even	00000000000000000000000000000000000000000000000000000000000001000
value is uneven	00000000000000000000000000000000000000000000000000000000000001001

---

bitstring_agg

Signature

```
bitstring_agg(self: _duckdb.DuckDBPyRelation, expression: str, min: typing.Optional[object] = None, max:
typing.Optional[object] = None, groups: str = '', window_spec: str = '', projected_columns: str = '') ->
_duckdb.DuckDBPyRelation
```

Description Computes a bitstring with bits set for each distinct value in a given expression

Parameters

- **column** : str

  The column name to aggregate as a bitstring.

- **min** : object, default: None

  Optional minimum bitstring value for aggregation.

- **max** : object, default: None

  Optional maximum bitstring value for aggregation.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.bitstring_agg(column="value", groups="description", projected_columns="description", min=1, max=9)
```

bool_and

Signature

```
bool_and(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', window_spec: str = '',
projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Computes the logical AND of all values present in a given expression

Parameters

- **column** : str

  The column name to perform the boolean AND aggregation on.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel = rel.select("description, mod(value,2)::boolean as uneven")

rel.bool_and(column="uneven", groups="description", projected_columns="description")
```

Result

description varchar	bool_and(uneven) boolean
value is even	false
value is uneven	true

---

bool_or

Signature

```
bool_or(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', window_spec: str = '',
projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Computes the logical OR of all values present in a given expression

Parameters

- **column** : str

  The column name to perform the boolean OR aggregation on.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel = rel.select("description, mod(value,2)::boolean as uneven")

rel.bool_or(column="uneven", groups="description", projected_columns="description")
```

Result

description varchar	bool_or(uneven) boolean
value is even	false
value is uneven	true

---

count

Signature

```
count(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', window_spec: str = '',
projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Computes the number of elements present in a given expression

Parameters

- **column** : str

  The column name to perform count on.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

---

cume_dist

Signature

```
cume_dist(self: _duckdb.DuckDBPyRelation, window_spec: str, projected_columns: str = '') -> _
duckdb.DuckDBPyRelation
```

Description Computes the cumulative distribution within the partition

Parameters

- **window_spec** : str

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.cume_dist(window_spec="over (partition by description order by value)", projected_
columns="description, value")
```

Result

value is even	2	0.25
value is even	4	0.5
value is even	6	0.75
value is even	8	1.0

---

dense_rank

Signature

```
dense_rank(self: _duckdb.DuckDBPyRelation, window_spec: str, projected_columns: str = '') -> _
duckdb.DuckDBPyRelation
```

Description Computes the dense rank within the partition

Aliases: `rank_dense`

Parameters

- **window_spec** : str

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

 rel.dense_rank(window_spec="over (partition by description order by value)", projected_
columns="description, value")
```

Result

description varchar	value int64	dense_rank() OVER (PARTITION BY description ORDER BY "value") int64
value is even	2	1
value is even	4	2
value is even	6	3
value is even	8	4

value is uneven	5	3
value is uneven	7	4
value is uneven	9	5

---

distinct

Signature

```
distinct(self: _duckdb.DuckDBPyRelation) -> _duckdb.DuckDBPyRelation
```

Description Retrieve distinct rows from this relation object

Example

```
import duckdb

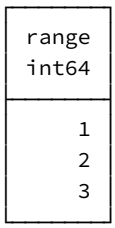
duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("select range from range(1,4)")

rel = rel.union(union_rel=rel)

rel.distinct().order("range")
```

Result



range
int64
1
2
3

`favg`

Signature

```
favg(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', window_spec: str = '',
projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Computes the average of all values present in a given expression using a more accurate floating point summation (Kahan Sum)

Parameters

- **column** : str

  The column name to calculate the average on.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.favg(column="value", groups="description", projected_columns="description")
```

Result

description varchar	favg("value") double
value is uneven	5.0
value is even	5.0

`first`

Signature

```
first(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', projected_columns: str = '') ->
_duckdb.DuckDBPyRelation
```

Description Returns the first value of a given expression

Parameters

- **column** : str

  The column name from which to retrieve the first value.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.first(column="value", groups="description", projected_columns="description")
```

Result

description varchar	"first"("value") int64
value is even	2
value is uneven	1

`first_value`

Signature

```
first_value(self: _duckdb.DuckDBPyRelation, expression: str, window_spec: str = '', projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Computes the first value within the group or partition

Parameters

- **column** : str

  The column name from which to retrieve the first value.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.first_value(column="value", window_spec="over (partition by description order by value)", projected_columns="description").distinct()
```

Result

description varchar	first_value("value") OVER (PARTITION BY description ORDER BY "value") int64
value is even	2
value is uneven	1

`fsum`

Signature

```
fsum(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', window_spec: str = '',
projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Computes the sum of all values present in a given expression using a more accurate floating point summation (Kahan Sum)

Parameters

- **column** : str

  The column name to calculate the sum on.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.fsum(column="value", groups="description", projected_columns="description")
```

Result

description varchar	fsum("value") double
value is even	20.0
value is uneven	25.0

---

geomean

Signature

```
geomean(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', projected_columns: str = '')
-> _duckdb.DuckDBPyRelation
```

Description Computes the geometric mean over all values present in a given expression

Parameters

- **column** : str

  The column name to calculate the geometric mean on.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.geomean(column="value", groups="description", projected_columns="description")
```

Result

description varchar	geomean("value") double
value is uneven	3.936283427035351
value is even	4.426727678801287

`histogram`

Signature

```
histogram(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', window_spec: str = '',
projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Computes the histogram over all values present in a given expression

Parameters

- **column** : str

  The column name to calculate the histogram on.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.histogram(column="value", groups="description", projected_columns="description")
```

Result

description varchar	histogram("value") map(bigint, ubigint)
value is uneven	{1=1, 3=1, 5=1, 7=1, 9=1}
value is even	{2=1, 4=1, 6=1, 8=1}

`lag`

Signature

```
lag(self: _duckdb.DuckDBPyRelation, expression: str, window_spec: str, offset: typing.SupportsInt = 1,
default_value: str = 'NULL', ignore_nulls: bool = False, projected_columns: str = '') -> _
duckdb.DuckDBPyRelation
```

Description Computes the lag within the partition

Parameters

- **column** : str

  The column name to apply the lag function on.

- **window_spec** : str

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **offset** : int, default: 1

  The number of rows to lag behind.

- **default_value** : str, default: 'NULL'

  The default value to return when the lag offset goes out of bounds.

- **ignore_nulls** : bool, default: False

  Whether to ignore NULL values when computing the lag.

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
```

```
    """
)

rel.lag(column="description", window_spec="over (order by value)", projected_columns="description,
value")
```

Result

description varchar	value int64	lag(description, 1, NULL) OVER (ORDER BY "value") varchar
value is uneven	1	NULL
value is even	2	value is uneven
value is uneven	3	value is even
value is even	4	value is uneven
value is uneven	5	value is even
value is even	6	value is uneven
value is uneven	7	value is even
value is even	8	value is uneven
value is uneven	9	value is even

`last`

Signature

```
last(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', projected_columns: str = '') ->
_duckdb.DuckDBPyRelation
```

Description Returns the last value of a given expression

Parameters

- **column** : str

  The column name from which to retrieve the last value.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
```

```
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.last(column="value", groups="description", projected_columns="description")
```

Result

description varchar	"last"("value") int64
value is even	8
value is uneven	9

`last_value`

Signature

```
last_value(self: _duckdb.DuckDBPyRelation, expression: str, window_spec: str = '', projected_columns:
str = '') -> _duckdb.DuckDBPyRelation
```

Description Computes the last value within the group or partition

Parameters

- **column** : str

  The column name from which to retrieve the last value within the window.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)
```

```
rel.last_value(column="value", window_spec="over (order by description)", projected_
columns="description").distinct()
```

Result

description varchar	last_value("value") OVER (ORDER BY description) int64
value is uneven	9
value is even	8

`lead`

Signature

```
lead(self: _duckdb.DuckDBPyRelation, expression: str, window_spec: str, offset: typing.SupportsInt = 1,
default_value: str = 'NULL', ignore_nulls: bool = False, projected_columns: str = '') -> _
duckdb.DuckDBPyRelation
```

Description Computes the lead within the partition

Parameters

- **column** : str

  The column name to apply the lead function on.

- **window_spec** : str

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **offset** : int, default: 1

  The number of rows to lead ahead.

- **default_value** : str, default: 'NULL'

  The default value to return when the lead offset goes out of bounds.

- **ignore_nulls** : bool, default: False

  Whether to ignore NULL values when computing the lead.

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
```

```
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.lead(column="description", window_spec="over (order by value)", projected_columns="description,
value")
```

Result

description varchar	value int64	lead(description, 1, NULL) OVER (ORDER BY "value") varchar
value is uneven	1	value is even
value is even	2	value is uneven
value is uneven	3	value is even
value is even	4	value is uneven
value is uneven	5	value is even
value is even	6	value is uneven
value is uneven	7	value is even
value is even	8	value is uneven
value is uneven	9	NULL

`list`

Signature

```
list(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', window_spec: str = '',
projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Returns a list containing all values present in a given expression

Parameters

- **column** : str

  The column name to aggregate values into a list.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.list(column="value", groups="description", projected_columns="description")
```

Result

description varchar	list("value") int64[]
value is even	[2, 4, 6, 8]
value is uneven	[1, 3, 5, 7, 9]

---

max

Signature

```
max(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', window_spec: str = '', projected_
columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Returns the maximum value present in a given expression

Parameters

- **column** : str

  The column name to calculate the maximum value of.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

 rel.max(column="value", groups="description", projected_columns="description")
```

Result

description varchar	max("value") int64
value is even	8
value is uneven	9

---

mean

Signature

```
mean(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', window_spec: str = '',
projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Computes the average of a given expression

Parameters

- **column** : str

  The column name to calculate the mean value of.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.mean(column="value", groups="description", projected_columns="description")
```

Result

description varchar	avg("value") double
value is even	5.0
value is uneven	5.0

---

median

Signature

```
median(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', window_spec: str = '',
projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Computes the median over all values present in a given expression

Parameters

- **column** : str

  The column name to calculate the median value of.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.median(column="value", groups="description", projected_columns="description")
```

Result

description varchar	median("value") double
value is even	5.0
value is uneven	5.0

`min`

Signature

```
min(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', window_spec: str = '', projected_
columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Returns the minimum value present in a given expression

Parameters

- **column** : str

  The column name to calculate the min value of.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.min(column="value", groups="description", projected_columns="description")
```

Result

description varchar	min("value") int64
value is uneven	1
value is even	2

---

mode

Signature

```
mode(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', window_spec: str = '',
projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Computes the mode over all values present in a given expression

Parameters

- **column** : str

  The column name to calculate the mode (most frequent value) of.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.mode(column="value", groups="description", projected_columns="description")
```

Result

description varchar	"mode"("value") int64
value is uneven	1
value is even	2

---

n_tile

Signature

```
n_tile(self: _duckdb.DuckDBPyRelation, window_spec: str, num_buckets: typing.SupportsInt, projected_
columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Divides the partition as equally as possible into num_buckets

Parameters

- **window_spec** : str

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **num_buckets** : int

  The number of buckets to divide the rows into.

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.n_tile(window_spec="over (partition by description)", num_buckets=2, projected_columns="description,
value")
```

Result

description varchar	value int64	ntile(2) OVER (PARTITION BY description) int64
value is uneven	1	1
value is uneven	3	1
value is uneven	5	1
value is uneven	7	2
value is uneven	9	2
value is even	2	1
value is even	4	1
value is even	6	2
value is even	8	2

---

nth_value

Signature

```
nth_value(self: _duckdb.DuckDBPyRelation, expression: str, window_spec: str, offset: typing.SupportsInt,
ignore_nulls: bool = False, projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Computes the nth value within the partition

Parameters

- **column** : str

  The column name from which to retrieve the nth value within the window.

- **window_spec** : str

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **offset** : int

  The position of the value to retrieve within the window (1-based index).

- **ignore_nulls** : bool, default: False

  Whether to ignore NULL values when computing the nth value.

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.nth_value(column="value", window_spec="over (partition by description)", projected_
columns="description", offset=1)
```

Result

value is uneven	1
value is uneven	1

`percent_rank`

Signature

```
percent_rank(self: _duckdb.DuckDBPyRelation, window_spec: str, projected_columns: str = '') -> _
duckdb.DuckDBPyRelation
```

Description Computes the relative rank within the partition

Parameters

- **window_spec** : str

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.percent_rank(window_spec="over (partition by description order by value)", projected_
columns="description, value")
```

Result

description varchar	value int64	percent_rank() OVER (PARTITION BY description ORDER BY "value") double

value is uneven	5	0.5
value is uneven	7	0.75
value is uneven	9	1.0

---

product

Signature

```
product(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', window_spec: str = '',
projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Returns the product of all values present in a given expression

Parameters

- **column** : str

  The column name to calculate the product of.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.product(column="value", groups="description", projected_columns="description")
```

Result

description varchar	product("value") double
value is uneven	945.0
value is even	384.0

---

quantile

Signature

```
quantile(self: _duckdb.DuckDBPyRelation, expression: str, q: object = 0.5, groups: str = '', window_
spec: str = '', projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Computes the exact quantile value for a given expression

Parameters

- **column** : str

  The column name to compute the quantile for.

- **q** : object, default: 0.5

  The quantile value to compute (e.g., 0.5 for median).

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.quantile(column="value", groups="description", projected_columns="description")

value is even	4

---

quantile_cont

Signature

```
quantile_cont(self: _duckdb.DuckDBPyRelation, expression: str, q: object = 0.5, groups: str = '',
window_spec: str = '', projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Computes the interpolated quantile value for a given expression

Parameters

- **column** : str

  The column name to compute the continuous quantile for.

- **q** : object, default: 0.5

  The quantile value to compute (e.g., 0.5 for median).

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.quantile_cont(column="value", groups="description", projected_columns="description")
```

Result

description varchar	quantile_cont("value", 0.500000) double
value is even	5.0
value is uneven	5.0

---

quantile_disc

Signature

```
quantile_disc(self: _duckdb.DuckDBPyRelation, expression: str, q: object = 0.5, groups: str = '',
window_spec: str = '', projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Computes the exact quantile value for a given expression

Parameters

- **column** : str

  The column name to compute the discrete quantile for.

- **q** : object, default: 0.5

  The quantile value to compute (e.g., 0.5 for median).

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.quantile_disc(column="value", groups="description", projected_columns="description")
```

Result

description varchar	quantile_disc("value", 0.500000) int64
value is even	4
value is uneven	5

---

rank

Signature

```
rank(self: _duckdb.DuckDBPyRelation, window_spec: str, projected_columns: str = '') -> _
duckdb.DuckDBPyRelation
```

Description Computes the rank within the partition

Parameters

- **window_spec** : str

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.rank(window_spec="over (partition by description order by value)", projected_columns="description,
value")
```

Result

description varchar	value int64	rank() OVER (PARTITION BY description ORDER BY "value") int64
value is uneven	1	1
value is uneven	3	2
value is uneven	5	3
value is uneven	7	4
value is uneven	9	5
value is even	2	1
value is even	4	2
value is even	6	3
value is even	8	4

`rank_dense`

Signature

```
rank_dense(self: _duckdb.DuckDBPyRelation, window_spec: str, projected_columns: str = '') -> _
duckdb.DuckDBPyRelation
```

Description Computes the dense rank within the partition

Aliases: `dense_rank`

Parameters

- **window_spec** : str

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

 rel.rank_dense(window_spec="over (partition by description order by value)", projected_
columns="description, value")
```

Result

description varchar	value int64	dense_rank() OVER (PARTITION BY description ORDER BY "value") int64
value is uneven	1	1
value is uneven	3	2
value is uneven	5	3
value is uneven	7	4
value is uneven	9	5
value is even	2	1
value is even	4	2
value is even	6	3
value is even	8	4

---

row_number

Signature

```
row_number(self: _duckdb.DuckDBPyRelation, window_spec: str, projected_columns: str = '') -> _
duckdb.DuckDBPyRelation
```

Description Computes the row number within the partition

Parameters

- **window_spec** : str

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.row_number(window_spec="over (partition by description order by value)", projected_
columns="description, value")
```

Result

description varchar	value int64	row_number() OVER (PARTITION BY description ORDER BY "value") int64
value is uneven	1	1
value is uneven	3	2
value is uneven	5	3
value is uneven	7	4
value is uneven	9	5
value is even	2	1
value is even	4	2
value is even	6	3
value is even	8	4

`select_dtypes`

Signature

```
select_dtypes(self: _duckdb.DuckDBPyRelation, types: object) -> _duckdb.DuckDBPyRelation
```

Description Select columns from the relation, by filtering based on type(s)

Aliases: `select_types`

Parameters

- **types** : object

  Data type(s) to select columns by. Can be a single type or a collection of types.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.select_dtypes(types=[duckdb.sqltypes.VARCHAR]).distinct()
```

Result

```
┌──────────────────┐
│   description    │
│     varchar      │
├──────────────────┤
│ value is even    │
│ value is uneven  │
└──────────────────┘
```

`select_types`

Signature

```
select_types(self: _duckdb.DuckDBPyRelation, types: object) -> _duckdb.DuckDBPyRelation
```

Description Select columns from the relation, by filtering based on type(s)

Aliases: `select_dtypes`

Parameters

- **types** : object

  Data type(s) to select columns by. Can be a single type or a collection of types.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.select_types(types=[duckdb.sqltypes.VARCHAR]).distinct()
```

Result

description
varchar
value is even
value is uneven

---

std

Signature

```
std(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', window_spec: str = '', projected_
columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Computes the sample standard deviation for a given expression

Aliases: `stddev`, `stddev_samp`

Parameters

- **column** : str

  The column name to calculate the standard deviation for.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.std(column="value", groups="description", projected_columns="description")
```

Result

description varchar	stddev_samp("value") double
value is uneven value is even	3.1622776601683795 2.581988897471611

---

stddev

Signature

```
stddev(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', window_spec: str = '',
projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Computes the sample standard deviation for a given expression

Aliases: `std`, `stddev_samp`

Parameters

- **column** : str

  The column name to calculate the standard deviation for.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.stddev(column="value", groups="description", projected_columns="description")
```

stddev_pop

Signature

```
stddev_pop(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', window_spec: str = '',
projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Computes the population standard deviation for a given expression

Parameters

- **column** : str

  The column name to calculate the standard deviation for.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.stddev_pop(column="value", groups="description", projected_columns="description")
```

Result

value is uneven	2.8284271247461903

`stddev_samp`

Signature

```
stddev_samp(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', window_spec: str = '',
projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Computes the sample standard deviation for a given expression

Aliases: `stddev`, `std`

Parameters

- **column** : str

  The column name to calculate the standard deviation for.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.stddev_samp(column="value", groups="description", projected_columns="description")
```

Result

description varchar	stddev_samp("value") double

string_agg

Signature

```
string_agg(self: _duckdb.DuckDBPyRelation, expression: str, sep: str = ',', groups: str = '', window_
spec: str = '', projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Concatenates the values present in a given expression with a separator

Parameters

- **column** : str

  The column name to concatenate values from.

- **sep** : str, default: ','

  Separator string to use between concatenated values.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.string_agg(column="value", sep=",", groups="description", projected_columns="description")
```

Result

description varchar	string_agg("value", ',') varchar
value is even	2,4,6,8
value is uneven	1,3,5,7,9

---

sum

Signature

```
sum(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', window_spec: str = '', projected_
columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Computes the sum of all values present in a given expression

Parameters

- **column** : str

  The column name to calculate the sum for.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.sum(column="value", groups="description", projected_columns="description")
```

Result

description varchar	sum("value") int128
value is even	20
value is uneven	25

---

unique

Signature

```
unique(self: _duckdb.DuckDBPyRelation, unique_aggr: str) -> _duckdb.DuckDBPyRelation
```

Description Returns the distinct values in a column.

Parameters

- **unique_aggr** : str

  The column to get the distinct values for.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
```

```
    """
)

rel.unique(unique_aggr="description")
```

Result

```
┌─────────────────┐
│   description   │
│     varchar     │
├─────────────────┤
│ value is even   │
│ value is uneven │
└─────────────────┘
```

---

value_counts

Signature

```
value_counts(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '') -> _
duckdb.DuckDBPyRelation
```

Description Computes the number of elements present in a given expression, also projecting the original expression

Parameters

- **column** : str

  The column name to count values from.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.value_counts(column="description", groups="description")
```

Result

description varchar	count(description) int64
value is uneven	5
value is even	4

---

var

Signature

```
var(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', window_spec: str = '', projected_
columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Computes the sample variance for a given expression

Aliases: `variance`, `var_samp`

Parameters

- **column** : str

  The column name to calculate the sample variance for.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.var(column="value", groups="description", projected_columns="description")
```

Result

value is even	6.666666666666667
value is uneven	10.0

---

var_pop

Signature

```
var_pop(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', window_spec: str = '',
projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Computes the population variance for a given expression

Parameters

- **column** : str

  The column name to calculate the population variance for.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.var_pop(column="value", groups="description", projected_columns="description")
```

Result

description varchar	var_pop("value") double

Signature

```
var_samp(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', window_spec: str = '',
projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Computes the sample variance for a given expression

Aliases: `variance`, `var`

Parameters

- **column** : str

  The column name to calculate the sample variance for.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,

value is uneven	10.0

`variance`

Signature

```
variance(self: _duckdb.DuckDBPyRelation, expression: str, groups: str = '', window_spec: str = '',
projected_columns: str = '') -> _duckdb.DuckDBPyRelation
```

Description Computes the sample variance for a given expression

Aliases: `var`, `var_samp`

Parameters

- **column** : str

  The column name to calculate the sample variance for.

- **groups** : str, default: ''

  Comma-separated list of columns to include in the `group by`.

- **window_spec** : str, default: ''

  Optional window specification for window functions, provided as `over (partition by ... order by ...)`

- **projected_columns** : str, default: ''

  Comma-separated list of columns to include in the result.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.variance(column="value", groups="description", projected_columns="description")
```

Result

description varchar	var_samp("value") double
value is even	6.666666666666667
value is uneven	10.0

Output

This section contains the functions which will trigger an SQL execution and retrieve the data.

Name	Description
arrow	Alias of to_arrow_reader(). We recommend using to_arrow_reader() instead.
close	Closes the result
create	Creates a new table named table_name with the contents of the relation object
create_view	Creates a view named view_name that refers to the relation object
df	Execute and fetch all rows as a pandas DataFrame
execute	Transform the relation into a result set
fetch_arrow_reader	Execute and return an Arrow Record Batch Reader that yields all rows
fetch_arrow_table	Execute and fetch all rows as an Arrow Table
fetch_df_chunk	Execute and fetch a chunk of the rows
fetch_record_batch	Execute and return an Arrow Record Batch Reader that yields all rows
fetchall	Execute and fetch all rows as a list of tuples
fetchdf	Execute and fetch all rows as a pandas DataFrame
fetchmany	Execute and fetch the next set of rows as a list of tuples
fetchnumpy	Execute and fetch all rows as a Python dict mapping each column to one numpy arrays
fetchone	Execute and fetch a single row as a tuple
pl	Execute and fetch all rows as a Polars DataFrame
tf	Fetch a result as dict of TensorFlow Tensors
to_arrow_reader	Execute and return an Arrow Record Batch Reader that yields all rows
to_arrow_table	Execute and fetch all rows as an Arrow Table
to_csv	Write the relation object to a CSV file in 'file_name'
to_df	Execute and fetch all rows as a pandas DataFrame
to_parquet	Write the relation object to a Parquet file in 'file_name'
to_table	Creates a new table named table_name with the contents of the relation object
to_view	Creates a view named view_name that refers to the relation object
torch	Fetch a result as dict of PyTorch Tensors
write_csv	Write the relation object to a CSV file in 'file_name'
write_parquet	Write the relation object to a Parquet file in 'file_name'

arrow

Signature

```
arrow(self: _duckdb.DuckDBPyRelation, batch_size: typing.SupportsInt = 1000000) ->
pyarrow.lib.RecordBatchReader
```

Description Alias of to_arrow_reader(). We recommend using to_arrow_reader() instead.

> We recommend using `to_arrow_reader()` instead.

Aliases: `to_arrow_reader`

Parameters

- **batch_size** : int, default: 1000000

  The batch size for fetching the data.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

pa_reader = rel.arrow(batch_size=1)

pa_reader.read_next_batch()
```

Result

```
pyarrow.RecordBatch
id: string
description: string
value: int64
created_timestamp: timestamp[us, tz=Europe/Amsterdam]
----
id: ["e4ab8cb4-4609-40cb-ad7e-4304ed5ed4bd"]
description: ["value is even"]
value: [2]
created_timestamp: [2025-04-10 09:25:51.259000Z]
```

---

close

Signature

```
close(self: _duckdb.DuckDBPyRelation) -> None
```

Description Closes the result

`create`

Signature

```
create(self: _duckdb.DuckDBPyRelation, table_name: str) -> None
```

Description Creates a new table named table_name with the contents of the relation object

Aliases: `to_table`

Parameters

- **table_name** : str

  The name of the table to be created. There shouldn't be any other table with the same name.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.create("table_code_example")

duckdb_conn.table("table_code_example").limit(1)
```

Result

id uuid	description varchar	value int64	created_timestamp timestamp with time zone
3ac9e0ba-8390-4a02-ad72-33b1caea6354	value is uneven	1	2025-04-10 11:07:12.614+02

`create_view`

Signature

```
create_view(self: _duckdb.DuckDBPyRelation, view_name: str, replace: bool = True) -> _
duckdb.DuckDBPyRelation
```

Description Creates a view named view_name that refers to the relation object

Aliases: `to_view`

Parameters

- **view_name** : str

  The name of the view to be created.

- **replace** : bool, default: True

  If the view should be created with `CREATE OR REPLACE`. When set to `False`, there shouldn't be another view with the same `view_name`.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.create_view("view_code_example", replace=True)

duckdb_conn.table("view_code_example").limit(1)
```

Result

id uuid	description varchar	value int64	created_timestamp timestamp with time zone
3ac9e0ba-8390-4a02-ad72-33b1caea6354	value is uneven	1	2025-04-10 11:07:12.614+02

---

df

Signature

```
df(self: _duckdb.DuckDBPyRelation, *, date_as_object: bool = False) -> pandas.DataFrame
```

Description Execute and fetch all rows as a pandas DataFrame

Aliases: `fetchdf`, `to_df`

Parameters

- **date_as_object** : bool, default: False

  If the date columns should be interpreted as Python date objects.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.df()
```

Result

```
                                     id      description  value                created_timestamp
0  3ac9e0ba-8390-4a02-ad72-33b1caea6354  value is uneven      1 2025-04-10 11:07:12.614000+02:00
1  8b844392-1404-4bbc-b731-120f42c8ca27    value is even      2 2025-04-10 11:08:12.614000+02:00

...
```

---

execute

Signature

```
execute(self: _duckdb.DuckDBPyRelation) -> _duckdb.DuckDBPyRelation
```

Description Transform the relation into a result set

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
```

```
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.execute()
```

Result

id uuid	description varchar	value int64	created_timestamp timestamp with time zone
3ac9e0ba-8390-4a02-ad72-33b1caea6354	value is uneven	1	2025-04-10 11:07:12.614+02

`fetch_arrow_reader`

Signature

```
fetch_arrow_reader(self: object, batch_size: typing.SupportsInt = 1000000) -> object
```

Description Execute and return an Arrow Record Batch Reader that yields all rows

> **Deprecated.** `fetch_arrow_reader()` is deprecated. Use `to_arrow_reader()` instead.

Parameters

- **batch_size** : int, default: 1000000

  The batch size for fetching the data.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

pa_reader = rel.fetch_arrow_reader(batch_size=1)

pa_reader.read_next_batch()
```

Result

```
pyarrow.RecordBatch
id: string
description: string
value: int64
created_timestamp: timestamp[us, tz=Europe/Amsterdam]
----
id: ["e4ab8cb4-4609-40cb-ad7e-4304ed5ed4bd"]
description: ["value is even"]

```

`fetch_arrow_table`

Signature

```
fetch_arrow_table(self: object, batch_size: typing.SupportsInt = 1000000) -> object
```

Description Execute and fetch all rows as an Arrow Table

> **Deprecated.** `fetch_arrow_table()` is deprecated. Use `to_arrow_table()` instead.

Aliases: `arrow`, `to_arrow_table`

Parameters

- **batch_size** : int, default: 1000000

  The batch size for fetching the data.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.fetch_arrow_table()
```

Result

```
pyarrow.Table
id: string
description: string
value: int64
```

```

`fetch_df_chunk`

Signature

```
fetch_df_chunk(self: _duckdb.DuckDBPyRelation, vectors_per_chunk: typing.SupportsInt = 1, *, date_as_
object: bool = False) -> pandas.DataFrame
```

Description Execute and fetch a chunk of the rows

Parameters

- **vectors_per_chunk** : int, default: 1

  Number of data chunks to be processed before converting to dataframe.

- **date_as_object** : bool, default: False

  If the date columns should be interpreted as Python date objects.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.fetch_df_chunk()
```

Result

```
                                     id      description  value                created_timestamp
0  1587b4b0-3023-49fe-82cf-06303ca136ac  value is uneven      1 2025-04-10 11:24:51.259000+02:00

...
```

`fetch_record_batch`

Signature

```
fetch_record_batch(self: object, rows_per_batch: typing.SupportsInt = 1000000) -> object
```

Description Execute and return an Arrow Record Batch Reader that yields all rows

> **Deprecated.** `fetch_record_batch()` is deprecated. Use `to_arrow_reader()` instead.

Aliases: `record_batch`

Parameters

- **rows_per_batch** : int, default: 1000000

  The number of rows per batch.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

pa_reader = rel.fetch_record_batch(rows_per_batch=1)

pa_reader.read_next_batch()
```

Result

```
pyarrow.RecordBatch
id: string
description: string
value: int64
created_timestamp: timestamp[us, tz=Europe/Amsterdam]
----
id: ["908cf67c-a086-4b94-9017-2089a83e4a6c"]
description: ["value is uneven"]
value: [1]
created_timestamp: [2025-04-10 09:52:55.249000Z]
```

`fetchall`

Signature

```
fetchall(self: _duckdb.DuckDBPyRelation) -> list
```

Description Execute and fetch all rows as a list of tuples

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.limit(1).fetchall()
```

Result

```
[(UUID('1587b4b0-3023-49fe-82cf-06303ca136ac'),
  'value is uneven',
  1,
  datetime.datetime(2025, 4, 10, 11, 24, 51, 259000, tzinfo=<DstTzInfo 'Europe/Amsterdam' CEST+2:00:00
DST>))]
```

`fetchdf`

Signature

```
fetchdf(self: _duckdb.DuckDBPyRelation, *, date_as_object: bool = False) -> pandas.DataFrame
```

Description Execute and fetch all rows as a pandas DataFrame

Aliases: `df`, `to_df`

Parameters

- **date_as_object** : bool, default: False

  If the date columns should be interpreted as Python date objects.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.fetchdf()
```

Result

```
                                     id      description  value                created_timestamp
0  1587b4b0-3023-49fe-82cf-06303ca136ac  value is uneven      1 2025-04-10 11:24:51.259000+02:00
1  e4ab8cb4-4609-40cb-ad7e-4304ed5ed4bd    value is even      2 2025-04-10 11:25:51.259000+02:00
2  3f8ad67a-290f-4a22-b41b-0173b8e45afa  value is uneven      3 2025-04-10 11:26:51.259000+02:00
...
```

`fetchmany`

Signature

```
fetchmany(self: _duckdb.DuckDBPyRelation, size: typing.SupportsInt = 1) -> list
```

Description Execute and fetch the next set of rows as a list of tuples

> Warning Executing any operation during the retrieval of the data from an aggregate relation, will close the result set.
>
> ```
> import duckdb
>
> duckdb_conn = duckdb.connect()
>
> rel = duckdb_conn.sql("""
>       select
>           gen_random_uuid() as id,
>          concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
>           range as value,
>           now() + concat(range,' ', 'minutes')::interval as created_timestamp
>       from range(1, 10)
>    """
> )
>
> agg_rel = rel.aggregate("value")
>
> while res := agg_rel.fetchmany(size=1):
>    print(res)
>    rel.show()
> ```

Parameters

- **size** : int, default: 1

  The number of records to be fetched.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

while res := rel.fetchmany(size=1):
    print(res)
```

Result

```

```

`fetchnumpy`

Signature

```
fetchnumpy(self: _duckdb.DuckDBPyRelation) -> dict
```

Description Execute and fetch all rows as a Python dict mapping each column to one numpy arrays

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.fetchnumpy()
```

Result

```
{'id': array([UUID('1587b4b0-3023-49fe-82cf-06303ca136ac'),

```

---

pl

Signature

```
pl(self: _duckdb.DuckDBPyRelation, batch_size: typing.SupportsInt = 1000000, *, lazy: bool = False) ->
duckdb::PolarsDataFrame
```

Description Execute and fetch all rows as a Polars DataFrame

Parameters

- **batch_size** : int, default: 1000000

  The number of records to be fetched per batch.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,

to_arrow_reader

Signature

```
to_arrow_reader(self: _duckdb.DuckDBPyRelation, batch_size: typing.SupportsInt = 1000000) ->
pyarrow.lib.RecordBatchReader
```

Description Execute and return an Arrow Record Batch Reader that yields all rows

Aliases: `arrow`

Parameters

- **batch_size** : int, default: 1000000

  The batch size for fetching the data.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
```

```
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

pa_reader = rel.to_arrow_reader(batch_size=1)

pa_reader.read_next_batch()
```

Result

```
pyarrow.RecordBatch

```

---

to_arrow_table

Signature

```
to_arrow_table(self: _duckdb.DuckDBPyRelation, batch_size: typing.SupportsInt = 1000000) ->
pyarrow.lib.Table
```

Description Execute and fetch all rows as an Arrow Table

Aliases: `fetch_arrow_table`

Parameters

- **batch_size** : int, default: 1000000

  The batch size for fetching the data.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

```

`to_csv`

Signature

```
to_csv(self: _duckdb.DuckDBPyRelation, file_name: str, *, sep: object = None, na_rep: object = None,
header: object = None, quotechar: object = None, escapechar: object = None, date_format: object = None,
timestamp_format: object = None, quoting: object = None, encoding: object = None, compression: object =
None, overwrite: object = None, per_thread_output: object = None, use_tmp_file: object = None,
partition_by: object = None, write_partition_columns: object = None) -> None
```

Description Write the relation object to a CSV file in 'file_name'

Aliases: `write_csv`

Parameters

- **file_name** : str

  The name of the output CSV file.

- **sep** : str, default: ','

  Field delimiter for the output file.

- **na_rep** : str, default: ''

  Missing data representation.

- **header** : bool, default: True

  Whether to write column headers.

- **quotechar** : str, default: '"'

  Character used to quote fields containing special characters.

- **escapechar** : str, default: None

  Character used to escape the delimiter if quoting is set to QUOTE_NONE.

- **date_format** : str, default: None

  Custom format string for DATE values.

- **timestamp_format** : str, default: None

  Custom format string for TIMESTAMP values.

- **quoting** : int, default: csv.QUOTE_MINIMAL

  Control field quoting behavior (e.g., QUOTE_MINIMAL, QUOTE_ALL).

- **encoding** : str, default: 'utf-8'

  Character encoding for the output file.

- **compression** : str, default: auto

  Compression type (e.g., 'gzip', 'bz2', 'zstd').

- **overwrite** : bool, default: False

  When true, all existing files inside targeted directories will be removed (not supported on remote filesystems). Only has an effect when used with `partition_by`.

- **per_thread_output** : bool, default: False

  When `true`, write one file per thread, rather than one file in total. This allows for faster parallel writing.

- **use_tmp_file** : bool, default: False

  Write to a temporary file before renaming to final name to avoid partial writes.

- **partition_by** : list[str], default: None

  List of column names to partition output by (creates folder structure).

- **write_partition_columns** : bool, default: False

  Whether or not to write partition columns into files. Only has an effect when used with `partition_by`.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.to_csv("code_example.csv")
```

Result

```
The data is exported to a CSV file, named code_example.csv
```

---

to_df

Signature

```
to_df(self: _duckdb.DuckDBPyRelation, *, date_as_object: bool = False) -> pandas.DataFrame
```

Description Execute and fetch all rows as a pandas DataFrame

Aliases: `fetchdf`, `df`

Parameters

- **date_as_object** : bool, default: False

  If the date columns should be interpreted as Python date objects.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.to_df()
```

Result

```
                                     id      description  value                created_timestamp
0  e1f79925-60fd-4ee2-ae67-5eff6b0543d1  value is uneven      1 2025-04-10 11:56:04.452000+02:00

2  64c68032-99b9-4e8f-b4a3-6c522d5419b3  value is uneven      3 2025-04-10 11:58:04.452000+02:00
...
```

---

to_parquet

Signature

```
to_parquet(self: _duckdb.DuckDBPyRelation, file_name: str, *, compression: object = None, field_ids:
object = None, row_group_size_bytes: object = None, row_group_size: object = None, overwrite: object =
None, per_thread_output: object = None, use_tmp_file: object = None, partition_by: object = None, write_
partition_columns: object = None, append: object = None, filename_pattern: object = None, file_size_
bytes: object = None) -> None
```

Description Write the relation object to a Parquet file in 'file_name'

Aliases: `write_parquet`

Parameters

- **file_name** : str

  The name of the output Parquet file.

- **compression** : str, default: 'snappy'

  The compression format to use (`uncompressed`, `snappy`, `gzip`, `zstd`, `brotli`, `lz4`, `lz4_raw`).

- **field_ids** : STRUCT

  The field_id for each column. Pass auto to attempt to infer automatically.

- **row_group_size_bytes** : int, default: row_group_size * 1024

  The target size of each row group. You can pass either a human-readable string, e.g., 2MB, or an integer, i.e., the number of bytes. This option is only used when you have issued `SET preserve_insertion_order = false;`, otherwise, it is ignored.

- **row_group_size** : int, default: 122880

  The target size, i.e., number of rows, of each row group.

- **overwrite** : bool, default: False

  If True, overwrite the file if it exists.

- **per_thread_output** : bool, default: False

  When `True`, write one file per thread, rather than one file in total. This allows for faster parallel writing.

- **use_tmp_file** : bool, default: False

  Write to a temporary file before renaming to final name to avoid partial writes.

- **partition_by** : list[str], default: None

  List of column names to partition output by (creates folder structure).

- **write_partition_columns** : bool, default: False

  Whether or not to write partition columns into files. Only has an effect when used with `partition_by`.

- **append** : bool, default: False

  When `True`, in the event a filename pattern is generated that already exists, the path will be regenerated to ensure no existing files are overwritten. Only has an effect when used with `partition_by`.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.to_parquet("code_example.parquet")
```

Result

```
The data is exported to a Parquet file, named code_example.parquet
```

---

to_table

Signature

```
to_table(self: _duckdb.DuckDBPyRelation, table_name: str) -> None
```

Description Creates a new table named table_name with the contents of the relation object

Aliases: `create`

Parameters

- **table_name** : str

  The name of the table to be created. There shouldn't be any other table with the same name.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.to_table("table_code_example")
```

Result

```
A table, named table_code_example, is created with the data of the relation
```

---

to_view

Signature

```
to_view(self: _duckdb.DuckDBPyRelation, view_name: str, replace: bool = True) -> _duckdb.DuckDBPyRelation
```

Description Creates a view named view_name that refers to the relation object

Aliases: `create_view`

Parameters

- **view_name** : str

  The name of the view to be created.

- **replace** : bool, default: True

  If the view should be created with `CREATE OR REPLACE`. When set to `False`, there shouldn't be another view with the same `view_name`.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.to_view("view_code_example", replace=True)
```

Result

```
A view, named view_code_example, is created with the query definition of the relation
```

`torch`

Signature

```
torch(self: _duckdb.DuckDBPyRelation) -> dict
```

Description Fetch a result as dict of PyTorch Tensors

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)
```

```
rel.select("value").torch()
```

Result

```
{'value': tensor([1, 2, 3, 4, 5, 6, 7, 8, 9])}
```

---

write_csv

Signature

```
write_csv(self: _duckdb.DuckDBPyRelation, file_name: str, *, sep: object = None, na_rep: object = None,
header: object = None, quotechar: object = None, escapechar: object = None, date_format: object = None,
timestamp_format: object = None, quoting: object = None, encoding: object = None, compression: object =
None, overwrite: object = None, per_thread_output: object = None, use_tmp_file: object = None,
partition_by: object = None, write_partition_columns: object = None) -> None
```

Description Write the relation object to a CSV file in 'file_name'

Aliases: `to_csv`

Parameters

- **file_name** : str

  The name of the output CSV file.

- **sep** : str, default: ','

  Field delimiter for the output file.

- **na_rep** : str, default: ''

  Missing data representation.

- **header** : bool, default: True

  Whether to write column headers.

- **quotechar** : str, default: '"'

  Character used to quote fields containing special characters.

- **escapechar** : str, default: None

  Character used to escape the delimiter if quoting is set to QUOTE_NONE.

- **date_format** : str, default: None

  Custom format string for DATE values.

- **timestamp_format** : str, default: None

  Custom format string for TIMESTAMP values.

- **quoting** : int, default: csv.QUOTE_MINIMAL

  Control field quoting behavior (e.g., QUOTE_MINIMAL, QUOTE_ALL).

- **encoding** : str, default: 'utf-8'

  Character encoding for the output file.

- **compression** : str, default: auto

  Compression type (e.g., 'gzip', 'bz2', 'zstd').

- **overwrite** : bool, default: False

  When true, all existing files inside targeted directories will be removed (not supported on remote filesystems). Only has an effect when used with `partition_by`.

- **per_thread_output** : bool, default: False

  When `true`, write one file per thread, rather than one file in total. This allows for faster parallel writing.

- **use_tmp_file** : bool, default: False

  Write to a temporary file before renaming to final name to avoid partial writes.

- **partition_by** : list[str], default: None

  List of column names to partition output by (creates folder structure).

- **write_partition_columns** : bool, default: False

  Whether or not to write partition columns into files. Only has an effect when used with `partition_by`.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.write_csv("code_example.csv")
```

Result

```
The data is exported to a CSV file, named code_example.csv
```

`write_parquet`

Signature

```
write_parquet(self: _duckdb.DuckDBPyRelation, file_name: str, *, compression: object = None, field_ids:
object = None, row_group_size_bytes: object = None, row_group_size: object = None, overwrite: object =
None, per_thread_output: object = None, use_tmp_file: object = None, partition_by: object = None, write_
partition_columns: object = None, append: object = None, filename_pattern: object = None, file_size_
bytes: object = None) -> None
```

Description Write the relation object to a Parquet file in 'file_name'

Aliases: `to_parquet`

Parameters

- **file_name** : str

  The name of the output Parquet file.

- **compression** : str, default: 'snappy'

  The compression format to use (`uncompressed`, `snappy`, `gzip`, `zstd`, `brotli`, `lz4`, `lz4_raw`).

- **field_ids** : STRUCT

  The field_id for each column. Pass auto to attempt to infer automatically.

- **row_group_size_bytes** : int, default: row_group_size * 1024

  The target size of each row group. You can pass either a human-readable string, e.g., 2MB, or an integer, i.e., the number of bytes. This option is only used when you have issued `SET preserve_insertion_order = false;`, otherwise, it is ignored.

- **row_group_size** : int, default: 122880

  The target size, i.e., number of rows, of each row group.

- **overwrite** : bool, default: False

  If True, overwrite the file if it exists.

- **per_thread_output** : bool, default: False

  When `True`, write one file per thread, rather than one file in total. This allows for faster parallel writing.

- **use_tmp_file** : bool, default: False

  Write to a temporary file before renaming to final name to avoid partial writes.

- **partition_by** : list[str], default: None

  List of column names to partition output by (creates folder structure).

- **write_partition_columns** : bool, default: False

  Whether or not to write partition columns into files. Only has an effect when used with `partition_by`.

- **append** : bool, default: False

  When `True`, in the event a filename pattern is generated that already exists, the path will be regenerated to ensure no existing files are overwritten. Only has an effect when used with `partition_by`.

Example

```
import duckdb

duckdb_conn = duckdb.connect()

rel = duckdb_conn.sql("""
        select
            gen_random_uuid() as id,
            concat('value is ', case when mod(range,2)=0 then 'even' else 'uneven' end) as description,
            range as value,
            now() + concat(range,' ', 'minutes')::interval as created_timestamp
        from range(1, 10)
    """
)

rel.write_parquet("code_example.parquet")
```

Result

```
The data is exported to a Parquet file, named code_example.parquet
```

Python Function API

You can create a DuckDB user-defined function (UDF) from a Python function so it can be used in SQL queries. Similarly to regular functions, they need to have a name, a return type and parameter types.

Here is an example using a Python function that calls a third-party library.

```
import duckdb
from duckdb.sqltypes import VARCHAR
from faker import Faker

def generate_random_name():
    fake = Faker()
    return fake.name()

duckdb.create_function("random_name", generate_random_name, [], VARCHAR)
res = duckdb.sql("SELECT random_name()").fetchall()
print(res)
```

```
[('Gerald Ashley',)]
```

Creating Functions

To register a Python UDF, use the `create_function` method from a DuckDB connection. Here is the syntax:

```
import duckdb
con = duckdb.connect()
con.create_function(name, function, parameters, return_type)
```

The `create_function` method takes the following parameters:

1. `name` A string representing the unique name of the UDF within the connection catalog.
2. `function` The Python function you wish to register as a UDF.
3. `parameters` Scalar functions can operate on one or more columns. This parameter takes a list of column types used as input.
4. `return_type` Scalar functions return one element per row. This parameter specifies the return type of the function.
5. `type` (optional): DuckDB supports both native Python types and PyArrow Arrays. By default, `type = 'native'` is assumed, but you can specify `type = 'arrow'` to use PyArrow Arrays. In general, using an Arrow UDF will be much more efficient than native because it will be able to operate in batches.
6. `null_handling` (optional): By default, `NULL` values are automatically handled as `NULL`-in `NULL`-out. Users can specify a desired behavior for `NULL` values by setting `null_handling = 'special'`.
7. `exception_handling` (optional): By default, when an exception is thrown from the Python function, it will be re-thrown in Python. Users can disable this behavior, and instead return `NULL`, by setting this parameter to `'return_null'`
8. `side_effects` (optional): By default, functions are expected to produce the same result for the same input. If the result of a function is impacted by any type of randomness, `side_effects` must be set to `True`.

To unregister a UDF, you can call the `remove_function` method with the UDF name:

```
con.remove_function(name)
```

Using Partial Functions

DuckDB UDFs can also be created with Python partial functions.

In the below example, we show how a custom logger will return the concatenation of the execution datetime in ISO format, always followed by argument passed at UDF creation and the input parameter provided to the function call:

```
from datetime import datetime
import duckdb
import functools

def get_datetime_iso_format() -> str:
    return datetime.now().isoformat()

def logger_udf(func, arg1: str, arg2: int) -> str:
    return ' '.join([func(), arg1, str(arg2)])

with duckdb.connect() as con:
    con.sql("select * from range(10) tbl(id)").to_table("example_table")

    con.create_function(
        'custom_logger',
        functools.partial(logger_udf, get_datetime_iso_format, 'logging data')
    )
    rel = con.sql("SELECT custom_logger(id) from example_table;")
    rel.show()

    con.create_function(
        'another_custom_logger',
        functools.partial(logger_udf, get_datetime_iso_format, ':')
    )
    rel = con.sql("SELECT another_custom_logger(id) from example_table;")
    rel.show()
```

```
┌──────────────────────────────────────────┐
│            custom_logger(id)            │
│                  varchar                 │
├──────────────────────────────────────────┤

├──────────────────────────────────┤
│            10 rows               │
└──────────────────────────────────┘
```

Type Annotation

When the function has type annotation it's often possible to leave out all of the optional parameters. Using `DuckDBPyType` we can implicitly convert many known types to DuckDB's type system. For example:

```
import duckdb

def my_function(x: int) -> str:
    return x

duckdb.create_function("my_func", my_function)
print(duckdb.sql("SELECT my_func(42)"))
```

```
┌─────────────┐
│ my_func(42) │
│   varchar   │
├─────────────┤
│ 42          │
└─────────────┘
```

If only the parameter list types can be inferred, you'll need to pass in None as `parameters`.

NULL Handling

By default when functions receive a `NULL` value, this instantly returns `NULL`, as part of the default `NULL`-handling. When this is not desired, you need to explicitly set this parameter to `"special"`.

```
import duckdb
from duckdb.sqltypes import BIGINT

def dont_intercept_null(x):
    return 5

duckdb.create_function("dont_intercept", dont_intercept_null, [BIGINT], BIGINT)
res = duckdb.sql("SELECT dont_intercept(NULL)").fetchall()
print(res)
```

```
[(None,)]
```

With `null_handling="special"`:

```
import duckdb
from duckdb.sqltypes import BIGINT

def dont_intercept_null(x):
    return 5

duckdb.create_function("dont_intercept", dont_intercept_null, [BIGINT], BIGINT, null_handling="special")
res = duckdb.sql("SELECT dont_intercept(NULL)").fetchall()
print(res)
```

```
[(5,)]
```

> Always use `null_handling="special"` when the function can return NULL.

```
import duckdb
from duckdb.sqltypes import VARCHAR

def return_str_or_none(x: str) -> str | None:
    if not x:
        return None

    return x

duckdb.create_function(
    "return_str_or_none",
    return_str_or_none,
    [VARCHAR],
    VARCHAR,
    null_handling="special"
)
res = duckdb.sql("SELECT return_str_or_none('')").fetchall()
print(res)
```

```
[(None,)]
```

Exception Handling

By default, when an exception is thrown from the Python function, we'll forward (re-throw) the exception. If you want to disable this behavior, and instead return NULL, you'll need to set this parameter to `"return_null"`.

```
import duckdb
from duckdb.sqltypes import BIGINT

def will_throw():
    raise ValueError("ERROR")

duckdb.create_function("throws", will_throw, [], BIGINT)
try:
    res = duckdb.sql("SELECT throws()").fetchall()
except duckdb.InvalidInputException as e:
    print(e)

duckdb.create_function("doesnt_throw", will_throw, [], BIGINT, exception_handling="return_null")
res = duckdb.sql("SELECT doesnt_throw()").fetchall()
print(res)
```

```
Invalid Input Error:
Python exception occurred while executing the UDF: ValueError: ERROR

At:
  ...(5): will_throw
  ...(9): <module>

[(None,)]
```

Side Effects

By default DuckDB will assume the created function is a *pure* function, meaning it will produce the same output when given the same input. If your function does not follow that rule, for example when your function makes use of randomness, then you will need to mark this function as having `side_effects`.

For example, this function will produce a new count for every invocation.

```
def count() -> int:
    old = count.counter;
    count.counter += 1
    return old

count.counter = 0
```

If we create this function without marking it as having side effects, the result will be the following:

```
con = duckdb.connect()
con.create_function("my_counter", count, side_effects=False)
res = con.sql("SELECT my_counter() FROM range(10)").fetchall()
print(res)
```

```
[(0,), (0,), (0,), (0,), (0,), (0,), (0,), (0,), (0,), (0,)]
```

Which is obviously not the desired result, when we add `side_effects=True`, the result is as we would expect:

```
con.remove_function("my_counter")
count.counter = 0
con.create_function("my_counter", count, side_effects=True)
res = con.sql("SELECT my_counter() FROM range(10)").fetchall()
print(res)
```

```
[(0,), (1,), (2,), (3,), (4,), (5,), (6,), (7,), (8,), (9,)]
```

Python Function Types

Currently, two function types are supported, `native` (default) and `arrow`.

Arrow

If the function is expected to receive arrow arrays, set the `type` parameter to `'arrow'`.

This will let the system know to provide arrow arrays of up to `STANDARD_VECTOR_SIZE` tuples to the function, and also expect an array of the same amount of tuples to be returned from the function.

In general, using an Arrow UDF will be much more efficient than native because it will be able to operate in batches.

```
import duckdb
import pyarrow as pa
from duckdb.sqltypes import VARCHAR
from pyarrow import compute as pc

def mirror(strings: pa.Array, sep: pa.Array) -> pa.Array:
    assert isinstance(strings, pa.ChunkedArray)
    assert isinstance(sep, pa.ChunkedArray)
    return pc.binary_join_element_wise(strings, pc.ascii_reverse(strings), sep)

duckdb.create_function(
```

```
    "mirror",
    mirror,
    [VARCHAR, VARCHAR],
    return_type=VARCHAR,
    type="arrow",
)

duckdb.sql(
    "CREATE OR REPLACE TABLE strings AS SELECT 'hello' AS str UNION ALL SELECT 'world' AS str;"
)
print(duckdb.sql("SELECT mirror(str, '|') FROM strings;").fetchall())
```

```
[('hello|olleh',), ('world|dlrow',)]
```

Native

When the function type is set to `native` the function will be provided with a single tuple at a time, and expect only a single value to be returned. This can be useful to interact with Python libraries that don't operate on Arrow, such as `faker`:

```
import duckdb

from duckdb.sqltypes import DATE
from faker import Faker

def random_date():
    fake = Faker()
    return fake.date_between()

duckdb.create_function(
    "random_date",
    random_date,
    parameters=[],
    return_type=DATE,
    type="native",
)
res = duckdb.sql("SELECT random_date()").fetchall()
print(res)
```

```
[(datetime.date(2019, 5, 15),)]
```

Types API

The `DuckDBPyType` class represents a type instance of our data types.

Converting from Other Types

To make the API as easy to use as possible, we have added implicit conversions from existing type objects to a DuckDBPyType instance. This means that wherever a DuckDBPyType object is expected, it is also possible to provide any of the options listed below.

Python Built-Ins

The table below shows the mapping of Python Built-in types to DuckDB type.

Built-in types	DuckDB type
bool	BOOLEAN
bytearray	BLOB
bytes	BLOB
float	DOUBLE
int	BIGINT
str	VARCHAR

Numpy DTypes

The table below shows the mapping of Numpy DType to DuckDB type.

Type	DuckDB type
bool	BOOLEAN
float32	FLOAT
float64	DOUBLE
int16	SMALLINT
int32	INTEGER
int64	BIGINT
int8	TINYINT
uint16	USMALLINT
uint32	UINTEGER
uint64	UBIGINT
uint8	UTINYINT

Nested Types

`list[child_type]` `list` type objects map to a `LIST` type of the child type. Which can also be arbitrarily nested.

```
import duckdb.sqltypes
from typing import Union

duckdb.sqltypes.DuckDBPyType(list[dict[Union[str, int], str]])
```

```
MAP(UNION(u1 VARCHAR, u2 BIGINT), VARCHAR)[]
```

`dict[key_type, value_type]` `dict` type objects map to a `MAP` type of the key type and the value type.

```
import duckdb.sqltypes

print(duckdb.sqltypes.DuckDBPyType(dict[str, int]))
```

```
MAP(VARCHAR, BIGINT)
```

`{'a': field_one, 'b': field_two, ..., 'n': field_n}` `dict` objects map to a STRUCT composed of the keys and values of the dict.

```
import duckdb.sqltypes

print(duckdb.sqltypes.DuckDBPyType({'a': str, 'b': int}))
```

```
STRUCT(a VARCHAR, b BIGINT)
```

`Union[type_1, ... type_n]` `typing.Union` objects map to a `UNION` type of the provided types.

```
import duckdb.sqltypes
from typing import Union

print(duckdb.sqltypes.DuckDBPyType(Union[int, str, bool, bytearray]))
```

```
UNION(u1 BIGINT, u2 VARCHAR, u3 BOOLEAN, u4 BLOB)
```

Creation Functions

For the built-in types, you can use the constants defined in `duckdb.sqltypes`:

DuckDB type
BIGINT
BIT
BLOB
BOOLEAN
DATE
DOUBLE
FLOAT
HUGEINT
INTEGER
INTERVAL
SMALLINT
SQLNULL
TIME_TZ
TIME
TIMESTAMP_MS
TIMESTAMP_NS
TIMESTAMP_S
TIMESTAMP_TZ
TIMESTAMP
TINYINT
UBIGINT
UHUGEINT
UINTEGER
USMALLINT

DuckDB type
UTINYINT
UUID
VARCHAR

For the complex types there are methods available on the `DuckDBPyConnection` object or the `duckdb` module. Anywhere a `DuckDBPyType` is accepted, we will also accept one of the type objects that can implicitly convert to a `DuckDBPyType`.

`list_type|array_type` Parameters:

- `child_type: DuckDBPyType`

`struct_type|row_type` Parameters:

- `fields: Union[list[DuckDBPyType], dict[str, DuckDBPyType]]`

`map_type` Parameters:

- `key_type: DuckDBPyType`
- `value_type: DuckDBPyType`

`decimal_type` Parameters:

- `width: int`
- `scale: int`

`union_type` Parameters:

- `members: Union[list[DuckDBPyType], dict[str, DuckDBPyType]]`

`string_type` Parameters:

- `collation: Optional[str]`

Expression API

The `Expression` class represents an instance of an expression.

Why Would I Use the Expression API?

Using this API makes it possible to dynamically build up expressions, which are typically created by the parser from the query string. This allows you to skip that and have more fine-grained control over the used expressions.

Below is a list of currently supported expressions that can be created through the API.

Column Expression

This expression references a column by name.

```
import duckdb
import pandas as pd

df = pd.DataFrame({
    'a': [1, 2, 3, 4],
    'b': [True, None, False, True],
    'c': [42, 21, 13, 14]
})
```

Selecting a single column:

```
col = duckdb.ColumnExpression('a')
duckdb.df(df).select(col).show()
```

```
┌─────────┐
│    a    │
│  int64  │
├─────────┤
│       1 │
│       2 │
│       3 │
│       4 │
└─────────┘
```

Selecting multiple columns:

```
col_list = [
        duckdb.ColumnExpression('a') * 10,
        duckdb.ColumnExpression('b').isnull(),
        duckdb.ColumnExpression('c') + 5
    ]
duckdb.df(df).select(*col_list).show()
```

```
┌──────────────┬──────────────────┬──────────────┐
│ (a * 10)     │ (b IS NULL)      │ (c + 5)      │
│  int64       │  boolean         │  int64       │
├──────────────┼──────────────────┼──────────────┤
│           10 │ false            │           47 │
│           20 │ true             │           26 │
│           30 │ false            │           18 │
│           40 │ false            │           19 │
└──────────────┴──────────────────┴──────────────┘
```

Star Expression

This expression selects all columns of the input source.

Optionally it's possible to provide an `exclude` list to filter out columns of the table. This `exclude` list can contain either strings or Expressions.

```
import duckdb
import pandas as pd

df = pd.DataFrame({
    'a': [1, 2, 3, 4],
    'b': [True, None, False, True],
    'c': [42, 21, 13, 14]
```

```
})

star = duckdb.StarExpression(exclude = ['b'])
duckdb.df(df).select(star).show()
```

```
┌─────────┬─────────┐
│    a    │    c    │
│  int64  │  int64  │
├─────────┼─────────┤
│       1 │      42 │
│       2 │      21 │
│       3 │      13 │
│       4 │      14 │
└─────────┴─────────┘
```

Constant Expression

This expression contains a single value.

```
import duckdb
import pandas as pd

df = pd.DataFrame({
    'a': [1, 2, 3, 4],
    'b': [True, None, False, True],
    'c': [42, 21, 13, 14]
})

const = duckdb.ConstantExpression('hello')
duckdb.df(df).select(const).show()
```

```
┌─────────┐
│ 'hello' │
│ varchar │
├─────────┤
│ hello   │
│ hello   │
│ hello   │
│ hello   │
└─────────┘
```

Case Expression

This expression contains a `CASE WHEN (...) THEN (...) ELSE (...) END` expression. By default `ELSE` is `NULL` and it can be set using `.else(value = ...)`. Additional `WHEN (...) THEN (...)` blocks can be added with `.when(condition = ..., value = ...)`.

```
import duckdb
import pandas as pd
from duckdb import (
    ConstantExpression,
    ColumnExpression,
    CaseExpression
)

df = pd.DataFrame({
    'a': [1, 2, 3, 4],
    'b': [True, None, False, True],
```

```
    'c': [42, 21, 13, 14]
})

hello = ConstantExpression('hello')
world = ConstantExpression('world')

case = \
    CaseExpression(condition = ColumnExpression('b') == False, value = world) \
    .otherwise(hello)
duckdb.df(df).select(case).show()
```

```
┌─────────────────────────────────────────────────────┐
│ CASE  WHEN ((b = false)) THEN ('world') ELSE 'hello' END │
│                        varchar                      │
├─────────────────────────────────────────────────────┤
│ hello                                               │
│ hello                                               │
│ world                                               │
│ hello                                               │
└─────────────────────────────────────────────────────┘
```

Function Expression

This expression contains a function call. It can be constructed by providing the function name and an arbitrary amount of Expressions as arguments.

```
import duckdb
import pandas as pd
from duckdb import (
    ConstantExpression,
    ColumnExpression,
    FunctionExpression
)

df = pd.DataFrame({
    'a': [1, 2, 3, 4],
    'b': [True, None, False, True],
    'c': [42, 21, 13, 14]
})

multiply_by_2 = FunctionExpression('multiply', ColumnExpression('a'), ConstantExpression(2))
duckdb.df(df).select(multiply_by_2).show()
```

```
┌──────────────┐
│ multiply(a, 2) │
│     int64      │
├──────────────┤
│            2 │
│            4 │
│            6 │
│            8 │
└──────────────┘
```

SQL Expression

This expression contains any valid SQL expression.

```
import duckdb
```

```
import pandas as pd

from duckdb import SQLExpression

df = pd.DataFrame({
    'a': [1, 2, 3, 4],
    'b': [True, None, False, True],
    'c': [42, 21, 13, 14]
})

duckdb.df(df).filter(
    SQLExpression("b is true")
).select(
    SQLExpression("a").alias("selecting_column_a"),
    SQLExpression("case when a = 1 then 1 else 0 end").alias("selecting_case_expression"),
    SQLExpression("1").alias("constant_numeric_column"),
    SQLExpression("'hello'").alias("constant_text_column")
).aggregate(
    aggr_expr=[
        SQLExpression("SUM(selecting_column_a)").alias("sum_a"),
        "selecting_case_expression" ,
        "constant_numeric_column",
        "constant_text_column"
    ],
).show()
```

sum_a int128	selecting_case_expression int32	constant_numeric_column int32	constant_text_column varchar
4	0	1	hello
1	1	1	hello

Common Operations

The Expression class also contains many operations that can be applied to any Expression type.

Operation	Description
`.alias(name: str)`	Applies an alias to the expression
`.cast(type: DuckDBPyType)`	Applies a cast to the provided type on the expression
`.isin(*exprs: Expression)`	Creates an `IN` expression against the provided expressions as the list
`.isnotin(*exprs: Expression)`	Creates a `NOT IN` expression against the provided expressions as the list
`.isnotnull()`	Checks whether the expression is not `NULL`
`.isnull()`	Checks whether the expression is `NULL`

Order Operations

When expressions are provided to `DuckDBPyRelation.order()`, the following order operations can be applied.

Operation	Description
`.asc()`	Indicates that this expression should be sorted in ascending order
`.desc()`	Indicates that this expression should be sorted in descending order
`.nulls_first()`	Indicates that the nulls in this expression should precede the non-null values
`.nulls_last()`	Indicates that the nulls in this expression should come after the non-null values

Spark API

The DuckDB Spark API implements the PySpark API, allowing you to use the familiar Spark API to interact with DuckDB. All statements are translated to DuckDB's internal plans using our relational API and executed using DuckDB's query engine.

> **Warning.** The DuckDB Spark API is currently experimental and features are still missing. We are very interested in feedback. Please report any functionality that you are missing, either through Discord or on GitHub.

Example

```
from duckdb.experimental.spark.sql import SparkSession as session
from duckdb.experimental.spark.sql.functions import lit, col
import pandas as pd

spark = session.builder.getOrCreate()

pandas_df = pd.DataFrame({
    'age': [34, 45, 23, 56],
    'name': ['Joan', 'Peter', 'John', 'Bob']
})

df = spark.createDataFrame(pandas_df)
df = df.withColumn(
    'location', lit('Seattle')
)
res = df.select(
    col('age'),
    col('location')
).collect()

print(res)
```

```
[
    Row(age=34, location='Seattle'),
    Row(age=45, location='Seattle'),
    Row(age=23, location='Seattle'),
    Row(age=56, location='Seattle')
]
```

Contribution Guidelines

Contributions to the experimental Spark API are welcome. When making a contribution, please follow these guidelines:

- Instead of using temporary files, use our `pytest` testing framework.
- When adding new functions, ensure that method signatures comply with those in the PySpark API.

Python Client API

Troubleshooting

Troubleshooting

Running `EXPLAIN` Renders Newlines

In Python, the output of the `EXPLAIN` statement contains hard line breaks (`\n`):

```
In [1]: import duckdb
   ...: duckdb.sql("EXPLAIN SELECT 42 AS x")
```

```
Out[1]:
```

```
┌─────────────┬──────────────
```

Parameterized Queries in Relational API

Passing query parameters to the `sql()`, `query()`, or `from_query()` methods has significant performance overhead. There is currently no relation type in core that supports prepared statements, so parameterized queries are immediately materialized into an intermediate representation. This causes at least 5x processing overhead and nearly 2x memory usage compared to the non-parameterized path.

Instead, use `execute()` for the parameterized query, then feed the result into the relational API via a replacement scan:

```
import duckdb

conn = duckdb.connect()

# Use execute() for the parameterized query
df = conn.execute("SELECT * FROM my_table WHERE x = ?", [42]).df()

# Use a replacement scan to continue with the relational API
conn.sql("SELECT * FROM df WHERE y > 0").order("y").show()
```

Known Issues

Unfortunately there are some issues that are either beyond our control or are very elusive / hard to track down. Below is a list of these issues that you might have to be aware of, depending on your workflow.

Numpy Import Multithreading

When making use of multi threading and fetching results either directly as Numpy arrays or indirectly through a Pandas DataFrame, it might be necessary to ensure that `numpy.core.multiarray` is imported. If this module has not been imported from the main thread, and a different thread during execution attempts to import it this causes either a deadlock or a crash.

To avoid this, it's recommended to `import numpy.core.multiarray` before starting up threads.

DESCRIBE and SUMMARIZE Return Empty Tables in Jupyter

The `DESCRIBE` and `SUMMARIZE` statements return an empty table:

```
%sql
CREATE OR REPLACE TABLE tbl AS (SELECT 42 AS x);
DESCRIBE tbl;
```

To work around this, wrap them into a subquery:

```
%sql
CREATE OR REPLACE TABLE tbl AS (SELECT 42 AS x);
FROM (DESCRIBE tbl);
```

Protobuf Error for JupySQL in IPython

Loading the JupySQL extension in IPython fails:

```
In [1]: %load_ext sql
```

```
ImportError: cannot import name 'builder' from 'google.protobuf.internal' (unknown location)
```

The solution is to fix the `protobuf` package. This may require uninstalling conflicting packages, e.g.:

```
%pip uninstall tensorflow
%pip install protobuf
```

R Client

> Installation To use the DuckDB R client, visit the R installation page.
>
> The latest stable version of the DuckDB R client is {% if site.current_duckdb_r_version != "" %}{{ site.current_duckdb_r_version }}{% else %}{{ site.lts_duckdb_r_version }}{% endif %}

Installation

duckdb: R Client

The DuckDB R client can be installed using the following command:

```
install.packages("duckdb")
```

Please see the installation page for details.

duckplyr: dplyr Client

DuckDB offers a dplyr-compatible API via the `duckplyr` package. It can be installed using `install.packages("duckplyr")`. For details, see the `duckplyr` documentation.

Reference Manual

The reference manual for the DuckDB R client is available at r.duckdb.org.

Basic Client Usage

The standard DuckDB R client implements the DBI interface for R. If you are not familiar with DBI yet, see the Using DBI page for an introduction.

Startup & Shutdown

To use DuckDB, you must first create a connection object that represents the database. The connection object takes as parameter the database file to read and write from. If the database file does not exist, it will be created (the file extension may be `.db`, `.duckdb`, or anything else). The special value `:memory:` (the default) can be used to create an **in-memory database**. Note that for an in-memory database no data is persisted to disk (i.e., all data is lost when you exit the R process). If you would like to connect to an existing database in read-only mode, set the `read_only` flag to TRUE. Read-only mode is required if multiple R processes want to access the same database file at the same time.

```
library("duckdb")
# to start an in-memory database
con <- dbConnect(duckdb())
# or
con <- dbConnect(duckdb(), dbdir = ":memory:")
# to use a database file (not shared between processes)
con <- dbConnect(duckdb(), dbdir = "my-db.duckdb", read_only = FALSE)
# to use a database file (shared between processes)
con <- dbConnect(duckdb(), dbdir = "my-db.duckdb", read_only = TRUE)
```

Connections are closed implicitly when they go out of scope or if they are explicitly closed using `dbDisconnect()`. To shut down the database instance associated with the connection, use `dbDisconnect(con, shutdown = TRUE)`

Querying

DuckDB supports the standard DBI methods to send queries and retrieve result sets. `dbExecute()` is meant for queries where no results are expected like `CREATE TABLE` or `UPDATE` etc. and `dbGetQuery()` is meant to be used for queries that produce results (e.g., `SELECT`). Below is an example.

```
# create a table
dbExecute(con, "CREATE TABLE items (item VARCHAR, value DECIMAL(10, 2), count INTEGER)")
# insert two items into the table
dbExecute(con, "INSERT INTO items VALUES ('jeans', 20.0, 1), ('hammer', 42.2, 2)")

# retrieve the items again
res <- dbGetQuery(con, "SELECT * FROM items")
print(res)
#     item value count
# 1  jeans  20.0     1
# 2 hammer  42.2     2
```

DuckDB also supports prepared statements in the R client with the `dbExecute` and `dbGetQuery` methods. Here is an example:

```
# prepared statement parameters are given as a list
dbExecute(con, "INSERT INTO items VALUES (?, ?, ?)", list('laptop', 2000, 1))

# if you want to reuse a prepared statement multiple times, use dbSendStatement() and dbBind()
stmt <- dbSendStatement(con, "INSERT INTO items VALUES (?, ?, ?)")
dbBind(stmt, list('iphone', 300, 2))
dbBind(stmt, list('android', 3.5, 1))
dbClearResult(stmt)

# query the database using a prepared statement
res <- dbGetQuery(con, "SELECT item FROM items WHERE value > ?", list(400))
print(res)
#       item
# 1 laptop
```

> **Warning.** Do **not** use prepared statements to insert large amounts of data into DuckDB. See below for better options.

Efficient Transfer

To write a R data frame into DuckDB, use the standard DBI function `dbWriteTable()`. This creates a table in DuckDB and populates it with the data frame contents. For example:

```
dbWriteTable(con, "iris_table", iris)
res <- dbGetQuery(con, "SELECT * FROM iris_table LIMIT 1")
print(res)
#   Sepal.Length Sepal.Width Petal.Length Petal.Width Species
# 1          5.1         3.5          1.4         0.2  setosa
```

It is also possible to "register" a R data frame as a virtual table, comparable to a SQL `VIEW`. This *does not actually transfer data* into DuckDB yet. Below is an example:

```
duckdb_register(con, "iris_view", iris)
res <- dbGetQuery(con, "SELECT * FROM iris_view LIMIT 1")
print(res)
#   Sepal.Length Sepal.Width Petal.Length Petal.Width Species
# 1          5.1         3.5          1.4         0.2  setosa
```

> DuckDB keeps a reference to the R data frame after registration. This prevents the data frame from being garbage-collected. The reference is cleared when the connection is closed, but can also be cleared manually using the `duckdb_unregister()` method.

Also refer to the data import documentation for more options of efficiently importing data.

dbplyr

DuckDB also plays well with the dbplyr / dplyr packages for programmatic query construction from R. Here is an example:

```
library("duckdb")
library("dplyr")
con <- dbConnect(duckdb())
duckdb_register(con, "flights", nycflights13::flights)

tbl(con, "flights") |>
  group_by(dest) |>
  summarise(delay = mean(dep_time, na.rm = TRUE)) |>
  collect()
```

When using dbplyr, CSV and Parquet files can be read using the `dplyr::tbl` function.

```
# Establish a CSV for the sake of this example
write.csv(mtcars, "mtcars.csv")

# Summarize the dataset in DuckDB to avoid reading the entire CSV into R's memory
tbl(con, "mtcars.csv") |>
  group_by(cyl) |>
  summarise(across(disp:wt, .fns = mean)) |>
  collect()

# Establish a set of Parquet files
dbExecute(con, "COPY flights TO 'dataset' (FORMAT parquet, PARTITION_BY (year, month))")

# Summarize the dataset in DuckDB to avoid reading 12 Parquet files into R's memory
tbl(con, "read_parquet('dataset/**/*.parquet', hive_partitioning = true)") |>
  filter(month == "3") |>
  summarise(delay = mean(dep_time, na.rm = TRUE)) |>
  collect()
```

Memory Limit

You can use the `memory_limit` configuration option to limit the memory use of DuckDB, e.g.:

```
SET memory_limit = '2GB';
```

Note that this limit is only applied to the memory DuckDB uses and it does not affect the memory use of other R libraries. Therefore, the total memory used by the R process may be higher than the configured `memory_limit`.

Troubleshooting

Warning When Installing on macOS

On macOS, installing DuckDB may result in a warning `unable to load shared object '.../R_X11.so'`:

```
Warning message:
In doTryCatch(return(expr), name, parentenv, handler) :
  unable to load shared object '/Library/Frameworks/R.framework/Resources/modules//R_X11.so':
```

```
  dlopen(/Library/Frameworks/R.framework/Resources/modules//R_X11.so, 0x0006): Library not loaded:
/opt/X11/lib/libSM.6.dylib
  Referenced from: <31EADEB5-0A17-3546-9944-9B3747071FE8>
/Library/Frameworks/R.framework/Versions/4.4-arm64/Resources/modules/R_X11.so
  Reason: tried: '/opt/X11/lib/libSM.6.dylib' (no such file) ...
> ')
```

Note that this is just a warning, so the simplest solution is to ignore it. Alternatively, you can install DuckDB from the R-universe:

```r
install.packages("duckdb", repos = c("https://duckdb.r-universe.dev", "https://cloud.r-project.org"))
```

You may also install the optional `xquartz` dependency via Homebrew.

Rust Client

> Installation To use the DuckDB Rust client, visit the Rust installation page.
>
> The latest stable version of the DuckDB Rust client is {% if site.current_duckdb_rust_version != "" %}{{ site.current_duckdb_rust_version }}{% else %}{{ site.lts_duckdb_rust_version }}{% endif %}.

Installation

The DuckDB Rust client can be installed from crates.io. Please see the docs.rs for details.

Basic API Usage

duckdb-rs is an ergonomic wrapper based on the DuckDB C API, please refer to the README for details.

Startup & Shutdown

To use duckdb, you must first initialize a `Connection` handle using `Connection::open()`. `Connection::open()` takes as parameter the database file to read and write from. If the database file does not exist, it will be created (the file extension may be `.db`, `.duckdb`, or anything else). You can also use `Connection::open_in_memory()` to create an **in-memory database**. Note that for an in-memory database no data is persisted to disk (i.e., all data is lost when you exit the process).

```
use duckdb::{params, Connection, Result};
let conn = Connection::open_in_memory()?;
```

The `Connection` will automatically close the underlying db connection for you when it goes out of scope (via `Drop`). You can also explicitly close the `Connection` with `conn.close()`. There is not much difference between these in the typical case, but in case there is an error, you'll have the chance to handle it with the explicit close.

Querying

SQL queries can be sent to DuckDB using the `execute()` method of connections, or we can also prepare the statement and then query on that.

```
#[derive(Debug)]
struct Person {
    id: i32,
    name: String,
    data: Option<Vec<u8>>,
}

conn.execute(
    "INSERT INTO person (name, data) VALUES (?, ?)",
    params![me.name, me.data],
)?;

let mut stmt = conn.prepare("SELECT id, name, data FROM person")?;
let person_iter = stmt.query_map([], |row| {
    Ok(Person {
```

```
        id: row.get(0)?,
        name: row.get(1)?,
        data: row.get(2)?,
    })
})?;

for person in person_iter {
    println!("Found person {:?}", person.unwrap());
}
```

Appender

The Rust client supports the DuckDB Appender API for bulk inserts. For example:

```
fn insert_rows(conn: &Connection) -> Result<()> {
    let mut app = conn.appender("foo")?;
    app.append_rows([[1, 2], [3, 4], [5, 6], [7, 8], [9, 10]])?;
    Ok(())
}
```

Wasm

DuckDB Wasm

> Installation To use the DuckDB Wasm client, visit the duckdb-wasm GitHub repository.
>
> The latest stable version of the DuckDB WebAssembly client is {% if site.current_duckdb_wasm_version != "" %}{{ site.current_duckdb_wasm_version }}{% else %}{{ site.lts_duckdb_wasm_version }}{% endif %}.

DuckDB has been compiled to WebAssembly, so it can run inside any browser on any device.

DuckDB-Wasm offers a layered API, it can be embedded as a JavaScript + WebAssembly library, as a Web shell, or built from source according to your needs.

Getting Started with DuckDB-Wasm

A great starting point is to read the DuckDB-Wasm launch blog post!

Another great resource is the GitHub repository.

For details, see the full DuckDB-Wasm API Documentation.

Limitations

- By default, the WebAssembly client only uses a single thread.
- The WebAssembly client has a limited amount of memory available. WebAssembly limits the amount of available memory to 4 GB and browsers may impose even stricter limits.

Deploying DuckDB-Wasm

A DuckDB-Wasm deployment needs to access the following components:

- the DuckDB-Wasm main library component, distributed as TypeScript and compiled to JavaScript code
- the DuckDB-Wasm Worker component, compiled to JavaScript code, possibly instantiated multiple times for threaded environments
- the DuckDB-Wasm module, compiled as a WebAssembly file and instantiated by the browser
- any relevant DuckDB-Wasm extension

Main Library Component

This is distributed as either TypeScript code or CommonJS JavaScript code in the npm duckdb-wasm package, and can be either bundled together with a given application, served in a same origin (sub-)domain and included at runtime or served from a third party CDN like jsDelivr. This does need some form of transpilation and can't be served as-is, given it needs to know the location of the follow up files for this to be functional. Details will depend on your given setup, examples can be found at https://github.com/duckdb/duckdb-wasm/tree/main/examples. An example deployment is https://shell.duckdb.org, which transpiles the main library component together with shell code (first approach). Or the bare-browser example at https://github.com/duckdb/duckdb-wasm/tree/main/examples/bare-browser.

JS Worker Component

This is distributed as a JavaScript file in 3 different flavors, `mvp`, `eh` and `threads`, and needs to be served as is. The main library components need to be informed of the actual location.

There are 3 variants for 3 different `platforms`:

- `mvp` targets WebAssembly 1.0 spec
- `eh` targets WebAssembly 1.0 spec WITH Wasm-level exceptions handling added, which improves performance
- `threads` targets WebAssembly spec WITH exception and threading constructs

You could serve all 3, and feature detect, or serve a single variant and instruct duckdb-wasm library on which one to use

Wasm Worker Component

Same as the JS Worker component, 3 different flavors, `mvp`, `eh` and `threads`, each one is needed by the relevant JS component. These WebAssembly modules need to be served as-is at an arbitrary [sub-] domain that is reachable from the main one.

DuckDB Extensions

DuckDB extensions for DuckDB-Wasm, similar for the native cases, are served signed at the default extension endpoint: `https://extensions.duckdb.org`. If you are deploying duckdb-wasm you can consider mirroring relevant extensions at a different endpoint, possibly allowing for air-tight deployments on internal networks.

```
SET custom_extension_repository = '<https://some.endpoint.org/path/to/repository>';
```

Changes the default extension repository from the public `https://extensions.duckdb.org` to the one specified. Note that extensions are still signed, so the best path is downloading and serving the extensions with a similar structure to the original repository. See our additional notes on Creating a Custom Repository.

Community extensions are served at https://community-extensions.duckdb.org, and they are signed with a different key, so they can be disabled with a one way SQL statement such as:

```
SET allow_community_extensions = false;
```

This will allow loading **only** of core duckdb extensions. Note that the failure is at `LOAD` time, not at `INSTALL` time.

Please review the Extension Distribution page for general information about extensions.

Security Considerations

> **Warning.** Deploying DuckDB-Wasm with access to your own data means whoever has access to SQL can access the data that DuckDB-Wasm can access. Also, DuckDB-Wasm in the default setting can access remote endpoints, so it can have a visible effect on the external world even from within the sandbox.

Instantiation

DuckDB-Wasm has multiple ways to be instantiated depending on the use case.

`cdn(jsdelivr)`

```
import * as duckdb from '@duckdb/duckdb-wasm';

const JSDELIVR_BUNDLES = duckdb.getJsDelivrBundles();
```

```
// Select a bundle based on browser checks
const bundle = await duckdb.selectBundle(JSDELIVR_BUNDLES);

const worker_url = URL.createObjectURL(
  new Blob([`importScripts("${bundle.mainWorker}");`], {type: 'text/javascript'})
);

// Instantiate the asynchronous version of DuckDB-Wasm
const worker = new Worker(worker_url);
const logger = new duckdb.ConsoleLogger();
const db = new duckdb.AsyncDuckDB(logger, worker);
await db.instantiate(bundle.mainModule, bundle.pthreadWorker);
URL.revokeObjectURL(worker_url);
```

webpack

```
import * as duckdb from '@duckdb/duckdb-wasm';
import duckdb_wasm from '@duckdb/duckdb-wasm/dist/duckdb-mvp.wasm';
import duckdb_wasm_next from '@duckdb/duckdb-wasm/dist/duckdb-eh.wasm';
const MANUAL_BUNDLES: duckdb.DuckDBBundles = {
    mvp: {
        mainModule: duckdb_wasm,
        mainWorker: new URL('@duckdb/duckdb-wasm/dist/duckdb-browser-mvp.worker.js',
import.meta.url).toString(),
    },
    eh: {
        mainModule: duckdb_wasm_next,
        mainWorker: new URL('@duckdb/duckdb-wasm/dist/duckdb-browser-eh.worker.js',
import.meta.url).toString(),
    },
};
// Select a bundle based on browser checks
const bundle = await duckdb.selectBundle(MANUAL_BUNDLES);
// Instantiate the asynchronous version of DuckDB-Wasm
const worker = new Worker(bundle.mainWorker!);
const logger = new duckdb.ConsoleLogger();
const db = new duckdb.AsyncDuckDB(logger, worker);
await db.instantiate(bundle.mainModule, bundle.pthreadWorker);
```

vite

```
import * as duckdb from '@duckdb/duckdb-wasm';
import duckdb_wasm from '@duckdb/duckdb-wasm/dist/duckdb-mvp.wasm?url';
import mvp_worker from '@duckdb/duckdb-wasm/dist/duckdb-browser-mvp.worker.js?url';
import duckdb_wasm_eh from '@duckdb/duckdb-wasm/dist/duckdb-eh.wasm?url';
import eh_worker from '@duckdb/duckdb-wasm/dist/duckdb-browser-eh.worker.js?url';

const MANUAL_BUNDLES: duckdb.DuckDBBundles = {
    mvp: {
        mainModule: duckdb_wasm,
        mainWorker: mvp_worker,
    },
    eh: {
        mainModule: duckdb_wasm_eh,
        mainWorker: eh_worker,
    },
```

```
};
// Select a bundle based on browser checks
const bundle = await duckdb.selectBundle(MANUAL_BUNDLES);
// Instantiate the asynchronous version of DuckDB-wasm
const worker = new Worker(bundle.mainWorker!);
const logger = new duckdb.ConsoleLogger();
const db = new duckdb.AsyncDuckDB(logger, worker);
await db.instantiate(bundle.mainModule, bundle.pthreadWorker);
```

Statically Served

It is possible to manually download the files from https://cdn.jsdelivr.net/npm/@duckdb/duckdb-wasm/dist/.

```
import * as duckdb from '@duckdb/duckdb-wasm';

const MANUAL_BUNDLES: duckdb.DuckDBBundles = {
    mvp: {
        mainModule: 'change/me/../duckdb-mvp.wasm',
        mainWorker: 'change/me/../duckdb-browser-mvp.worker.js',
    },
    eh: {
        mainModule: 'change/m/../duckdb-eh.wasm',
        mainWorker: 'change/m/../duckdb-browser-eh.worker.js',
    },
};
// Select a bundle based on browser checks
const bundle = await duckdb.selectBundle(MANUAL_BUNDLES);
// Instantiate the asynchronous version of DuckDB-Wasm
const worker = new Worker(bundle.mainWorker!);
const logger = new duckdb.ConsoleLogger();
const db = new duckdb.AsyncDuckDB(logger, worker);
await db.instantiate(bundle.mainModule, bundle.pthreadWorker);
```

Data Ingestion

DuckDB-Wasm has multiple ways to import data, depending on the format of the data.

There are two steps to import data into DuckDB.

First, the data file is imported into a local file system using register functions (registerEmptyFileBuffer, registerFileBuffer, registerFileHandle, registerFileText, registerFileURL).

Then, the data file is imported into DuckDB using insert functions (insertArrowFromIPCStream, insertArrowTable, insertCSVFromPath, insertJSONFromPath) or directly using FROM SQL query (using extensions like Parquet or Wasm-flavored httpfs).

Insert statements can also be used to import data.

Data Import

Open & Close Connection

```
// Create a new connection
const c = await db.connect();

// ... import data

// Close the connection to release memory
await c.close();
```

Apache Arrow

```
// Data can be inserted from an existing arrow.Table
// More Example https://arrow.apache.org/docs/js/
import { tableFromArrays } from 'apache-arrow';

// EOS signal according to Arrow IPC streaming format
// See https://arrow.apache.org/docs/format/Columnar.html#ipc-streaming-format
const EOS = new Uint8Array([255, 255, 255, 255, 0, 0, 0, 0]);

const arrowTable = tableFromArrays({
  id: [1, 2, 3],
  name: ['John', 'Jane', 'Jack'],
  age: [20, 21, 22],
});

await c.insertArrowTable(arrowTable, { name: 'arrow_table' });
// Write EOS
await c.insertArrowTable(EOS, { name: 'arrow_table' });

// ..., from a raw Arrow IPC stream
const streamResponse = await fetch(` someapi`);
const streamReader = streamResponse.body.getReader();
const streamInserts = [];
while (true) {
    const { value, done } = await streamReader.read();
    if (done) break;
    streamInserts.push(c.insertArrowFromIPCStream(value, { name: 'streamed' }));
}

// Write EOS
streamInserts.push(c.insertArrowFromIPCStream(EOS, { name: 'streamed' }));

await Promise.all(streamInserts);
```

CSV

```
// ..., from CSV files
// (interchangeable: registerFile{Text,Buffer,URL,Handle})
const csvContent = '1|foo\n2|bar\n';
await db.registerFileText(` data.csv`, csvContent);
// ... with typed insert options
await c.insertCSVFromPath('data.csv', {
    schema: 'main',
    name: 'foo',
    detect: false,
    header: false,
    delimiter: '|',
    columns: {
        col1: new arrow.Int32(),
        col2: new arrow.Utf8(),
    },
});
```

JSON

```
// ..., from JSON documents in row-major format
const jsonRowContent = [
```

```
    { "col1": 1, "col2": "foo" },
    { "col1": 2, "col2": "bar" },
];
await db.registerFileText(
    'rows.json',
    JSON.stringify(jsonRowContent),
);
await c.insertJSONFromPath('rows.json', { name: 'rows' });

// ... or column-major format
const jsonColContent = {
    "col1": [1, 2],
    "col2": ["foo", "bar"]
};
await db.registerFileText(
    'columns.json',
    JSON.stringify(jsonColContent),
);
await c.insertJSONFromPath('columns.json', { name: 'columns' });

// From API
const streamResponse = await fetch(` someapi/content.json`);
await db.registerFileBuffer('file.json', new Uint8Array(await streamResponse.arrayBuffer()))
await c.insertJSONFromPath('file.json', { name: 'JSONContent' });
```

Parquet

```
// from Parquet files
// ...Local
const pickedFile: File = letUserPickFile();
await db.registerFileHandle('local.parquet', pickedFile, DuckDBDataProtocol.BROWSER_FILEREADER, true);
// ...Remote
await db.registerFileURL('remote.parquet', 'https://origin/remote.parquet', DuckDBDataProtocol.HTTP,
false);
// ... Using Fetch
const res = await fetch('https://origin/remote.parquet');
await db.registerFileBuffer('buffer.parquet', new Uint8Array(await res.arrayBuffer()));

// ..., by specifying URLs in the SQL text
await c.query(`
    CREATE TABLE direct AS
        SELECT * FROM 'https://origin/remote.parquet'
`);
// ..., or by executing raw insert statements
await c.query(`
    INSERT INTO existing_table
    VALUES (1, 'foo'), (2, 'bar')`);
```

httpfs (Wasm-Flavored)

```
// ..., by specifying URLs in the SQL text
await c.query(`
    CREATE TABLE direct AS
        SELECT * FROM 'https://origin/remote.parquet'
`);
```

> **Tip.** If you encounter a Network Error (`Failed to execute 'send' on 'XMLHttpRequest'`) when you try to query files from S3, configure the S3 permission CORS header. For example:

```
[
    {
        "AllowedHeaders": [
            "*"
        ],
        "AllowedMethods": [
            "GET",
            "HEAD"
        ],
        "AllowedOrigins": [
            "*"
        ],
        "ExposeHeaders": [],
        "MaxAgeSeconds": 3000
    }
]
```

Insert Statement

```
// ..., or by executing raw insert statements
await c.query(`
    INSERT INTO existing_table
    VALUES (1, 'foo'), (2, 'bar')`);
```

Query

DuckDB-Wasm provides functions for querying data. Queries are run sequentially.

First, a connection needs to be created by calling connect. Then, queries can be run by calling query or send.

Query Execution

```
// Create a new connection
const conn = await db.connect();

// Either materialize the query result
await conn.query<{ v: arrow.Int }>(`
    SELECT * FROM generate_series(1, 100) t(v)
`);
// ..., or fetch the result chunks lazily
for await (const batch of await conn.send<{ v: arrow.Int }>(`
    SELECT * FROM generate_series(1, 100) t(v)
`)) {
    // ...
}

// Close the connection to release memory
await conn.close();
```

Prepared Statements

```
// Create a new connection
```

```
const conn = await db.connect();
// Prepare query
const stmt = await conn.prepare(` SELECT v + ? FROM generate_series(0, 10_000) t(v);`);
// ... and run the query with materialized results
await stmt.query(234);
// ... or result chunks
for await (const batch of await stmt.send(234)) {
    // ...
}
// Close the statement to release memory
await stmt.close();
// Closing the connection will release statements as well
await conn.close();
```

Arrow Table to JSON

```
// Create a new connection
const conn = await db.connect();

// Query
const arrowResult = await conn.query<{ v: arrow.Int }>(`
    SELECT * FROM generate_series(1, 100) t(v)
`);

// Convert arrow table to json
const result = arrowResult.toArray().map((row) => row.toJSON());

// Close the connection to release memory
await conn.close();
```

Export Parquet

```
// Create a new connection
const conn = await db.connect();

// Export Parquet
conn.send(` COPY (SELECT * FROM tbl) TO 'result-snappy.parquet' (FORMAT parquet);`);
const parquet_buffer = await this._db.copyFileToBuffer('result-snappy.parquet');

// Generate a download link
const link = URL.createObjectURL(new Blob([parquet_buffer]));

// Close the connection to release memory
await conn.close();
```

Extensions

DuckDB-Wasm's (dynamic) extension loading is modeled after the regular DuckDB's extension loading, with a few relevant differences due to the difference in platform.

Format

Extensions in DuckDB are binaries to be dynamically loaded via `dlopen`. A cryptographical signature is appended to the binary. An extension in DuckDB-Wasm is a regular Wasm file to be dynamically loaded via Emscripten's `dlopen`. A cryptographical signature is appended to the Wasm file as a WebAssembly custom section called `duckdb_signature`. This ensures the file remains a valid WebAssembly file.

> Currently, we require this custom section to be the last one, but this can be potentially relaxed in the future.

`INSTALL` and `LOAD`

The `INSTALL` semantic in native embeddings of DuckDB is to fetch, decompress from `gzip` and store data in local disk. The `LOAD` semantic in native embeddings of DuckDB is to (optionally) perform signature checks *and* dynamic load the binary with the main DuckDB binary.

In DuckDB-Wasm, `INSTALL` is a no-op given there is no durable cross-session storage. The `LOAD` operation will fetch (and decompress on the fly), perform signature checks *and* dynamically load via the Emscripten implementation of `dlopen`.

Autoloading

Autoloading, i.e., the possibility for DuckDB to add extension functionality on-the-fly, is enabled by default in DuckDB-Wasm.

List of Officially Available Extensions

Extension name	Description	Aliases
autocomplete	Adds support for autocomplete in the shell	
excel	Adds support for Excel-like format strings	
fts	Adds support for Full-Text Search Indexes	
icu	Adds support for time zones and collations using the ICU library	
inet	Adds support for IP-related data types and functions	
json	Adds support for JSON operations	
parquet	Adds support for reading and writing Parquet files	
sqlite	Adds support for reading SQLite database files	sqlite, sqlite3
sqlsmith		
tpcds	Adds TPC-DS data generation and query support	
tpch	Adds TPC-H data generation and query support	

WebAssembly is basically an additional platform, and there might be platform-specific limitations that make some extensions not able to match their native capabilities or to perform them in a different way. We will document here relevant differences for DuckDB-hosted extensions.

HTTPFS

The HTTPFS extension is, at the moment, not available in DuckDB-Wasm. Https protocol capabilities need to go through an additional layer, the browser, which adds both differences and some restrictions to what is doable from native.

Instead, DuckDB-Wasm has a separate implementation that for most purposes is interchangeable, but does not support all use cases (as it must follow security rules imposed by the browser, such as CORS). Due to this CORS restriction, any requests for data made using the HTTPFS extension must be to websites that allow (using CORS headers) the website hosting the DuckDB-Wasm instance to access that data. The MDN website is a great resource for more information regarding CORS.

Extension Signing

As with regular DuckDB extensions, DuckDB-Wasm extensions are by default checked on `LOAD` to verify the signature and confirm the extension has not been tampered with. Extension signature verification can be disabled via a configuration option. Signing is a property of the binary itself, so copying a DuckDB extension (say to serve it from a different location) will still keep a valid signature (e.g., for local development).

Fetching DuckDB-Wasm Extensions

Official DuckDB extensions are served at `extensions.duckdb.org`, and this is also the default value for the `default_extension_repository` option. When installing extensions, a relevant URL will be built that will look like `extensions.duckdb.org/$duckdb_version_hash/$duckdb_platform/$name.duckdb_extension.gz`.

DuckDB-Wasm extension are fetched only on load, and the URL will look like: `extensions.duckdb.org/duckdb-wasm/$duckdb_version_hash/$duckdb_platform/$name.duckdb_extension.wasm`.

Note that an additional `duckdb-wasm` is added to the folder structure, and the file is served as a `.wasm` file.

DuckDB-Wasm extensions are served pre-compressed using Brotli compression. While fetched from a browser, extensions will be transparently uncompressed. If you want to fetch the `duckdb-wasm` extension manually, you can use `curl --compress extensions.duckdb.org/<...>/icu.duckdb_extension.wasm`.

Serving Extensions from a Third-Party Repository

As with regular DuckDB, if you use `SET custom_extension_repository = 'https://some.url.com'`, subsequent loads will be attempted at `https://some.url.com/duckdb-wasm/$duckdb_version_hash/$duckdb_platform/$name.duckdb_extension.wasm`.

Note that GET requests on the extensions needs to be CORS enabled for a browser to allow the connection.

Tooling

Both DuckDB-Wasm and its extensions have been compiled using the latest packaged Emscripten toolchain.

Tertiary Clients

Tertiary Clients

The following table lists the **tertiary clients** of DuckDB. Tertiary clients come without any support guarantees.

Client API	Maintainer
Common Lisp	ak-coram
Crystal	amauryt
Dart	TigerEye
Elixir (Duckdbex)	AlexR2D2
Elixir (QuackDB)	Danila Poyarkov
Erlang	MM Zeeman
Haskell	Tritlo
Julia	The DuckDB team
Perl	Giuseppe Di Terlizzi
PHP	satur-io
Pyodide	The DuckDB team
Raku	bduggan
Ruby	suketa
Scala	Salar Rahmanian
Swift	The DuckDB team
Zig	karlseguin

Dart Client

> The latest stable version of the DuckDB Dart client is {% if site.current_duckdb_dart_version != "" %}{{ site.current_duckdb_dart_version }}{% else %}{{ site.lts_duckdb_dart_version }}{% endif %}.

DuckDB.Dart is the native Dart API for DuckDB.

Installation

DuckDB.Dart can be installed from pub.dev. Please see the API Reference for details.

Use This Package as a Library

Depend on It Add the dependency with Flutter:

```
flutter pub add dart_duckdb
```

This will add a line like this to your package's `pubspec.yaml` (and run an implicit `flutter pub get`):

```
dependencies:
  dart_duckdb: ^{{ site.current_duckdb_dart_version }}
```

Alternatively, your editor might support `flutter pub get`. Check the docs for your editor to learn more.

Import It Now in your Dart code, you can import it:

```
import 'package:dart_duckdb/dart_duckdb.dart';
```

Usage Examples

See the example projects in the `duckdb-dart` repository:

- `cli`: command-line application
- `duckdbexplorer`: GUI application which builds for desktop operating systems as well as Android and iOS.

Here are some common code snippets for DuckDB.Dart:

Querying an In-Memory Database

```
import 'package:dart_duckdb/dart_duckdb.dart';

void main() async {
  final db = await duckdb.open(":memory:");
  final connection = await duckdb.connect(db);

  await connection.execute('''
    CREATE TABLE users (id INTEGER, name VARCHAR, age INTEGER);
    INSERT INTO users VALUES (1, 'Alice', 30), (2, 'Bob', 25);
  ''');

  final result = (await connection.query("SELECT * FROM users WHERE age > 28")).fetchAll();

  for (final row in result) {
    print(row);
  }

  connection.dispose();
  db.dispose();
}
```

Using Multiple Connections

DuckDB.Dart automatically manages dedicated background isolates per connection, enabling efficient non-blocking I/O for concurrent queries. Each connection handles its own isolate internally, so you can simply create multiple connections for parallel operations:

```
import 'package:dart_duckdb/dart_duckdb.dart';

void main() async {
  final db = await duckdb.open(":memory:");

  // Create a table
  final con1 = await duckdb.connect(db);
```

```
  await con1.execute('''
    CREATE TABLE users (id INTEGER, name VARCHAR);
    INSERT INTO users VALUES (1, 'Alice'), (2, 'Bob');
  ''');

  // Query from multiple connections concurrently
  final con2 = await duckdb.connect(db);
  final con3 = await duckdb.connect(db);

  final future1 = con2.query("SELECT * FROM users WHERE id = 1");
  final future2 = con3.query("SELECT * FROM users WHERE id = 2");

  final result1 = (await future1).fetchAll();
  final result2 = (await future2).fetchAll();

  print(result1);
  print(result2);

  con1.dispose();
  con2.dispose();
  con3.dispose();
  db.dispose();
}
```

Web Support

DuckDB.Dart supports web platforms through DuckDB WASM. For Flutter web builds, you need to configure the necessary JavaScript dependencies.

Setup for Flutter Web

Add the following to `web/index.html` inside the `<head>` section to load DuckDB WASM and Apache Arrow:

```
<script type="importmap">
  {
    "imports": {
      "apache-arrow": "https://cdn.jsdelivr.net/npm/apache-arrow@17.0.0/+esm"
    }
  }
</script>
<script type="module">
  import * as duckdb from "https://cdn.jsdelivr.net/npm/@duckdb/duckdb-wasm@1.29.1-dev222.0/+esm";
  import * as arrow from "apache-arrow";
  window.duckdbWasmReady = new Promise((resolve) => {
    window.duckdbduckdbWasm = duckdb;
    window.ArrowTable = arrow.Table;
    resolve();
  });
</script>
```

Usage in Flutter Web

Once configured, you can use DuckDB the same way as on other platforms:

```
import 'package:dart_duckdb/dart_duckdb.dart';

void main() async {
```

```
  final db = await duckdb.open(":memory:");
  final connection = await duckdb.connect(db);

  await connection.execute('''
    CREATE TABLE data (id INTEGER, value VARCHAR);
    INSERT INTO data VALUES (1, 'hello'), (2, 'world');
  ''');

  final result = (await connection.query("SELECT * FROM data")).fetchAll();
  for (final row in result) {
    print(row);
  }

  connection.dispose();
  db.dispose();
}
```

For more platform-specific details, see the Building Instructions.

Julia Client

The DuckDB Julia package provides a high-performance front-end for DuckDB. Much like SQLite, DuckDB runs in-process within the Julia client, and provides a `DBInterface` front-end.

The package also supports multi-threaded execution. It uses Julia threads/tasks for this purpose. If you wish to run queries in parallel, you must launch Julia with multi-threading support (by e.g., setting the `JULIA_NUM_THREADS` environment variable).

Installation

Install DuckDB as follows:

```
using Pkg
Pkg.add("DuckDB")
```

Alternatively, enter the package manager using the `]` key, and issue the following command:

```
pkg> add DuckDB
```

Basics

```
using DuckDB

# create a new in-memory database
con = DBInterface.connect(DuckDB.DB, ":memory:")

# create a table
DBInterface.execute(con, "CREATE TABLE integers (i INTEGER)")

# insert data by executing a prepared statement
stmt = DBInterface.prepare(con, "INSERT INTO integers VALUES (?)")
DBInterface.execute(stmt, [42])

# query the database
results = DBInterface.execute(con, "SELECT 42 a")
print(results)
```

Some SQL statements, such as PIVOT and IMPORT DATABASE are executed as multiple prepared statements and will error when using `DuckDB.execute()`. Instead they can be run with `DuckDB.query()` instead of `DuckDB.execute()` and will always return a materialized result.

Scanning DataFrames

The DuckDB Julia package also provides support for querying Julia DataFrames. Note that the DataFrames are directly read by DuckDB – they are not inserted or copied into the database itself.

If you wish to load data from a DataFrame into a DuckDB table you can run a `CREATE TABLE ... AS` or `INSERT INTO` query.

```
using DuckDB
using DataFrames

# create a new in-memory database
con = DBInterface.connect(DuckDB.DB)

# create a DataFrame
df = DataFrame(a = [1, 2, 3], b = [42, 84, 42])

# register it as a view in the database
DuckDB.register_data_frame(con, df, "my_df")

# run a SQL query over the DataFrame
results = DBInterface.execute(con, "SELECT * FROM my_df")
print(results)
```

Appender API

The DuckDB Julia package also supports the Appender API, which is much faster than using prepared statements or individual `INSERT INTO` statements. Appends are made in row-wise format. For every column, an `append()` call should be made, after which the row should be finished by calling `flush()`. After all rows have been appended, `close()` should be used to finalize the Appender and clean up the resulting memory.

```
using DuckDB, DataFrames, Dates
db = DuckDB.DB()
# create a table
DBInterface.execute(db,
    "CREATE OR REPLACE TABLE data (id INTEGER PRIMARY KEY, value FLOAT, timestamp TIMESTAMP, date DATE)")
# create data to insert
len = 100
df = DataFrames.DataFrame(
        id = collect(1:len),
        value = rand(len),
        timestamp = Dates.now() + Dates.Second.(1:len),
        date = Dates.today() + Dates.Day.(1:len)
    )
# append data by row
appender = DuckDB.Appender(db, "data")
for i in eachrow(df)
    for j in i
        DuckDB.append(appender, j)
    end
    DuckDB.end_row(appender)
end
# close the appender after all rows
DuckDB.close(appender)
```

Concurrency

Within a Julia process, tasks are able to concurrently read and write to the database, as long as each task maintains its own connection to the database. In the example below, a single task is spawned to periodically read the database and many tasks are spawned to write to the database using both INSERT statements as well as the Appender API.

```
using Dates, DataFrames, DuckDB
db = DuckDB.DB()
DBInterface.connect(db)
DBInterface.execute(db, "CREATE OR REPLACE TABLE data (date TIMESTAMP, id INTEGER)")

function run_reader(db)
    # create a DuckDB connection specifically for this task
    conn = DBInterface.connect(db)
    while true
        println(DBInterface.execute(conn,
                "SELECT id, count(date) AS count, max(date) AS max_date
                FROM data GROUP BY id ORDER BY id") |> DataFrames.DataFrame)
        Threads.sleep(1)
    end
    DBInterface.close(conn)
end
# spawn one reader task
Threads.@spawn run_reader(db)

function run_inserter(db, id)
    # create a DuckDB connection specifically for this task
    conn = DBInterface.connect(db)
    for i in 1:1000
        Threads.sleep(0.01)
        DuckDB.execute(conn, "INSERT INTO data VALUES (current_timestamp, ?)"; id);
    end
    DBInterface.close(conn)
end
# spawn many insert tasks
for i in 1:100
    Threads.@spawn run_inserter(db, 1)
end

function run_appender(db, id)
    # create a DuckDB connection specifically for this task
    appender = DuckDB.Appender(db, "data")
    for i in 1:1000
        Threads.sleep(0.01)
        row = (Dates.now(Dates.UTC), id)
        for j in row
            DuckDB.append(appender, j);
        end
        DuckDB.end_row(appender);
    end
    DuckDB.close(appender);
end
# spawn many appender tasks
for i in 1:100
    Threads.@spawn run_appender(db, 2)
end
```

Original Julia Connector

Credits to kimmolinna for the original DuckDB Julia connector.

PHP Client

> The DuckDB PHP client is a tertiary client and is maintained by a third-party.

Client API for PHP, focused on performance. The DuckDB PHP client uses the official C API internally through FFI, achieving good benchmark results. This library is more than just a wrapper for the C API; it introduces custom, PHP-friendly methods to simplify working with DuckDB. It is compatible with Linux, Windows and macOS, requiring PHP version 8.3 or higher.

Full documentation is available at https://duckdb-php.readthedocs.io/.

Automatic Install (Recommended for Newcomers)

```
composer require satur.io/duckdb-auto
```

You will need to allow `satur.io/duckdb-auto` to execute code to use this installation method, check installation for more details.

Quick Start

```
DuckDB::sql("SELECT 'quack' as my_column")->print();
```

```
--------------------
| my_column        |
--------------------
| quack            |
--------------------
```

The function we used here, `DuckDB::sql()`, performs the query in a new in-memory database which is destroyed after retrieving the result.

This is not the most common use case, let's see how to get a persistent connection.

Connection

```
$duckDB = DuckDB::create('duck.db'); // or DuckDB::create() for in-memory database

$duckDB->query('CREATE TABLE test (i INTEGER, b BOOL, f FLOAT);');
$duckDB->query('INSERT INTO test VALUES (3, true, 1.1), (5, true, 1.2), (3, false, 1.1), (3, null,
1.2);');

$duckDB->query('SELECT * FROM test')->print();
```

As you probably guessed, `DuckDB::create()` creates a new connection to the specified database, or creates a new one if it doesn't exist yet and then establishes the connection.

After that, we can use the function `query` to perform the requests.

> Notice the difference between the static method `sql` and the non-static method `query`. While the first one always creates and destroys a new in-memory database, the second one uses a previously established connection and should be the preferred option in most cases.

In addition, the library also provides prepared statements for binding parameters to our query.

Prepared Statements

```
$duckDB = DuckDB::create();

$duckDB->query('CREATE TABLE test (i INTEGER, b BOOL, f FLOAT);');
$duckDB->query('INSERT INTO test VALUES (3, true, 1.1), (5, true, 1.2), (3, false, 1.1), (3, null,
1.2);');

$boolPreparedStatement = $duckDB->preparedStatement('SELECT * FROM test WHERE b = $1');
$boolPreparedStatement->bindParam(1, true);
$result = $boolPreparedStatement->execute();
$result->print();

$intPreparedStatement = $duckDB->preparedStatement('SELECT * FROM test WHERE i = ?');
$intPreparedStatement->bindParam(1, 3);
$result = $intPreparedStatement->execute();
$result->print();
```

Appenders

Appenders are the preferred method to load data in DuckDB. See Appender page for more information.

```
$duckDB = DuckDB::create();
$result = $duckDB->query('CREATE TABLE people (id INTEGER, name VARCHAR);');

$appender = $duckDB->appender('people');

for ($i = 0; $i < 100; ++$i) {
    $appender->append(rand(1, 100000));
    $appender->append('string-'.rand(1, 100));
    $appender->endRow();
}

$appender->flush();
```

DuckDB-Powerful

DuckDB provides some amazing features. For example, you can query remote files directly.

Let's use an aggregate function to calculate the average of a column for a Parquet remote file:

```
DuckDB::sql(
    'SELECT "Reporting Year", avg("Gas Produced, MCF") as "AVG Gas Produced"
    FROM "https://github.com/plotly/datasets/raw/refs/heads/master/oil-and-gas.parquet"
    WHERE "Reporting Year" BETWEEN 1985 AND 1990
    GROUP BY "Reporting Year";'
)->print();
```

```
---------------------------------------
| Reporting Year   | AVG Gas Produce |
---------------------------------------
| 1985             | 2461.4047344111 |
| 1986             | 6060.8575605681 |
| 1987             | 5047.5813074014 |
| 1988             | 4763.4090541633 |
| 1989             | 4175.2989758837 |
| 1990             | 3706.9404742437 |
---------------------------------------
```

Or summarize a remote CSV:

```
DuckDB::sql('SUMMARIZE TABLE "https://blobs.duckdb.org/data/Star_Trek-Season_1.csv";')->print();

```

Requirements

- Linux, macOS or Windows.
- x64 platform.
- PHP >= 8.3.
- ext-ffi.

Recommended

- ext-bcmath – Needed for big integers (> PHP_INT_MAX).
- ext-zend-opcache – For better performance.

Type Support

From version 1.2.0 on the library supports all DuckDB file types.

DuckDB Type	SQL Type	PHP Type
DUCKDB_TYPE_BOOLEAN	BOOLEAN	bool
DUCKDB_TYPE_TINYINT	TINYINT	int
DUCKDB_TYPE_SMALLINT	SMALLINT	int
DUCKDB_TYPE_INTEGER	INTEGER	int
DUCKDB_TYPE_BIGINT	BIGINT	int
DUCKDB_TYPE_UTINYINT	UTINYINT	int
DUCKDB_TYPE_USMALLINT	USMALLINT	int
DUCKDB_TYPE_UINTEGER	UINTEGER	int

DuckDB Type	SQL Type	PHP Type
DUCKDB_TYPE_UBIGINT	UBIGINT	Saturio\DuckDB\Type\Math\LongInteger
DUCKDB_TYPE_FLOAT	FLOAT	float
DUCKDB_TYPE_DOUBLE	DOUBLE	float
DUCKDB_TYPE_TIMESTAMP	TIMESTAMP	Saturio\DuckDB\Type\Timestamp
DUCKDB_TYPE_DATE	DATE	Saturio\DuckDB\Type\Date
DUCKDB_TYPE_TIME	TIME	Saturio\DuckDB\Type\Time
DUCKDB_TYPE_INTERVAL	INTERVAL	Saturio\DuckDB\Type\Interval
DUCKDB_TYPE_HUGEINT	HUGEINT	Saturio\DuckDB\Type\Math\LongInteger
DUCKDB_TYPE_UHUGEINT	UHUGEINT	Saturio\DuckDB\Type\Math\LongInteger
DUCKDB_TYPE_VARCHAR	VARCHAR	string
DUCKDB_TYPE_BLOB	BLOB	Saturio\DuckDB\Type\Blob
DUCKDB_TYPE_TIMESTAMP_S	TIMESTAMP_S	Saturio\DuckDB\Type\Timestamp
DUCKDB_TYPE_TIMESTAMP_MS	TIMESTAMP_MS	Saturio\DuckDB\Type\Timestamp
DUCKDB_TYPE_TIMESTAMP_NS	TIMESTAMP_NS	Saturio\DuckDB\Type\Timestamp
DUCKDB_TYPE_UUID	UUID	Saturio\DuckDB\Type\UUID
DUCKDB_TYPE_TIME_TZ	TIMETZ	Saturio\DuckDB\Type\Time
DUCKDB_TYPE_TIMESTAMP_TZ	TIMESTAMPTZ	Saturio\DuckDB\Type\Timestamp
DUCKDB_TYPE_DECIMAL	DECIMAL	float
DUCKDB_TYPE_ENUM	ENUM	string
DUCKDB_TYPE_LIST	LIST	array
DUCKDB_TYPE_STRUCT	STRUCT	array
DUCKDB_TYPE_ARRAY	ARRAY	array
DUCKDB_TYPE_MAP	MAP	array
DUCKDB_TYPE_UNION	UNION	mixed
DUCKDB_TYPE_BIT	BIT	string
DUCKDB_TYPE_BIGNUM	BIGNUM	string
DUCKDB_TYPE_SQLNULL	NULL	null

Swift Client

DuckDB has a Swift client. See the announcement post for details.

Instantiating DuckDB

DuckDB supports both in-memory and persistent databases. To work with an in-memory database, run:

```
let database = try Database(store: .inMemory)
```

To work with a persistent database, run:

```
let database = try Database(store: .file(at: "test.db"))
```

Queries can be issued through a database connection.

```
let connection = try database.connect()
```

DuckDB supports multiple connections per database.

Application Example

The rest of the page is based on the example of our announcement post, which uses raw data from NASA's Exoplanet Archive loaded directly into DuckDB.

Creating an Application-Specific Type

We first create an application-specific type that we'll use to house our database and connection and through which we'll eventually define our app-specific queries.

```
import DuckDB

final class ExoplanetStore {

  let database: Database
  let connection: Connection

  init(database: Database, connection: Connection) {
    self.database = database
    self.connection = connection
  }
}
```

Loading a CSV File

We load the data from NASA's Exoplanet Archive:

```
wget https://exoplanetarchive.ipac.caltech.edu/TAP/sync?query=select+pl_name+,+disc_
year+from+pscomppars&format=csv -O downloaded_exoplanets.csv
```

Once we have our CSV downloaded locally, we can use the following SQL command to load it as a new table to DuckDB:

```
CREATE TABLE exoplanets AS
    SELECT * FROM read_csv('downloaded_exoplanets.csv');
```

Let's package this up as a new asynchronous factory method on our `ExoplanetStore` type:

```
import DuckDB
import Foundation

final class ExoplanetStore {

  // Factory method to create and prepare a new ExoplanetStore
  static func create() async throws -> ExoplanetStore {

  // Create our database and connection as described above
    let database = try Database(store: .inMemory)
    let connection = try database.connect()

  // Download the CSV from the exoplanet archive
  let (csvFileURL, _) = try await URLSession.shared.download(
    from: URL(string: "https://exoplanetarchive.ipac.caltech.edu/TAP/sync?query=select+pl_name+,+disc_
year+from+pscomppars&format=csv")!)
```

```
  // Issue our first query to DuckDB
  try connection.execute("""
      CREATE TABLE exoplanets AS
          SELECT * FROM read_csv('\(csvFileURL.path)');
  """)

  // Create our pre-populated ExoplanetStore instance
    return ExoplanetStore(
    database: database,
      connection: connection
  )
  }

  // Let's make the initializer we defined previously
  // private. This prevents anyone accidentally instantiating
  // the store without having pre-loaded our Exoplanet CSV
  // into the database
  private init(database: Database, connection: Connection) {
  ...
  }
}
```

Querying the Database

The following example queries DuckDB from within Swift via an async function. This means the callee won't be blocked while the query is executing. We'll then cast the result columns to Swift native types using DuckDB's `ResultSet` `cast(to:)` family of methods, before finally wrapping them up in a `DataFrame` from the TabularData framework.

```
...

import TabularData

extension ExoplanetStore {

  // Retrieves the number of exoplanets discovered by year
  func groupedByDiscoveryYear() async throws -> DataFrame {

  // Issue the query we described above
    let result = try connection.query("""
      SELECT disc_year, count(disc_year) AS Count
        FROM exoplanets
        GROUP BY disc_year
        ORDER BY disc_year
      """)

    // Cast our DuckDB columns to their native Swift
    // equivalent types
    let discoveryYearColumn = result[0].cast(to: Int.self)
    let countColumn = result[1].cast(to: Int.self)

    // Use our DuckDB columns to instantiate TabularData
    // columns and populate a TabularData DataFrame
    return DataFrame(columns: [
      TabularData.Column(discoveryYearColumn).eraseToAnyColumn(),
      TabularData.Column(countColumn).eraseToAnyColumn(),
    ])
  }
}
```

Complete Project

For the complete example project, clone the DuckDB Swift repository and open up the runnable app project located in `Examples/SwiftUI/ExoplanetExplorer.xcodeproj`.

SQL

SQL Introduction

This page provides an overview of how to perform simple operations in SQL. This tutorial is only intended to give you an introduction and is in no way a complete tutorial on SQL. This tutorial is adapted from the PostgreSQL tutorial.

> DuckDB's SQL dialect closely follows the conventions of the PostgreSQL dialect. The few exceptions to this are listed on the PostgreSQL compatibility page.

In the examples that follow, we assume that you have installed the DuckDB Command Line Interface (CLI) shell. See the installation page for information on how to install the CLI.

> **Tip.** If you are looking for a comprehensive to SQL introduction, check the slide decks of the "Tabular Database Systems" course:
>
> - The Structured Query Language (SQL)
> - More SQL (Subqueries + Embedded SQL)
> - SQL: Grouping + Aggregation and Functional Dependencies

Concepts

DuckDB is a relational database management system (RDBMS). That means it is a system for managing data stored in relations. A relation is essentially a mathematical term for a table.

Each table is a named collection of rows. Each row of a given table has the same set of named columns, and each column is of a specific data type. Tables themselves are stored inside schemas, and a collection of schemas constitutes the entire database that you can access.

Creating a New Table

You can create a new table by specifying the table name, along with all column names and their types:

```
CREATE TABLE weather (
    city    VARCHAR,
    temp_lo INTEGER, -- minimum temperature on a day
    temp_hi INTEGER, -- maximum temperature on a day
    prcp    FLOAT,
    date    DATE
);
```

You can enter this into the shell with the line breaks. The command is not terminated until the semicolon.

White space (i.e., spaces, tabs and newlines) can be used freely in SQL commands. That means you can type the command aligned differently than above, or even all on one line. Two dash characters (`--`) introduce comments. Whatever follows them is ignored up to the end of the line. SQL is case-insensitive about keywords and identifiers. When returning identifiers, their original cases are preserved.

In the SQL command, we first specify the type of command that we want to perform: `CREATE TABLE`. After that follows the parameters for the command. First, the table name, `weather`, is given. Then the column names and column types follow.

`city VARCHAR` specifies that the table has a column called `city` that is of type VARCHAR. VARCHAR specifies a data type that can store text of arbitrary length. The temperature fields are stored in an `INTEGER` type, a type that stores integer numbers (i.e., whole numbers without a decimal point). `FLOAT` columns store single precision floating-point numbers (i.e., numbers with a decimal point). `DATE` stores a date (i.e., year, month, day combination). `DATE` only stores the specific day, not a time associated with that day.

DuckDB supports the standard SQL types `INTEGER`, `SMALLINT`, `FLOAT`, `DOUBLE`, `DECIMAL`, `CHAR(n)`, `VARCHAR(n)`, `DATE`, `TIME` and `TIMESTAMP`.

The second example will store cities and their associated geographical location:

```
CREATE TABLE cities (
    name VARCHAR,
    lat  DECIMAL,
    lon  DECIMAL
);
```

Finally, it should be mentioned that if you don't need a table any longer or want to recreate it differently you can remove it using the following command:

```
DROP TABLE <tablename>;
```

Populating a Table with Rows

The insert statement is used to populate a table with rows:

```
INSERT INTO weather
VALUES ('San Francisco', 46, 50, 0.25, '1994-11-27');
```

Constants that are not numeric values (e.g., text and dates) must be surrounded by single quotes (`''`), as in the example. Input dates for the date type must be formatted as `'YYYY-MM-DD'`.

We can insert into the `cities` table in the same manner.

```
INSERT INTO cities
VALUES ('San Francisco', -194.0, 53.0);
```

The syntax used so far requires you to remember the order of the columns. An alternative syntax allows you to list the columns explicitly:

```
INSERT INTO weather (city, temp_lo, temp_hi, prcp, date)
VALUES ('San Francisco', 43, 57, 0.0, '1994-11-29');
```

You can list the columns in a different order if you wish or even omit some columns, e.g., if the `prcp` is unknown:

```
INSERT INTO weather (date, city, temp_hi, temp_lo)
VALUES ('1994-11-29', 'Hayward', 54, 37);
```

> **Tip.** Many developers consider explicitly listing the columns better style than relying on the order implicitly.

Please enter all the commands shown above so you have some data to work with in the following sections.

Alternatively, you can use the `COPY` statement. This is faster for large amounts of data because the `COPY` command is optimized for bulk loading while allowing less flexibility than `INSERT`. An example with `weather.csv` would be:

```
COPY weather
FROM 'weather.csv';
```

Where the file name for the source file must be available on the machine running the process. There are many other ways of loading data into DuckDB, see the corresponding documentation section for more information.

Querying a Table

To retrieve data from a table, the table is queried. A SQL `SELECT` statement is used to do this. The statement is divided into a select list (the part that lists the columns to be returned), a table list (the part that lists the tables from which to retrieve the data), and an optional qualification (the part that specifies any restrictions). For example, to retrieve all the rows of table weather, type:

```
SELECT *
FROM weather;
```

Here * is a shorthand for “all columns”. So the same result would be had with:

```
SELECT city, temp_lo, temp_hi, prcp, date
FROM weather;
```

The output should be:

city	temp_lo	temp_hi	prcp	date
San Francisco	46	50	0.25	1994-11-27
San Francisco	43	57	0.0	1994-11-29
Hayward	37	54	NULL	1994-11-29

You can write expressions, not just simple column references, in the select list. For example, you can do:

```
SELECT city, (temp_hi + temp_lo) / 2 AS temp_avg, date
FROM weather;
```

This should give:

city	temp_avg	date
San Francisco	48.0	1994-11-27
San Francisco	50.0	1994-11-29
Hayward	45.5	1994-11-29

Notice how the AS clause is used to relabel the output column. (The AS clause is optional.)

A query can be “qualified” by adding a WHERE clause that specifies which rows are wanted. The WHERE clause contains a Boolean (truth value) expression, and only rows for which the Boolean expression is true are returned. The usual Boolean operators (AND, OR and NOT) are allowed in the qualification. For example, the following retrieves the weather of San Francisco on rainy days:

```
SELECT *
FROM weather
WHERE city = 'San Francisco'
  AND prcp > 0.0;
```

Result:

city	temp_lo	temp_hi	prcp	date
San Francisco	46	50	0.25	1994-11-27

You can request that the results of a query be returned in sorted order:

```
SELECT *
FROM weather
ORDER BY city;
```

city	temp_lo	temp_hi	prcp	date
Hayward	37	54	NULL	1994-11-29
San Francisco	43	57	0.0	1994-11-29
San Francisco	46	50	0.25	1994-11-27

In this example, the sort order isn't fully specified, and so you might get the San Francisco rows in either order. But you'd always get the results shown above if you do:

```
SELECT *
FROM weather
ORDER BY city, temp_lo;
```

You can request that duplicate rows be removed from the result of a query:

```
SELECT DISTINCT city
FROM weather;
```

city
San Francisco
Hayward

Here again, the result row ordering might vary. You can ensure consistent results by using `DISTINCT` and `ORDER BY` together:

```
SELECT DISTINCT city
FROM weather
ORDER BY city;
```

Joins between Tables

Thus far, our queries have only accessed one table at a time. Queries can access multiple tables at once, or access the same table in such a way that multiple rows of the table are being processed at the same time. A query that accesses multiple rows of the same or different tables at one time is called a join query. As an example, say you wish to list all the weather records together with the location of the associated city. To do that, we need to compare the city column of each row of the `weather` table with the name column of all rows in the `cities` table, and select the pairs of rows where these values match.

This would be accomplished by the following query:

```
SELECT *
FROM weather, cities
WHERE city = name;
```

city	temp_lo	temp_hi	prcp	date	name	lat	lon
San Francisco	46	50	0.25	1994-11-27	San Francisco	-194.000	53.000
San Francisco	43	57	0.0	1994-11-29	San Francisco	-194.000	53.000

Observe two things about the result set:

- There is no result row for the city of Hayward. This is because there is no matching entry in the `cities` table for Hayward, so the join ignores the unmatched rows in the `weather` table. We will see shortly how this can be fixed.

- There are two columns containing the city name. This is correct because the lists of columns from the `weather` and `cities` tables are concatenated. In practice this is undesirable, though, so you will probably want to list the output columns explicitly rather than using `*`:

```
SELECT city, temp_lo, temp_hi, prcp, date, lon, lat
FROM weather, cities
WHERE city = name;
```

city	temp_lo	temp_hi	prcp	date	lon	lat
San Francisco	46	50	0.25	1994-11-27	53.000	-194.000
San Francisco	43	57	0.0	1994-11-29	53.000	-194.000

Since the columns all had different names, the parser automatically found which table they belong to. If there were duplicate column names in the two tables you'd need to qualify the column names to show which one you meant, as in:

```
SELECT weather.city, weather.temp_lo, weather.temp_hi,
       weather.prcp, weather.date, cities.lon, cities.lat
FROM weather, cities
WHERE cities.name = weather.city;
```

It is widely considered good style to qualify all column names in a join query, so that the query won't fail if a duplicate column name is later added to one of the tables.

Join queries of the kind seen thus far can also be written in this alternative form:

```
SELECT *
FROM weather
INNER JOIN cities ON weather.city = cities.name;
```

This syntax is not as commonly used as the one above, but we show it here to help you understand the following topics.

Now we will figure out how we can get the Hayward records back in. What we want the query to do is to scan the `weather` table and for each row to find the matching cities row(s). If no matching row is found we want some “empty values” to be substituted for the `cities` table's columns. This kind of query is called an outer join. (The joins we have seen so far are inner joins.) The command looks like this:

```
SELECT *
FROM weather
LEFT OUTER JOIN cities ON weather.city = cities.name;
```

city	temp_lo	temp_hi	prcp	date	name	lat	lon
San Francisco	46	50	0.25	1994-11-27	San Francisco	-194.000	53.000
San Francisco	43	57	0.0	1994-11-29	San Francisco	-194.000	53.000
Hayward	37	54	NULL	1994-11-29	NULL	NULL	NULL

This query is called a left outer join because the table mentioned on the left of the join operator will have each of its rows in the output at least once, whereas the table on the right will only have those rows output that match some row of the left table. When outputting a left-table row for which there is no right-table match, empty (null) values are substituted for the right-table columns.

Aggregate Functions

Like most other relational database products, DuckDB supports aggregate functions. An aggregate function computes a single result from multiple input rows. For example, there are aggregates to compute the `count`, `sum`, `avg` (average), `max` (maximum) and `min` (minimum) over a set of rows.

As an example, we can find the highest low-temperature reading anywhere with:

```
SELECT max(temp_lo)
FROM weather;
```

max(temp_lo)
46

If we wanted to know what city (or cities) that reading occurred in, we might try:

```
SELECT city
FROM weather
WHERE temp_lo = max(temp_lo);
```

But this will not work since the aggregate max cannot be used in the WHERE clause:

```
Binder Error:
WHERE clause cannot contain aggregates!
```

This restriction exists because the WHERE clause determines which rows will be included in the aggregate calculation; so obviously it has to be evaluated before aggregate functions are computed. However, as is often the case the query can be restated to accomplish the desired result, here by using a subquery:

```
SELECT city
FROM weather
WHERE temp_lo = (SELECT max(temp_lo) FROM weather);
```

city
San Francisco

This is OK because the subquery is an independent computation that computes its own aggregate separately from what is happening in the outer query.

Aggregates are also very useful in combination with GROUP BY clauses. For example, we can get the maximum low temperature observed in each city with:

```
SELECT city, max(temp_lo)
FROM weather
GROUP BY city;
```

city	max(temp_lo)
San Francisco	46
Hayward	37

Which gives us one output row per city. Each aggregate result is computed over the table rows matching that city. We can filter these grouped rows using HAVING:

```
SELECT city, max(temp_lo)
FROM weather
GROUP BY city
HAVING max(temp_lo) < 40;
```

city	max(temp_lo)
Hayward	37

which gives us the same results for only the cities that have all `temp_lo` values below 40. Finally, if we only care about cities whose names begin with S, we can use the `LIKE` operator:

```
SELECT city, max(temp_lo)
FROM weather
WHERE city LIKE 'S%'            -- (1)
GROUP BY city
HAVING max(temp_lo) < 40;
```

More information about the `LIKE` operator can be found in the pattern matching page.

It is important to understand the interaction between aggregates and SQL's `WHERE` and `HAVING` clauses. The fundamental difference between `WHERE` and `HAVING` is this: `WHERE` selects input rows before groups and aggregates are computed (thus, it controls which rows go into the aggregate computation), whereas `HAVING` selects group rows after groups and aggregates are computed. Thus, the `WHERE` clause must not contain aggregate functions; it makes no sense to try to use an aggregate to determine which rows will be inputs to the aggregates. On the other hand, the `HAVING` clause always contains aggregate functions.

In the previous example, we can apply the city name restriction in `WHERE`, since it needs no aggregate. This is more efficient than adding the restriction to `HAVING`, because we avoid doing the grouping and aggregate calculations for all rows that fail the `WHERE` check.

Updates

You can update existing rows using the `UPDATE` command. Suppose you discover the temperature readings are all off by 2 degrees after November 28. You can correct the data as follows:

```
UPDATE weather
SET temp_hi = temp_hi - 2,  temp_lo = temp_lo - 2
WHERE date > '1994-11-28';
```

Look at the new state of the data:

```
SELECT *
FROM weather;
```

city	temp_lo	temp_hi	prcp	date
San Francisco	46	50	0.25	1994-11-27
San Francisco	41	55	0.0	1994-11-29
Hayward	35	52	NULL	1994-11-29

Deletions

Rows can be removed from a table using the `DELETE` command. Suppose you are no longer interested in the weather of Hayward. Then you can do the following to delete those rows from the table:

```
DELETE FROM weather
WHERE city = 'Hayward';
```

All weather records belonging to Hayward are removed.

```
SELECT *
FROM weather;
```

city	temp_lo	temp_hi	prcp	date
San Francisco	46	50	0.25	1994-11-27
San Francisco	41	55	0.0	1994-11-29

One should be cautious when issuing statements of the following form:

```
DELETE FROM <table_name>;
```

> **Warning.** Without a qualification, DELETE will remove all rows from the given table, leaving it empty. The system will not request confirmation before doing this.

Statements

Statements Overview

ANALYZE Statement

The ANALYZE statement recomputes the statistics on DuckDB's tables.

Usage

The statistics recomputed by the ANALYZE statement are only used for join order optimization. It is therefore recommended to recompute these statistics for improved join orders, especially after performing large updates (inserts and/or deletes).

To recompute the statistics, run:

```
ANALYZE;
```

ALTER TABLE Statement

The ALTER TABLE statement changes the schema of an existing table in the catalog.

Examples

```
CREATE TABLE integers (i INTEGER, j INTEGER);
```

Add a new column with name k to the table integers, it will be filled with the default value NULL:

```
ALTER TABLE integers
ADD COLUMN k INTEGER;
```

Add a new column with name l to the table integers, it will be filled with the default value 10:

```
ALTER TABLE integers
ADD COLUMN l INTEGER DEFAULT 10;
```

Drop the column k from the table integers:

```
ALTER TABLE integers
DROP k;
```

Change the type of the column i to the type VARCHAR using a standard cast:

```
ALTER TABLE integers
ALTER i TYPE VARCHAR;
```

Change the type of the column i to the type VARCHAR, using the specified expression to convert the data for each row:

```
ALTER TABLE integers
ALTER i SET DATA TYPE VARCHAR USING concat(i, '_', j);
```

Set the default value of a column:

```
ALTER TABLE integers
ALTER COLUMN i SET DEFAULT 10;
```

Drop the default value of a column:

```
ALTER TABLE integers
ALTER COLUMN i DROP DEFAULT;
```

Make a column not nullable:

```
ALTER TABLE integers
ALTER COLUMN i SET NOT NULL;
```

Drop the not-NULL constraint:

```
ALTER TABLE integers
ALTER COLUMN i DROP NOT NULL;
```

Rename a table:

```
ALTER TABLE integers
RENAME TO integers_old;
```

Rename a column of a table:

```
ALTER TABLE integers
RENAME i TO ii;
```

Add a primary key to a column of a table:

```
ALTER TABLE integers
ADD PRIMARY KEY (i);
```

Syntax

`ALTER TABLE` changes the schema of an existing table. All the changes made by `ALTER TABLE` fully respect the transactional semantics, i.e., they will not be visible to other transactions until committed, and can be fully reverted through a rollback.

`RENAME TABLE`

Rename a table:

```
ALTER TABLE integers
RENAME TO integers_old;
```

The `RENAME TO` clause renames an entire table, changing its name in the schema. Note that any views that rely on the table are **not** automatically updated.

`RENAME COLUMN`

To rename a column of a table, use the `RENAME` or `RENAME COLUMN` clauses:

```
ALTER TABLE integers
RENAME COLUMN i TO j;
```

```
ALTER TABLE integers
RENAME i TO j;
```

The `RENAME [COLUMN]` clause renames a single column within a table. Any constraints that rely on this name (e.g., `CHECK` constraints) are automatically updated. However, note that any views that rely on this column name are **not** automatically updated.

ADD COLUMN

To add a column of a table, use the ADD or ADD COLUMN clauses.

E.g., to add a new column with name k to the table `integers`, it will be filled with the default value NULL:

```
ALTER TABLE integers
ADD COLUMN k INTEGER;
```

Or:

```
ALTER TABLE integers
ADD k INTEGER;
```

Add a new column with name `l` to the table integers, it will be filled with the default value 10:

```
ALTER TABLE integers
ADD COLUMN l INTEGER DEFAULT 10;
```

The ADD [COLUMN] clause can be used to add a new column of a specified type to a table. The new column will be filled with the specified default value, or NULL if none is specified.

DROP COLUMN

To drop a column of a table, use the DROP or DROP COLUMN clause:

E.g., to drop the column k from the table `integers`:

```
ALTER TABLE integers
DROP COLUMN k;
```

Or:

```
ALTER TABLE integers
DROP k;
```

The DROP [COLUMN] clause can be used to remove a column from a table. Note that columns can only be removed if they do not have any indexes that rely on them. This includes any indexes created as part of a PRIMARY KEY or UNIQUE constraint. Columns that are part of multi-column check constraints cannot be dropped either. If you attempt to drop a column with an index on it, DuckDB will return the following error message:

```
Dependency Error:
Cannot alter entry "..." because there are entries that depend on it.
```

[SET [DATA]] TYPE

Change the type of the column `i` to the type VARCHAR using a standard cast:

```
ALTER TABLE integers
ALTER i TYPE VARCHAR;
```

> Instead of ALTER <column_name> TYPE <type>{:.language-sql .highlight}, you can also use the equivalent ALTER <column_name> SET TYPE <type>{:.language-sql .highlight} and the ALTER <column_name> SET DATA TYPE <type>{:.language-sql .highlight} clauses.

Change the type of the column `i` to the type VARCHAR, using the specified expression to convert the data for each row:

```
ALTER TABLE integers
ALTER i SET DATA TYPE VARCHAR USING concat(i, '_', j);
```

The [SET [DATA]] TYPE clause changes the type of a column in a table. Any data present in the column is converted according to the provided expression in the USING clause, or, if the USING clause is absent, cast to the new data type. Note that columns can only have their type changed if they do not have any indexes that rely on them and are not part of any CHECK constraints.

Handling Structs

There are two options to change the sub-schema of a STRUCT-typed column.

`ALTER TABLE` with `struct_insert` You can use `ALTER TABLE` with the `struct_insert` function. For example:

```
CREATE TABLE tbl (col STRUCT(i INTEGER));
ALTER TABLE tbl
ALTER col TYPE USING struct_insert(col, a := 42, b := NULL::VARCHAR);
```

`ALTER TABLE` with `ADD COLUMN` / `DROP COLUMN` / `RENAME COLUMN` Starting with DuckDB v1.3.0, `ALTER TABLE` supports the `ADD COLUMN`, `DROP COLUMN` and `RENAME COLUMN` clauses to update the sub-schema of a STRUCT.

`SET` / `DROP DEFAULT`

Set the default value of a column:

```
ALTER TABLE integers
ALTER COLUMN i SET DEFAULT 10;
```

Drop the default value of a column:

```
ALTER TABLE integers
ALTER COLUMN i DROP DEFAULT;
```

The `SET`/`DROP DEFAULT` clause modifies the `DEFAULT` value of an existing column. Note that this does not modify any existing data in the column. Dropping the default is equivalent to setting the default value to NULL.

> **Warning.** At the moment DuckDB will not allow you to alter a table if there are any dependencies. That means that if you have an index on a column you will first need to drop the index, alter the table, and then recreate the index. Otherwise, you will get a `Dependency Error`.

`ADD PRIMARY KEY`

Add a primary key to a column of a table:

```
ALTER TABLE integers
ADD PRIMARY KEY (i);
```

Add a primary key to multiple columns of a table:

```
ALTER TABLE integers
ADD PRIMARY KEY (i, j);
```

`SET` / `RESET` (Table Options)

> This feature was introduced in DuckDB v1.5.

Modify table options after table creation.

Set table options:

```
ALTER TABLE my_table
SET ('option_name' = 'value');
```

Reset table options to their defaults:

```
ALTER TABLE my_table
RESET ('option_name');
```

The SET clause assigns values to table options as key-value pairs. The RESET clause removes options or restores them to their default values, depending on the catalog implementation.

Multiple options can be set or reset in a single statement:

```
ALTER TABLE my_table
SET ('option1' = 'value1', 'option2' = 'value2');

ALTER TABLE my_table
RESET ('option1', 'option2');
```

ADD / DROP CONSTRAINT

> ADD CONSTRAINT and DROP CONSTRAINT clauses are not yet supported in DuckDB.

Limitations

ALTER COLUMN fails if values of conflicting types have occurred in the table at any point, even if they have been deleted:

```
CREATE TABLE tbl (col VARCHAR);

INSERT INTO tbl
VALUES ('asdf'), ('42');

DELETE FROM tbl
WHERE col = 'asdf';

ALTER TABLE tbl
ALTER COLUMN col TYPE INTEGER;
```

```
Conversion Error:
Could not convert string 'asdf' to INT32
```

Currently, this is expected behavior. As a workaround, you can create a copy of the table:

```
CREATE OR REPLACE TABLE tbl AS FROM tbl;
```

ALTER VIEW Statement

The ALTER VIEW statement changes the schema of an existing view in the catalog.

Examples

Rename a view:

```
ALTER VIEW view1 RENAME TO view2;
```

ALTER VIEW changes the schema of an existing view. All the changes made by ALTER VIEW fully respect the transactional semantics, i.e., they will not be visible to other transactions until committed, and can be fully reverted through a rollback. Note that other views that rely on the view are **not** automatically updated.

ATTACH and DETACH Statements

DuckDB allows attaching to and detaching from database files.

Examples

Attach the database `file.db` with the alias inferred from the name (`file`):

```
ATTACH 'file.db';
```

Attach the database `file.db` with an explicit alias (`file_db`):

```
ATTACH 'file.db' AS file_db;
```

Attach the database `file.db` in read only mode:

```
ATTACH 'file.db' (READ_ONLY);
```

Attach the database `file.db` with a block size of 16 kB:

```
ATTACH 'file.db' (BLOCK_SIZE 16_384);
```

Attach the database `file.db` with a row group size of 2048 rows:

```
ATTACH 'file.db' (ROW_GROUP_SIZE 2048);
```

Attach the database `file.db` with WAL writes disabled for improved performance:

```
ATTACH 'file.db' (RECOVERY_MODE no_wal_writes);
```

Attach a SQLite database for reading and writing (see the `sqlite` extension for more information):

```
ATTACH 'sqlite_file.db' AS sqlite_db (TYPE sqlite);
```

Attach the database `file.db` if inferred database alias `file` does not yet exist:

```
ATTACH IF NOT EXISTS 'file.db';
```

Attach the database `file.db` if explicit database alias `file_db` does not yet exist:

```
ATTACH IF NOT EXISTS 'file.db' AS file_db;
```

Attach the database `file2.db` as alias `file_db` detaching and replacing the existing alias if it exists:

```
ATTACH OR REPLACE 'file2.db' AS file_db;
```

Create a table in the attached database with alias `file`:

```
CREATE TABLE file.new_table (i INTEGER);
```

Detach the database with alias `file`:

```
DETACH file;
```

Show a list of all attached databases:

```
SHOW DATABASES;
```

Change the default database that is used to the database `file`:

```
USE file;
```

ATTACH

The ATTACH statement adds a new database file to the catalog that can be read from and written to. Note that attachment definitions are not persisted between sessions: when a new session is launched, you have to re-attach to all databases.

ATTACH Syntax

ATTACH allows DuckDB to operate on multiple database files, and allows for transfer of data between different database files.

ATTACH supports HTTP and S3 endpoints. For these, it creates a read-only connection by default. Therefore, the following two commands are equivalent:

```
ATTACH 'https://blobs.duckdb.org/databases/stations.duckdb' AS stations_db;
ATTACH 'https://blobs.duckdb.org/databases/stations.duckdb' AS stations_db (READ_ONLY);
```

Similarly, the following two commands connecting to S3 are equivalent:

```
ATTACH 's3://<blobs-duckdb>/databases/stations.duckdb' AS stations_db;
ATTACH 's3://<blobs-duckdb>/databases/stations.duckdb' AS stations_db (READ_ONLY);
```

Explicit Storage Versions

DuckDB v1.2.0 introduced the `STORAGE_VERSION` option, which allows explicitly specifying the storage version. Using this, you can opt-in to newer forwards-incompatible features:

```
ATTACH 'file.db' (STORAGE_VERSION 'v1.2.0');
```

This setting specifies the minimum DuckDB version that should be able to read the database file. When database files are written with this option, the resulting files cannot be opened by older DuckDB versions than the specified version. They can be read by the specified version and all newer versions of DuckDB.

To initialize a database with the latest storage version, use:

```
ATTACH 'file.db' (STORAGE_VERSION 'latest');
```

For more details, see the "Storage" page.

Database Encryption

DuckDB supports database encryption. By default, it uses AES encryption with a key length of 256 bits using the recommended GCM mode. The encryption covers the main database file, the write-ahead-log (WAL) file, and even temporary files. To attach to an encrypted database, use the `ATTACH` statement with an `ENCRYPTION_KEY`.

```
ATTACH 'encrypted.db' AS enc_db (ENCRYPTION_KEY 'quack_quack');
```

To encrypt data, DuckDB can use either the built-in `mbedtls` library or the OpenSSL library from the `httpfs` extension. Note that the OpenSSL versions are much faster due to hardware acceleration, so make sure to load the `httpfs` for good encryption performance:

```
LOAD httpfs;
ATTACH 'encrypted.db' AS enc_db (ENCRYPTION_KEY 'quack_quack'); -- will be faster thanks to httpfs
```

To change the AES mode to CBC or CTR, use the `ENCRYPTION_CIPHER` option:

```
ATTACH 'encrypted.db' AS enc_db (ENCRYPTION_KEY 'quack_quack', ENCRYPTION_CIPHER 'CBC');
ATTACH 'encrypted.db' AS enc_db (ENCRYPTION_KEY 'quack_quack', ENCRYPTION_CIPHER 'CTR');
```

Database encryption implies using storage version 1.4.0 or later.

> DuckDB's encryption does not yet meet the official NIST requirements. Please follow issue #20162 "Store and verify tag for canary encryption" to track our progress towards NIST-compliance.

Options

Zero or more copy options may be provided within parentheses following the ATTACH statement. Parameter values can be passed in with or without wrapping in single quotes. Arbitrary expressions may be used for parameter values.

Name	Description	Type	Default value
READ_ONLY	Attach the database in read-only mode. Use READ_WRITE (the default) to attach in read-write mode.	BOOLEAN	false
COMPRESS	Whether the database is compressed. Only applicable for in-memory databases.	VARCHAR	false
TYPE	The file type (DUCKDB or SQLITE), or deduced from the input string literal (MySQL, PostgreSQL).	VARCHAR	DUCKDB
DEFAULT_TABLE	The table that is queried when the attached database is referenced directly by its catalog name (e.g., FROM <db>).	VARCHAR	-
BLOCK_SIZE	The block size of a new database file. Must be a power of two and within [16384, 262144]. Cannot be set for existing files.	UBIGINT	262144
ROW_GROUP_SIZE	The row group size of a new database file.	UBIGINT	122880
STORAGE_VERSION	The version of the storage used.	VARCHAR	v1.0.0
ENCRYPTION_KEY	The encryption key used for encrypting the database.	VARCHAR	-
ENCRYPTION_CIPHER	The encryption cipher used for encrypting the database (CBC, CTR or GCM).	VARCHAR	-
RECOVERY_MODE	Recovery mode for the database. no_wal_writes disables WAL writes, improving performance at the cost of crash recovery.	VARCHAR	-

DETACH

The DETACH statement allows previously attached database files to be closed and detached, releasing any locks held on the database file.

Note that it is not possible to detach from the default database: if you would like to do so, issue the USE statement to change the default database to another one. For example, if you are connected to a persistent database, you may change to an in-memory database by issuing:

```
ATTACH ':memory:' AS memory_db;
USE memory_db;
```

> **Warning.** Closing the connection, e.g., invoking the close() function in Python, does not release the locks held on the database files as the file handles are held by the main DuckDB instance (in Python's case, the duckdb module).

DETACH Syntax

Name Qualification

The fully qualified name of catalog objects contains the *catalog*, the *schema* and the *name* of the object. For example:

Attach the database new_db:

```
ATTACH 'new_db.db';
```

Create the schema `my_schema` in the database `new_db`:

```
CREATE SCHEMA new_db.my_schema;
```

Create the table `my_table` in the schema `my_schema`:

```
CREATE TABLE new_db.my_schema.my_table (col INTEGER);
```

Refer to the column `col` inside the table `my_table`:

```
SELECT new_db.my_schema.my_table.col FROM new_db.my_schema.my_table;
```

Note that often the fully qualified name is not required. When a name is not fully qualified, the system looks for which entries to reference using the *catalog search path*. The default catalog search path includes the system catalog, the temporary catalog and the initially attached database together with the `main` schema.

Also note the rules on identifiers and database names in particular.

Default Database and Schema

When a table is created without any qualifications, the table is created in the default schema of the default database. The default database is the database that is launched when the system is created – and the default schema is `main`.

Create the table `my_table` in the default database:

```
CREATE TABLE my_table (col INTEGER);
```

Changing the Default Database and Schema

The default database and schema can be changed using the USE command.

Set the default database schema to `new_db.main`:

```
USE new_db;
```

Set the default database schema to `new_db.my_schema`:

```
USE new_db.my_schema;
```

Resolving Conflicts

When providing only a single qualification, the system can interpret this as *either* a catalog *or* a schema, as long as there are no conflicts. For example:

```
ATTACH 'new_db.db';
CREATE SCHEMA my_schema;
```

Creates the table `new_db.main.tbl`:

```
CREATE TABLE new_db.tbl (i INTEGER);
```

Creates the table `default_db.my_schema.tbl`:

```
CREATE TABLE my_schema.tbl (i INTEGER);
```

If we create a conflict (i.e., we have both a schema and a catalog with the same name) the system requests that a fully qualified path is used instead:

```
CREATE SCHEMA new_db;
CREATE TABLE new_db.tbl (i INTEGER);
```

```
Binder Error:
Ambiguous reference to catalog or schema "new_db" - use a fully qualified path like "memory.new_db"
```

Changing the Catalog Search Path

The catalog search path can be adjusted by setting the `search_path` configuration option, which uses a comma-separated list of values that will be on the search path. The following example demonstrates searching in two databases:

```
ATTACH ':memory:' AS db1;
ATTACH ':memory:' AS db2;
CREATE table db1.tbl1 (i INTEGER);
CREATE table db2.tbl2 (j INTEGER);
```

Reference the tables using their fully qualified name:

```
SELECT * FROM db1.tbl1;
SELECT * FROM db2.tbl2;
```

Or set the search path and reference the tables using their name:

```
SET search_path = 'db1,db2';
SELECT * FROM tbl1;
SELECT * FROM tbl2;
```

Transactional Semantics

When running queries on multiple databases, the system opens separate transactions per database. The transactions are started *lazily* by default – when a given database is referenced for the first time in a query, a transaction for that database will be started. `SET immediate_transaction_mode = true` can be toggled to change this behavior to eagerly start transactions in all attached databases instead.

While multiple transactions can be active at a time – the system only supports *writing* to a single attached database in a single transaction. If you try to write to multiple attached databases in a single transaction the following error will be thrown:

```
Attempting to write to database "db2" in a transaction that has already modified database "db1" –
a single transaction can only write to a single attached database.
```

The reason for this restriction is that the system does not maintain atomicity for transactions across attached databases. Transactions are only atomic *within* each database file. By restricting the global transaction to write to only a single database file the atomicity guarantees are maintained.

CALL Statement

The `CALL` statement invokes the given table function and returns the results.

> Thanks to the FROM-first syntax and the fact that procedures in DuckDB are implemented as table functions, you can use `FROM` instead of `CALL`.

Examples

Invoke the 'duckdb_functions' table function:

```
CALL duckdb_functions();
```

Invoke the 'pragma_table_info' table function:

```
CALL pragma_table_info('pg_am');
```

Select only the functions where the name starts with `ST_`:

```
SELECT function_name, parameters, parameter_types, return_type
FROM duckdb_functions()
WHERE function_name LIKE 'ST_%';
```

Syntax

CHECKPOINT Statement

The CHECKPOINT statement synchronizes data in the write-ahead log (WAL) to the database data file.

Examples

Synchronize data in the default database:

```
CHECKPOINT;
```

Synchronize data in the specified database:

```
CHECKPOINT file_db;
```

Synchronize data and prevent new transactions from starting:

```
FORCE CHECKPOINT;
```

> In earlier DuckDB versions, FORCE CHECKPOINT aborted any in-progress transactions. From v1.4, it waits until it can grab the checkpoint lock.

Checkpointing In-Memory Tables

Starting with v1.4.0, in-memory tables support checkpointing. This has two key benefits:

- In-memory tables also support compression. This is disabled by default – you can turn it on using:

  ```
  ATTACH ':memory:' AS memory_compressed (COMPRESS);
  USE memory_compressed;
  ```

- Checkpointing triggers vacuuming deleted rows, allowing space to be reclaimed after deletes/truncation.

Syntax

Checkpoint operations happen automatically based on the WAL size (see Configuration). This statement is for manual checkpoint actions.

Behavior

The default CHECKPOINT command will fail if there are any running transactions. Including FORCE will wait until it can grab the checkpoint lock and then execute the checkpoint operation. In DuckDB versions before v1.4, FORCE CHECKPOINT instead aborted any in-progress transactions.

Also see the related PRAGMA option for further behavior modification.

Reclaiming Space

When performing a checkpoint (automatic or otherwise), the space occupied by deleted rows is partially reclaimed. Note that this does not remove all deleted rows, but rather merges row groups that have a significant amount of deletes together. In the current implementation this requires ~25% of rows to be deleted in adjacent row groups.

Since v1.4.0, checkpointing also applies to in-memory databases (see Checkpointing In-Memory Tables), where it likewise vacuums deleted rows and reclaims space.

> **Warning.** The VACUUM statement does *not* trigger vacuuming deletes and hence does not reclaim space.

COMMENT ON Statement

The `COMMENT ON` statement allows adding metadata to catalog entries (tables, columns, etc.). It follows the PostgreSQL syntax.

Examples

Create a comment on a `TABLE`:

```
COMMENT ON TABLE test_table IS 'very nice table';
```

Create a comment on a `COLUMN`:

```
COMMENT ON COLUMN test_table.test_table_column IS 'very nice column';
```

Create a comment on a `VIEW`:

```
COMMENT ON VIEW test_view IS 'very nice view';
```

Create a comment on an `INDEX`:

```
COMMENT ON INDEX test_index IS 'very nice index';
```

Create a comment on a `SEQUENCE`:

```
COMMENT ON SEQUENCE test_sequence IS 'very nice sequence';
```

Create a comment on a `TYPE`:

```
COMMENT ON TYPE test_type IS 'very nice type';
```

Create a comment on a `MACRO`:

```
COMMENT ON MACRO test_macro IS 'very nice macro';
```

Create a comment on a `MACRO TABLE`:

```
COMMENT ON MACRO TABLE test_table_macro IS 'very nice table macro';
```

To unset a comment, set it to `NULL`, e.g.:

```
COMMENT ON TABLE test_table IS NULL;
```

Reading Comments

Comments can be read by querying the `comment` column of the respective metadata functions:

List comments on `TABLE`s:

```
SELECT comment FROM duckdb_tables();
```

List comments on `COLUMN`s:

```
SELECT comment FROM duckdb_columns();
```

List comments on `VIEW`s:

```
SELECT comment FROM duckdb_views();
```

List comments on `INDEX`s:

```
SELECT comment FROM duckdb_indexes();
```

List comments on SEQUENCEs:

```
SELECT comment FROM duckdb_sequences();
```

List comments on TYPEs:

```
SELECT comment FROM duckdb_types();
```

List comments on MACROs:

```
SELECT comment FROM duckdb_functions();
```

List comments on MACRO TABLEs:

```
SELECT comment FROM duckdb_functions();
```

Limitations

The COMMENT ON statement currently has the following limitations:

- It is not possible to comment on schemas or databases.
- It is not possible to comment on things that have a dependency (e.g., a table with an index).

Syntax

COPY Statement

Examples

Read a CSV file into the `lineitem` table, using auto-detected CSV options:

```
COPY lineitem FROM 'lineitem.csv';
```

Read a CSV file into the `lineitem` table, using manually specified CSV options:

```
COPY lineitem FROM 'lineitem.csv' (DELIMITER '|');
```

Read a Parquet file into the `lineitem` table:

```
COPY lineitem FROM 'lineitem.pq' (FORMAT parquet);
```

Read a JSON file into the `lineitem` table, using auto-detected options:

```
COPY lineitem FROM 'lineitem.json' (FORMAT json, AUTO_DETECT true);
```

Read a CSV file into the `lineitem` table, using double quotes:

```
COPY lineitem FROM "lineitem.csv";
```

Read a CSV file into the `lineitem` table, omitting quotes:

```
COPY lineitem FROM lineitem.csv;
```

Write a table to a CSV file:

```
COPY lineitem TO 'lineitem.csv' (FORMAT csv, DELIMITER '|', HEADER);
```

Write a table to a CSV file, using double quotes:

```
COPY lineitem TO "lineitem.csv";
```

Write a table to a CSV file, omitting quotes:

```
COPY lineitem TO lineitem.csv;
```

Write the result of a query to a Parquet file:

```
COPY (SELECT l_orderkey, l_partkey FROM lineitem) TO 'lineitem.parquet' (COMPRESSION zstd);
```

Copy the entire content of database db1 to database db2:

```
COPY FROM DATABASE db1 TO db2;
```

Copy only the schema (catalog elements) but not any data:

```
COPY FROM DATABASE db1 TO db2 (SCHEMA);
```

Overview

COPY moves data between DuckDB and external files. `COPY ... FROM` imports data into DuckDB from an external file. `COPY ... TO` writes data from DuckDB to an external file. The COPY command can be used for CSV, PARQUET and JSON files.

`COPY ... FROM`

`COPY ... FROM` imports data from an external file into an existing table. The data is appended to whatever data is in the table already. The amount of columns inside the file must match the amount of columns in the table `tbl`, and the contents of the columns must be convertible to the column types of the table. In case this is not possible, an error will be thrown.

If a list of columns is specified, COPY will only copy the data in the specified columns from the file. If there are any columns in the table that are not in the column list, `COPY ... FROM` will insert the default values for those columns.

Copy the contents of a comma-separated file `test.csv` without a header into the table `test`:

```
COPY test FROM 'test.csv';
```

Copy the contents of a comma-separated file with a header into the `category` table:

```
COPY category FROM 'categories.csv' (HEADER);
```

Copy the contents of `lineitem.tbl` into the `lineitem` table, where the contents are delimited by a pipe character (`|`):

```
COPY lineitem FROM 'lineitem.tbl' (DELIMITER '|');
```

Copy the contents of `lineitem.tbl` into the `lineitem` table, where the delimiter, quote character, and presence of a header are automatically detected:

```
COPY lineitem FROM 'lineitem.tbl' (AUTO_DETECT true);
```

Read the contents of a comma-separated file `names.csv` into the `name` column of the `category` table. Any other columns of this table are filled with their default value:

```
COPY category(name) FROM 'names.csv';
```

Read the contents of a Parquet file `lineitem.parquet` into the `lineitem` table:

```
COPY lineitem FROM 'lineitem.parquet' (FORMAT parquet);
```

Read the contents of a newline-delimited JSON file `lineitem.ndjson` into the `lineitem` table:

```
COPY lineitem FROM 'lineitem.ndjson' (FORMAT json);
```

Read the contents of a JSON file `lineitem.json` into the `lineitem` table:

```
COPY lineitem FROM 'lineitem.json' (FORMAT json, ARRAY true);
```

An expression may be used as the source of a COPY ... FROM command if it is placed within parentheses.

Read the contents of a file whose path is stored in a variable into the lineitem table:

```
SET VARIABLE source_file = 'lineitem.json';
COPY lineitem FROM (getvariable('source_file'));
```

Read the contents of a file provided as parameter of a prepared statement into the lineitem table:

```
PREPARE v1 AS COPY lineitem FROM ($1);
EXECUTE v1('lineitem.json');
```

Syntax

> To ensure compatibility with PostgreSQL, DuckDB accepts COPY ... FROM statements that do not fully comply with the railroad diagram shown here. For example, the following is a valid statement:
>
> ```
> COPY tbl FROM 'tbl.csv' WITH DELIMITER '|' CSV HEADER;
> ```

COPY ... TO

COPY ... TO exports data from DuckDB to an external CSV, Parquet, JSON or BLOB file. It has mostly the same set of options as COPY ... FROM, however, in the case of COPY ... TO the options specify how the file should be written to disk. Any file created by COPY ... TO can be copied back into the database by using COPY ... FROM with a similar set of options.

The COPY ... TO function can be called specifying either a table name, or a query. When a table name is specified, the contents of the entire table will be written into the resulting file. When a query is specified, the query is executed and the result of the query is written to the resulting file.

Copy the contents of the lineitem table to a CSV file with a header:

```
COPY lineitem TO 'lineitem.csv';
```

Copy the contents of the lineitem table to the file lineitem.tbl, where the columns are delimited by a pipe character (|), including a header line:

```
COPY lineitem TO 'lineitem.tbl' (DELIMITER '|');
```

Use tab separators to create a TSV file without a header:

```
COPY lineitem TO 'lineitem.tsv' (DELIMITER '\t', HEADER false);
```

Copy the l_orderkey column of the lineitem table to the file orderkey.tbl:

```
COPY lineitem(l_orderkey) TO 'orderkey.tbl' (DELIMITER '|');
```

Copy the result of a query to the file query.csv, including a header with column names:

```
COPY (SELECT 42 AS a, 'hello' AS b) TO 'query.csv' (DELIMITER ',');
```

Copy the result of a query to the Parquet file query.parquet:

```
COPY (SELECT 42 AS a, 'hello' AS b) TO 'query.parquet' (FORMAT parquet);
```

Copy the result of a query to the newline-delimited JSON file query.ndjson:

```
COPY (SELECT 42 AS a, 'hello' AS b) TO 'query.ndjson' (FORMAT json);
```

Copy the result of a query to the JSON file query.json:

```
COPY (SELECT 42 AS a, 'hello' AS b) TO 'query.json' (FORMAT json, ARRAY true);
```

Return the files and their column statistics that were written as part of the COPY statement:

```
COPY (SELECT l_orderkey, l_comment FROM lineitem) TO 'lineitem_part.parquet' (RETURN_STATS);
```

filename	count	file_size_bytes	footer_size_bytes	column_statistics	partition_keys
lineitem_part.parquet	600572	8579141	1445	{'"l_comment"'={column_size_bytes=7642227, max=zzle. slyly, min=' Tiresias above the blit', null_count=0}, '"l_orderkey"'={column_size_bytes=935457, max=600000, min=1, null_count=0}}	NULL

Note: for nested columns (e.g., structs) the column statistics are defined for each part. For example, if we have a column `name STRUCT(field1 INTEGER, field2 INTEGER)` the column statistics will have stats for `name.field1` and `name.field2`.

An expression may be used as the target of a `COPY ... TO` command if it is placed within parentheses.

Copy the result of a query to a file whose path is stored in a variable:

```
SET VARIABLE target_file = 'target_file.parquet';
COPY (SELECT 'hello world') TO (getvariable('target_file'));
```

Copy to a file provided as parameter of a prepared statement:

```
PREPARE v1 AS COPY (SELECT 42 AS i) to $1;
EXECUTE v1('file.csv');
```

Expressions may be used for options as well. Copy to a file using a format stored in a variable:

```
SET VARIABLE my_format = 'parquet';
COPY (SELECT 42 AS i) TO 'file' (FORMAT getvariable('my_format'));
```

`COPY ... TO` Options

Zero or more copy options may be provided as a part of the copy operation. The `WITH` specifier is optional, but if any options are specified, the parentheses are required. Parameter values can be passed in with or without wrapping in single quotes. Arbitrary expressions may be used for parameter values.

Any option that is a Boolean can be enabled or disabled in multiple ways. You can write `true`, `ON`, or `1` to enable the option, and `false`, `OFF`, or `0` to disable it. The `BOOLEAN` value can also be omitted, e.g., by only passing `(HEADER)`, in which case `true` is assumed.

With few exceptions, the below options are applicable to all formats written with `COPY`.

Name	Description	Type	Default
`FORMAT`	Specifies the copy function to use. The default is selected from the file extension (e.g., `.parquet` results in a Parquet file being written/read). If the file extension is unknown `CSV` is selected. Vanilla DuckDB provides `CSV`, `PARQUET` and `JSON` but additional copy functions can be added by `extensions`.	`VARCHAR`	`auto`
`USE_TMP_FILE`	Whether or not to write to a temporary file first if the original file exists (`target.csv.tmp`). This prevents overwriting an existing file with a broken file in case the writing is cancelled.	`BOOL`	`auto`
`OVERWRITE_OR_IGNORE`	Whether or not to allow overwriting files if they already exist. Only has an effect when used with `PARTITION_BY`.	`BOOL`	`false`

Name	Description	Type	Default
`OVERWRITE`	When `true`, all existing files inside targeted directories will be removed (not supported on remote filesystems). Only has an effect when used with `PARTITION_BY`.	`BOOL`	`false`
`APPEND`	When `true`, in the event a filename pattern is generated that already exists, the path will be regenerated to ensure no existing files are overwritten. Only has an effect when used with `PARTITION_BY`.	`BOOL`	`false`
`FILENAME_PATTERN`	Set a pattern to use for the filename, can optionally contain `{uuid}` / `{uuidv4}` or `{uuidv7}` to be filled in with a generated UUID (v4 or v7, respectively), and `{i}`, which is replaced by an incrementing index. Only has an effect when used with `PARTITION_BY`.	`VARCHAR`	`auto`
`FILE_EXTENSION`	Set the file extension that should be assigned to the generated file(s).	`VARCHAR`	`auto`
`PER_THREAD_OUTPUT`	When `true`, the COPY command generates one file per thread, rather than one file in total. This allows for faster parallel writing.	`BOOL`	`false`
`FILE_SIZE_BYTES`	If this parameter is set, the COPY process creates a directory which will contain the exported files. If a file exceeds the set limit (specified as bytes such as `1000` or in human-readable format such as `1k`), the process creates a new file in the directory. This parameter works in combination with `PER_THREAD_OUTPUT`. Note that the size is used as an approximation, and files can be occasionally slightly over the limit.	`VARCHAR` or `BIGINT`	(empty)
`PARTITION_BY`	The columns to partition by using a Hive partitioning scheme, see the partitioned writes section.	`VARCHAR[]`	(empty)
`PRESERVE_ORDER`	Whether or not to preserve order during the copy operation. Defaults to the value of the `preserve_insertion_order` configuration option.	`BOOL`	(*)
`RETURN_FILES`	Whether or not to include the created filepath(s) (as a `files VARCHAR[]` column) in the query result.	`BOOL`	`false`
`RETURN_STATS`	Whether or not to return the files and their column statistics that were written as part of the COPY statement.	`BOOL`	`false`
`WRITE_PARTITION_COLUMNS`	Whether or not to write partition columns into files. Only has an effect when used with `PARTITION_BY`.	`BOOL`	`false`

Syntax

> To ensure compatibility with PostgreSQL, DuckDB accepts `COPY ... TO` statements that do not fully comply with the railroad diagram shown here. For example, the following is a valid statement:

```
COPY (SELECT 42 AS x, 84 AS y) TO 'out.csv' WITH DELIMITER '|' CSV HEADER;
```

COPY FROM DATABASE ... TO

The COPY FROM DATABASE ... TO statement copies the entire content from one attached database to another attached database. This includes the schema, including constraints, indexes, sequences, macros and the data itself.

```
ATTACH 'db1.db' AS db1;
CREATE TABLE db1.tbl AS SELECT 42 AS x, 3 AS y;
CREATE MACRO db1.two_x_plus_y(x, y) AS 2 * x + y;

ATTACH 'db2.db' AS db2;
COPY FROM DATABASE db1 TO db2;
SELECT db2.two_x_plus_y(x, y) AS z FROM db2.tbl;
```

z
87

To only copy the **schema** of db1 to db2 but omit copying the data, add SCHEMA to the statement:

```
COPY FROM DATABASE db1 TO db2 (SCHEMA);
```

Syntax

Format-Specific Options

CSV Options

The below options are applicable when writing CSV files.

Name	Description	Type	Default
COMPRESSION	The compression type for the file. By default this will be detected automatically from the file extension (e.g., `file.csv.gz` will use `gzip`, `file.csv.zst` will use `zstd`, and `file.csv` will use none). Options are none, `gzip`, `zstd`.	VARCHAR	`auto`
DATEFORMAT	Specifies the date format to use when writing dates. See Date Format.	VARCHAR	(empty)
DELIM or SEP	The character that is written to separate columns within each row.	VARCHAR	,
NEW_LINE	The character that is written to separate each row. Use escaped strings, e.g. `E'\x1e'`	VARCHAR	\n
ESCAPE	The character that should appear before a character that matches the `quote` value.	VARCHAR	"
FORCE_QUOTE	The list of columns to always add quotes to, even if not required.	VARCHAR[]	[]
HEADER	Whether or not to write a header for the CSV file.	BOOL	`true`
NULLSTR	The string that is written to represent a NULL value.	VARCHAR	(empty)
PREFIX	Prefixes the CSV file with a specified string. This option must be used in conjunction with SUFFIX and requires HEADER to be set to `false`.	VARCHAR	(empty)

Name	Description	Type	Default
SUFFIX	Appends a specified string as a suffix to the CSV file. This option must be used in conjunction with PREFIX and requires HEADER to be set to false.	VARCHAR	(empty)
QUOTE	The quoting character to be used when a data value is quoted.	VARCHAR	"
TIMESTAMPFORMAT	Specifies the date format to use when writing timestamps. See Date Format.	VARCHAR	(empty)

Parquet Options

The below options are applicable when writing Parquet files.

Name	Description	Type	Default
COMPRESSION	The compression format to use (uncompressed, snappy, gzip, zstd, brotli, lz4, lz4_raw).	VARCHAR	snappy
COMPRESSION_LEVEL	Compression level, set between 1 (lowest compression, fastest) and 22 (highest compression, slowest). Only supported for zstd compression.	BIGINT	3
FIELD_IDS	The field_id for each column. Pass auto to attempt to infer automatically.	STRUCT	(empty)
ROW_GROUP_SIZE_BYTES	The target size of each row group. You can pass either a human-readable string, e.g., 2MB, or an integer, i.e., the number of bytes. This option is only used when you have issued SET preserve_insertion_order = false;, otherwise, it is ignored.	BIGINT	row_group_size * 1024
ROW_GROUP_SIZE	The target size, i.e., number of rows, of each row group.	BIGINT	122880
ROW_GROUPS_PER_FILE	Create a new Parquet file if the current one has a specified number of row groups. If multiple threads are active, the number of row groups in a file may slightly exceed the specified number of row groups to limit the amount of locking – similarly to the behavior of FILE_SIZE_BYTES. However, if per_thread_output is set, only one thread writes to each file, and it becomes accurate again.	BIGINT	(empty)
PARQUET_VERSION	The Parquet version to use (V1, V2).	VARCHAR	V1
CHUNK_SIZE	Alias for ROW_GROUP_SIZE.	BIGINT	122880
KV_METADATA	Custom key-value metadata to embed in the file footer, supplied as a STRUCT of keys to values. BLOB values are written as raw bytes; other values are cast to string.	STRUCT	(empty)
SHREDDING	A STRUCT mapping VARIANT column names to the type they should be shredded into, e.g., {variant_col: 'STRUCT(name VARCHAR, age INTEGER)'}. Enables typed (shredded) storage of VARIANT columns.	STRUCT	(empty)
DICTIONARY_SIZE_LIMIT	The maximum size of the dictionary used for dictionary encoding, in number of distinct values. Set to 0 to disable dictionary encoding.	BIGINT	ROW_GROUP_SIZE / 5

Name	Description	Type	Default
WRITE_BLOOM_FILTER	Whether to write Bloom filters that allow readers to skip row groups.	BOOLEAN	true
BLOOM_FILTER_FALSE_POSITIVE_RATIO	The target false positive ratio of the written Bloom filters.	DOUBLE	0.01
GEOPARQUET_VERSION	Which GeoParquet metadata version to write for geometry columns (NONE, V1, V2, BOTH). NONE disables GeoParquet metadata.	VARCHAR	V1

Some examples of FIELD_IDS are as follows.

Assign field_ids automatically:

```
COPY
    (SELECT 128 AS i)
    TO 'my.parquet'
    (FIELD_IDS 'auto');
```

Sets the field_id of column i to 42:

```
COPY
    (SELECT 128 AS i)
    TO 'my.parquet'
    (FIELD_IDS {i: 42});
```

Sets the field_id of column i to 42, and column j to 43:

```
COPY
    (SELECT 128 AS i, 256 AS j)
    TO 'my.parquet'
    (FIELD_IDS {i: 42, j: 43});
```

Sets the field_id of column my_struct to 42, and column i (nested inside my_struct) to 43:

```
COPY
    (SELECT {i: 128} AS my_struct)
    TO 'my.parquet'
    (FIELD_IDS {my_struct: {__duckdb_field_id: 42, i: 43}});
```

Sets the field_id of column my_list to 42, and column element (default name of list child) to 43:

```
COPY
    (SELECT [128, 256] AS my_list)
    TO 'my.parquet'
    (FIELD_IDS {my_list: {__duckdb_field_id: 42, element: 43}});
```

Sets the field_id of column my_map to 42, and columns key and value (default names of map children) to 43 and 44:

```
COPY
    (SELECT MAP {'key1' : 128, 'key2': 256} my_map)
    TO 'my.parquet'
    (FIELD_IDS {my_map: {__duckdb_field_id: 42, key: 43, value: 44}});
```

JSON Options

The below options are applicable when writing JSON files.

Name	Description	Type	Default
ARRAY	Whether to write a JSON array. If `true`, a JSON array of records is written, if `false`, newline-delimited JSON is written	BOOL	`false`
COMPRESSION	The compression type for the file. By default this will be detected automatically from the file extension (e.g., `file.json.gz` will use `gzip`, `file.json.zst` will use `zstd`, and `file.json` will use none). Options are none, `gzip`, `zstd`.	VARCHAR	`auto`
DATEFORMAT	Specifies the date format to use when writing dates. See Date Format.	VARCHAR	(empty)
TIMESTAMPFORMAT	Specifies the date format to use when writing timestamps. See Date Format.	VARCHAR	(empty)

Sets the value of column `hello` to `QUACK!` and outputs the results to `quack.json`:

```
COPY (SELECT 'QUACK!' AS hello) TO 'quack.json';
--RETURNS: {"hello":"QUACK!"}
```

Sets the value of column `num_list` to `[1,2,3]` and outputs the results to `numbers.json`:

```
COPY (SELECT [1, 2, 3] AS num_list) TO 'numbers.json';
--RETURNS: {"num_list":[1,2,3]}
```

Sets the value of column `compression_type` to `gzip_explicit` and outputs the results to `compression.json.gz` with explicit compression:

```
COPY (SELECT 'gzip_explicit' AS compression_type) TO 'explicit_compression.json' (FORMAT json,
COMPRESSION 'GZIP');
-- RETURNS: {"compression_type":"gzip_explicit"}
```

Sets all values of single rows to be returned as nested arrays to `array_true.json`:

```
COPY (SELECT 1 AS id, 'Alice' AS name, [1, 2, 3] AS numbers
      UNION ALL
      SELECT 2, 'Bob', [4, 5, 6] AS numbers)
TO 'array_true.json' (FORMAT json, ARRAY true);

-- RETURNS:
/*
[
    {"id":1,"name":"Alice","numbers":[1,2,3]},
    {"id":2,"name":"Bob","numbers":[1,2,3]}
]
*/
```

Sets all values of single rows to be returned as non-nested arrays to `array_false.json`:

```
COPY (SELECT 1 AS id, 'Alice' AS name, [1, 2, 3] AS numbers
      UNION ALL
      SELECT 2, 'Bob', [4, 5, 6] AS numbers)
TO 'array_false.json' (FORMAT json, ARRAY false);

-- RETURNS:
/*
{"id":1,"name":"Alice","numbers":[1,2,3]}
{"id":2,"name":"Bob","numbers":[4,5,6]}
*/
```

BLOB Options

The BLOB format option allows you to select a single column of a DuckDB table into a `.blob` file. The column must be cast to the BLOB data type. For details on typecasting, see the Casting Operations Matrix.

The below options are applicable when writing BLOB files.

Name	Description	Type	Default
COMPRESSION	The compression type for the file. By default this will be detected automatically from the file extension (e.g., `file.blob.gz` will use `gzip`, `file.blob.zst` will use `zstd`, and `file.blob` will use none). Options are none, `gzip`, `zstd`.	VARCHAR	`auto`

Type casts the string value `foo` to the BLOB data type and outputs the results to `blob_output.blob`:

```
COPY (select 'foo'::BLOB) TO 'blob_output.blob' (FORMAT BLOB);
```

Type casts the string value `foo` to the BLOB data type and outputs the results to `blob_output_gzip.blob.gz` with `gzip` compression:

```
COPY (select 'foo'::BLOB) TO 'blob_output_gzip.blob' (FORMAT BLOB, COMPRESSION 'GZIP');
```

Limitations

COPY does not support copying between tables. To copy between tables, use an `INSERT statement`:

```
INSERT INTO tbl2
    FROM tbl1;
```

CREATE MACRO Statement

The `CREATE MACRO` statement can create a scalar or table macro (function) in the catalog.

For a scalar macro, `CREATE MACRO` is followed by the name of the macro, and optionally parameters within a set of parentheses. The keyword `AS` is next, followed by the text of the macro. By design, a scalar macro may only return a single value. For a table macro, the syntax is similar to a scalar macro except `AS` is replaced with `AS TABLE`. A table macro may return a table of arbitrary size and shape.

> If a MACRO is temporary, it is only usable within the same database connection and is deleted when the connection is closed.

Examples

Scalar Macros

Create a macro that adds two expressions (a and b):

```
CREATE MACRO add(a, b) AS a + b;
```

Create a macro, replacing possible existing definitions:

```
CREATE OR REPLACE MACRO add(a, b) AS a + b;
```

Create a macro if it does not already exist, else do nothing:

```
CREATE MACRO IF NOT EXISTS add(a, b) AS a + b;
```

Create a macro for a CASE expression:

```
CREATE MACRO ifelse(a, b, c) AS CASE WHEN a THEN b ELSE c END;
```

Create a macro that does a subquery:

```
CREATE MACRO one() AS (SELECT 1);
```

Macros are schema-dependent, and have an alias, FUNCTION:

```
CREATE FUNCTION main.my_avg(x) AS sum(x) / count(x);
```

Create a macro with a default parameter:

```
CREATE MACRO add_default(a, b := 5) AS a + b;
```

Create a macro `arr_append` (with a functionality equivalent to `array_append`):

```
CREATE MACRO arr_append(l, e) AS list_concat(l, list_value(e));
```

Create a macro with a typed parameter:

```
CREATE MACRO is_maximal(a INTEGER) AS a = 2^31 - 1;
```

Table Macros

Create a table macro without parameters:

```
CREATE MACRO static_table() AS TABLE
    SELECT 'Hello' AS column1, 'World' AS column2;
```

Create a table macro with parameters (that can be of any type):

```
CREATE MACRO dynamic_table(col1_value, col2_value) AS TABLE
    SELECT col1_value AS column1, col2_value AS column2;
```

Create a table macro that returns multiple rows. It will be replaced if it already exists, and it is temporary (will be automatically deleted when the connection ends):

```
CREATE OR REPLACE TEMP MACRO dynamic_table(col1_value, col2_value) AS TABLE
    SELECT col1_value AS column1, col2_value AS column2
    UNION ALL
    SELECT 'Hello' AS col1_value, 456 AS col2_value;
```

Pass an argument as a list:

```
CREATE MACRO get_users(i) AS TABLE
    SELECT * FROM users WHERE uid IN (SELECT unnest(i));
```

An example for how to use the `get_users` table macro is the following:

```
CREATE TABLE users AS
    SELECT *
    FROM (VALUES (1, 'Ada'), (2, 'Bob'), (3, 'Carl'), (4, 'Dan'), (5, 'Eve')) t(uid, name);
SELECT * FROM get_users([1, 5]);
```

To define macros on arbitrary tables, use the `query_table` function. For example, the following macro computes a column-wise checksum on a table:

```
CREATE MACRO checksum(tbl) AS TABLE
    SELECT bit_xor(md5_number(COLUMNS(*)::VARCHAR))
    FROM query_table(tbl);

CREATE TABLE tbl AS SELECT unnest([42, 43]) AS x, 100 AS y;
SELECT * FROM checksum('tbl');
```

Overloading

It is possible to overload a macro based on the types or the number of its parameters; this works for both scalar and table macros.

By providing overloads we can have both `add_x(a, b)` and `add_x(a, b, c)` with different function bodies.

```
CREATE MACRO add_x
    (a, b) AS a + b,
    (a, b, c) AS a + b + c;

SELECT
    add_x(21, 42) AS two_args,
    add_x(21, 42, 21) AS three_args;
```

two_args	three_args
63	84

```
CREATE OR REPLACE MACRO is_maximal
    (a TINYINT) AS a = 2^7 - 1,
    (a INT) AS a = 2^31 - 1;

SELECT
    is_maximal(127::TINYINT) AS tiny,
    is_maximal(127) AS regular;
```

tiny	regular
true	false

Syntax

Macros allow you to create shortcuts for combinations of expressions.

```
CREATE MACRO add(a) AS a + b;
```

```
Binder Error:
Referenced column "b" not found in FROM clause!
```

This works:

```
CREATE MACRO add(a, b) AS a + b;
```

Usage example:

```
SELECT add(1, 2) AS x;
```

x
3

However, this fails:

```
SELECT add('hello', 3);
```

```
Binder Error:
Could not choose a best candidate function for the function call "add(STRING_LITERAL, INTEGER_LITERAL)".
In order to select one, please add explicit type casts.
    Candidate functions:
    add(DATE, INTEGER) -> DATE
    add(INTEGER, INTEGER) -> INTEGER
```

Macros can have default parameters.

b is a default parameter:

```
CREATE MACRO add_default(a, b := 5) AS a + b;
```

The following will result in 42:

```
SELECT add_default(37);
```

The order of named parameters does not matter:

```
CREATE MACRO triple_add(a, b := 5, c := 10) AS a + b + c;
```

```
SELECT triple_add(40, c := 1, b := 1) AS x;
```

x
42

When macros are used, they are expanded (i.e., replaced with the original expression), and the parameters within the expanded expression are replaced with the supplied arguments. Step by step:

The add macro we defined above is used in a query:

```
SELECT add(40, 2) AS x;
```

Internally, add is replaced with its definition of a + b:

```
SELECT a + b AS x;
```

Then, the parameters are replaced by the supplied arguments:

```
SELECT 40 + 2 AS x;
```

Limitations

Using Subquery Macros

Table macros as well as scalar macros defined using scalar subqueries cannot be used in the arguments of table functions. DuckDB will return the following error:

```
Binder Error:
Table function cannot contain subqueries
```

Overloads

Overloads for macro functions have to be set at creation, it is not possible to define a macro by the same name twice without first removing the first definition.

Recursive Functions

Defining recursive functions is not supported. For example, the following macro – supposed to compute the *n*th number of the Fibonacci sequence – fails:

```
CREATE OR REPLACE FUNCTION fibo(n) AS (SELECT 1);
CREATE OR REPLACE FUNCTION fibo(n) AS (
    CASE
        WHEN n <= 1 THEN 1
        ELSE fibo(n - 1)
    END
);
SELECT fibo(3);
```

```
Binder Error:
Max expression depth limit of 1000 exceeded. Use "SET max_expression_depth TO x" to increase the maximum
expression depth.
```

Function Chaining on the First Function Does Not Work

Macros do not support the dot operator for function chaining on the first function. To illustrate this, see an example with the `lower` function, which works:

```
CREATE OR REPLACE MACRO low(s) AS lower(s);
SELECT low('AA');
```

However, rewriting `lower(s)` to use function chaining does not work:

```
CREATE OR REPLACE MACRO low(s) AS s.lower();
SELECT low('AA');
```

```
Binder Error:
Referenced column "s" not found in FROM clause!
```

Viewing the List of Macros and Table Macros

You can use the following query to display the list of macros and table macros:

```
SELECT schema_name, function_name, function_type, parameters
FROM duckdb_functions();
```

CREATE SCHEMA Statement

The `CREATE SCHEMA` statement creates a schema in the catalog. The default schema is `main`.

Examples

Create a schema:

```
CREATE SCHEMA s1;
```

Create a schema if it does not exist yet:

```
CREATE SCHEMA IF NOT EXISTS s2;
```

Create a schema or replace a schema if it exists:

```
CREATE OR REPLACE SCHEMA s2;
```

Create table in the schemas:

```
CREATE TABLE s1.t (id INTEGER PRIMARY KEY, other_id INTEGER);
CREATE TABLE s2.t (id INTEGER PRIMARY KEY, j VARCHAR);
```

Compute a join between tables from two schemas:

```
SELECT *
FROM s1.t s1t, s2.t s2t
WHERE s1t.other_id = s2t.id;
```

Syntax

CREATE SECRET Statement

The `CREATE SECRET` statement creates a new secret in the Secrets Manager.

Syntax for CREATE SECRET

> **Warning.** When using the command line client, the `CREATE SECRET` statements are stored in your DuckDB history as plain text.

Syntax for DROP SECRET

CREATE SEQUENCE Statement

The `CREATE SEQUENCE` statement creates a new sequence number generator.

Examples

Generate an ascending sequence starting from 1:

```
CREATE SEQUENCE serial;
```

Generate sequence from a given start number:

```
CREATE SEQUENCE serial START 101;
```

Generate odd numbers using `INCREMENT BY`:

```
CREATE SEQUENCE serial START WITH 1 INCREMENT BY 2;
```

Generate a descending sequence starting from 99:

```
CREATE SEQUENCE serial START WITH 99 INCREMENT BY -1 MAXVALUE 99;
```

By default, cycles are not allowed and will result in error, e.g.:

```
Sequence Error:
nextval: reached maximum value of sequence "serial" (10)
```

```
CREATE SEQUENCE serial START WITH 1 MAXVALUE 10;
```

`CYCLE` allows cycling through the same sequence repeatedly:

```
CREATE SEQUENCE serial START WITH 1 MAXVALUE 10 CYCLE;
```

Creating and Dropping Sequences

Sequences can be created and dropped similarly to other catalog items.

Overwrite an existing sequence:

```
CREATE OR REPLACE SEQUENCE serial;
```

Only create sequence if no such sequence exists yet:

```
CREATE SEQUENCE IF NOT EXISTS serial;
```

Remove sequence:

```
DROP SEQUENCE serial;
```

Remove sequence if exists:

```
DROP SEQUENCE IF EXISTS serial;
```

Using Sequences for Primary Keys

Sequences can be used as `DEFAULT` values in `CREATE TABLE` statements.

The example below uses a sequence to create an integer primary key:

```
CREATE SEQUENCE id_sequence START 1;
CREATE TABLE tbl (id INTEGER PRIMARY KEY DEFAULT nextval('id_sequence'), s VARCHAR);
INSERT INTO tbl (s) VALUES ('hello'), ('world');
SELECT * FROM tbl;
```

The script results in the following table:

id	s
1	hello
2	world

Sequences can also be added using the `ALTER TABLE` statement. The following example adds an `id` column and fills it with values generated by the sequence:

```
CREATE TABLE tbl (s VARCHAR);
INSERT INTO tbl VALUES ('hello'), ('world');
CREATE SEQUENCE id_sequence START 1;
ALTER TABLE tbl ADD COLUMN id INTEGER DEFAULT nextval('id_sequence');
SELECT * FROM tbl;
```

This script results in the same table as the previous example.

Selecting the Next Value

To select the next number from a sequence, use `nextval`:

```
CREATE SEQUENCE serial START 1;
SELECT nextval('serial') AS nextval;
```

nextval
1

Using this sequence in an `INSERT` command:

```
INSERT INTO distributors VALUES (nextval('serial'), 'nothing');
```

Selecting the Current Value

You may also view the current number from the sequence. Note that the `nextval` function must have already been called before calling `currval`, otherwise a Serialization Error (`sequence is not yet defined in this session`) will be thrown.

```
CREATE SEQUENCE serial START 1;
SELECT nextval('serial') AS nextval;
SELECT currval('serial') AS currval;
```

currval
1

Syntax

`CREATE SEQUENCE` creates a new sequence number generator.

If a schema name is given then the sequence is created in the specified schema. Otherwise it is created in the current schema. Temporary sequences exist in a special schema, so a schema name may not be given when creating a temporary sequence. The sequence name must be distinct from the name of any other sequence in the same schema.

After a sequence is created, you use the function `nextval` to operate on the sequence.

Parameters

Name	Description
`CYCLE` or `NO CYCLE`	The `CYCLE` option allows the sequence to wrap around when the `maxvalue` or `minvalue` has been reached by an ascending or descending sequence respectively. If the limit is reached, the next number generated will be the `minvalue` or `maxvalue`, respectively. If `NO CYCLE` is specified, any calls to `nextval` after the sequence has reached its maximum value will return an error. If neither `CYCLE` nor `NO CYCLE` are specified, `NO CYCLE` is the default.
`increment`	The optional clause `INCREMENT BY increment` specifies which value is added to the current sequence value to create a new value. A positive value will make an ascending sequence, a negative one a descending sequence. The default value is 1.
`maxvalue`	The optional clause `MAXVALUE maxvalue` determines the maximum value for the sequence. If this clause is not supplied or `NO MAXVALUE` is specified, then default values will be used. The defaults are 2^63 - 1 and -1 for ascending and descending sequences, respectively.

Name	Description
`minvalue`	The optional clause `MINVALUE minvalue` determines the minimum value a sequence can generate. If this clause is not supplied or `NO MINVALUE` is specified, then defaults will be used. The defaults are 1 and -(2^63 - 1) for ascending and descending sequences, respectively.
`name`	The name (optionally schema-qualified) of the sequence to be created.
`start`	The optional clause `START WITH start` allows the sequence to begin anywhere. The default starting value is `minvalue` for ascending sequences and `maxvalue` for descending ones.
TEMPORARY or TEMP	If specified, the sequence object is created only for this session, and is automatically dropped on session exit. Existing permanent sequences with the same name are not visible (in this session) while the temporary sequence exists, unless they are referenced with schema-qualified names.

> Sequences are based on `BIGINT` arithmetic, so the range cannot exceed the range of an eight-byte integer (-9223372036854775808 to 9223372036854775807).

Limitations

Due to limitations in DuckDB's dependency manager, `DROP SEQUENCE` will fail in some corner cases.

```
CREATE SEQUENCE id_sequence START 1;

CREATE TABLE tbl (
    id INTEGER DEFAULT nextval('id_sequence'),
    s VARCHAR
);
INSERT INTO tbl(s) VALUES ('default is the next value from id_sequence');

ALTER TABLE tbl ALTER COLUMN id SET DEFAULT NULL;
INSERT INTO tbl(s) VALUES ('default is NULL');

SELECT * FROM tbl;
```

id	s
int32	varchar
1	default is the next value from id_sequence
NULL	default is NULL

Even though the sequence is no longer used, attempting to drop it results in an error:

```
DROP SEQUENCE id_sequence;
```

```
Dependency Error:
Cannot drop entry "id_sequence" because there are entries that depend on it.
table "tbl" depends on index "id_sequence".
Use DROP...CASCADE to drop all dependents.
```

As the error message suggests, you can force dropping by adding CASCADE. However, DuckDB currently tracks dependencies at the table level, so attempting to drop with CASCADE drops the entire table:

```
DROP SEQUENCE id_sequence CASCADE;
SELECT * FROM tbl;
```

```
Catalog Error:
Table with name tbl does not exist!
```

CREATE TABLE Statement

The `CREATE TABLE` statement creates a table in the catalog.

Examples

Create a table with two integer columns (`i` and `j`):

```
CREATE TABLE t1 (i INTEGER, j INTEGER);
```

Create a table with a primary key:

```
CREATE TABLE t1 (id INTEGER PRIMARY KEY, j VARCHAR);
```

Create a table with a composite primary key:

```
CREATE TABLE t1 (id INTEGER, j VARCHAR, PRIMARY KEY (id, j));
```

Create a table with various different types, constraints and default values:

```
CREATE TABLE t1 (
    i INTEGER NOT NULL DEFAULT 0,
    decimalnr DOUBLE CHECK (decimalnr < 10),
    date DATE UNIQUE,
    time TIMESTAMP
);
```

Create table with `CREATE TABLE ... AS SELECT` (CTAS):

```
CREATE TABLE t1 AS
    SELECT 42 AS i, 84 AS j;
```

Create a table from a CSV file (automatically detecting column names and types):

```
CREATE TABLE t1 AS
    SELECT *
    FROM read_csv('path/file.csv');
```

We can use the FROM-first syntax to omit `SELECT *`:

```
CREATE TABLE t1 AS
    FROM read_csv('path/file.csv');
```

Copy the schema of `t2` to `t1`:

```
CREATE TABLE t1 AS
    FROM t2
    LIMIT 0;
```

Note that only the column names and types are copied to `t1`, other pieces of information (indexes, constraints, default values, etc.) are not copied.

Temporary Tables

Temporary tables are session scoped, meaning that only the specific connection that created them can access them and once the connection to DuckDB is closed they will be automatically dropped (similar to PostgreSQL, for example).

They can be created using the `CREATE TEMP TABLE` or the `CREATE TEMPORARY TABLE` statement (see diagram below) and are part of the `temp.main` schema. While discouraged, their names can overlap with the names of the regular database tables. In these cases, temporary tables take priority in name resolution and full qualification is required to refer to a regular table e.g., `memory.main.t1`.

Temporary tables reside in memory rather than on disk even when connecting to a persistent DuckDB, but if the `temp_directory` configuration is set, data will be spilled to disk if memory becomes constrained.

Create a temporary table from a CSV file (automatically detecting column names and types):

```
CREATE TEMP TABLE t1 AS
    SELECT *
    FROM read_csv('path/file.csv');
```

Allow temporary tables to off-load excess memory to disk:

```
SET temp_directory = '/path/to/directory/';
```

CREATE OR REPLACE

The `CREATE OR REPLACE` syntax allows a new table to be created or for an existing table to be overwritten by the new table. This is shorthand for dropping the existing table and then creating the new one.

Create a table with two integer columns (i and j) even if t1 already exists:

```
CREATE OR REPLACE TABLE t1 (i INTEGER, j INTEGER);
```

IF NOT EXISTS

The `IF NOT EXISTS` syntax will only proceed with the creation of the table if it does not already exist. If the table already exists, no action will be taken and the existing table will remain in the database.

Create a table with two integer columns (`i` and `j`) only if `t1` does not exist yet:

```
CREATE TABLE IF NOT EXISTS t1 (i INTEGER, j INTEGER);
```

CREATE TABLE ... AS SELECT (CTAS)

DuckDB supports the `CREATE TABLE ... AS SELECT` syntax, also known as "CTAS":

```
CREATE TABLE nums AS
    SELECT i
    FROM range(0, 3) t(i);
```

This syntax can be used in combination with the CSV reader, the shorthand to read directly from CSV files without specifying a function, the FROM-first syntax, and the HTTP(S) support, yielding concise SQL commands such as the following:

```
CREATE TABLE flights AS
    FROM 'https://duckdb.org/data/flights.csv';
```

The CTAS construct also works with the `OR REPLACE` modifier, yielding `CREATE OR REPLACE TABLE ... AS` statements:

```
CREATE OR REPLACE TABLE flights AS
    FROM 'https://duckdb.org/data/flights.csv';
```

Copying the Schema

You can create a copy of the table's schema (column names and types only) as follows:

```
CREATE TABLE t1 AS
    FROM t2
    WITH NO DATA;
```

Or:

```
CREATE TABLE t1 AS
    FROM t2
    LIMIT 0;
```

It is not possible to create tables using CTAS statements with constraints (primary keys, check constraints, etc.).

Check Constraints

A CHECK constraint is an expression that must be satisfied by the values of every row in the table.

```
CREATE TABLE t1 (
    id INTEGER PRIMARY KEY,
    percentage INTEGER CHECK (0 <= percentage AND percentage <= 100)
);
INSERT INTO t1 VALUES (1, 5);
INSERT INTO t1 VALUES (2, -1);
```

```
Constraint Error:
CHECK constraint failed: t1
```

```
INSERT INTO t1 VALUES (3, 101);
```

```
Constraint Error:
CHECK constraint failed: t1
```

```
CREATE TABLE t2 (id INTEGER PRIMARY KEY, x INTEGER, y INTEGER CHECK (x < y));
INSERT INTO t2 VALUES (1, 5, 10);
INSERT INTO t2 VALUES (2, 5, 3);
```

```
Constraint Error:
CHECK constraint failed: t2
```

CHECK constraints can also be added as part of the `CONSTRAINTS` clause:

```
CREATE TABLE t3 (
    id INTEGER PRIMARY KEY,
    x INTEGER,
    y INTEGER,
    CONSTRAINT x_smaller_than_y CHECK (x < y)
);
INSERT INTO t3 VALUES (1, 5, 10);
INSERT INTO t3 VALUES (2, 5, 3);
```

```
Constraint Error:
CHECK constraint failed: t3
```

Foreign Key Constraints

A `FOREIGN KEY` is a column (or set of columns) that references another table's primary key. Foreign keys check referential integrity, i.e., the referred primary key must exist in the other table upon insertion.

```
CREATE TABLE t1 (id INTEGER PRIMARY KEY, j VARCHAR);
CREATE TABLE t2 (
    id INTEGER PRIMARY KEY,
    t1_id INTEGER,
    FOREIGN KEY (t1_id) REFERENCES t1 (id)
);
```

Example:

```
INSERT INTO t1 VALUES (1, 'a');
INSERT INTO t2 VALUES (1, 1);
INSERT INTO t2 VALUES (2, 2);
```

```
Constraint Error:
Violates foreign key constraint because key "id: 2" does not exist in the referenced table
```

Foreign keys can be defined on composite primary keys:

```
CREATE TABLE t3 (id INTEGER, j VARCHAR, PRIMARY KEY (id, j));
CREATE TABLE t4 (
    id INTEGER PRIMARY KEY, t3_id INTEGER, t3_j VARCHAR,
    FOREIGN KEY (t3_id, t3_j) REFERENCES t3(id, j)
);
```

Example:

```
INSERT INTO t3 VALUES (1, 'a');
INSERT INTO t4 VALUES (1, 1, 'a');
INSERT INTO t4 VALUES (2, 1, 'b');
```

```
Constraint Error:
Violates foreign key constraint because key "id: 1, j: b" does not exist in the referenced table
```

Foreign keys can also be defined on unique columns:

```
CREATE TABLE t5 (id INTEGER UNIQUE, j VARCHAR);
CREATE TABLE t6 (
    id INTEGER PRIMARY KEY,
    t5_id INTEGER,
    FOREIGN KEY (t5_id) REFERENCES t5(id)
);
```

Limitations

Foreign keys have the following limitations.

Foreign keys with cascading deletes (`FOREIGN KEY ... REFERENCES ... ON DELETE CASCADE`) are not supported.

Inserting into tables with self-referencing foreign keys is currently not supported and will result in the following error:

```
Constraint Error:
Violates foreign key constraint because key "..." does not exist in the referenced table.
```

Generated Columns

The `[type] [GENERATED ALWAYS] AS (expr) [VIRTUAL|STORED]` syntax will create a generated column. The data in this kind of column is generated from its expression, which can reference other (regular or generated) columns of the table. Since they are produced by calculations, these columns cannot be inserted into directly.

DuckDB can infer the type of the generated column based on the expression's return type. This allows you to leave out the type when declaring a generated column. It is possible to explicitly set a type, but insertions into the referenced columns might fail if the type cannot be cast to the type of the generated column.

Generated columns come in two varieties: `VIRTUAL` and `STORED`. The data of virtual generated columns is not stored on disk, instead it is computed from the expression every time the column is referenced (through a select statement).

The data of stored generated columns is stored on disk and is computed every time the data of their dependencies change (through an `INSERT` / `UPDATE` / `DROP` statement).

Currently, only the `VIRTUAL` kind is supported, and it is also the default option if the last field is left blank.

The simplest syntax for a generated column:

The type is derived from the expression, and the variant defaults to `VIRTUAL`:

```
CREATE TABLE t1 (x FLOAT, two_x AS (2 * x));
```

Fully specifying the same generated column for completeness:

```
CREATE TABLE t1 (x FLOAT, two_x FLOAT GENERATED ALWAYS AS (2 * x) VIRTUAL);
```

Syntax

CREATE VIEW Statement

The `CREATE VIEW` statement defines a new view in the catalog.

Examples

Create a simple view:

```
CREATE VIEW view1 AS SELECT * FROM tbl;
```

Create a view or replace it if a view with that name already exists:

```
CREATE OR REPLACE VIEW view1 AS SELECT 42;
```

Create a view and replace the column names:

```
CREATE VIEW view1(a) AS SELECT 42;
```

The SQL query behind an existing view can be read using the `duckdb_views()` function like this:

```
SELECT sql FROM duckdb_views() WHERE view_name = 'view1';
```

Syntax

`CREATE VIEW` defines a view of a query. The view is not physically materialized. Instead, the query is run every time the view is referenced in a query.

`CREATE OR REPLACE VIEW` is similar, but if a view of the same name already exists, it is replaced.

If a schema name is given then the view is created in the specified schema. Otherwise, it is created in the current schema. Temporary views exist in a special schema, so a schema name cannot be given when creating a temporary view. The name of the view must be distinct from the name of any other view or table in the same schema.

CREATE TYPE Statement

The `CREATE TYPE` statement defines a new type in the catalog.

Examples

Create a simple ENUM type:

```
CREATE TYPE mood AS ENUM ('happy', 'sad', 'curious');
```

Create a simple STRUCT type:

```
CREATE TYPE many_things AS STRUCT(k INTEGER, l VARCHAR);
```

Create a simple UNION type:

```
CREATE TYPE one_thing AS UNION(number INTEGER, string VARCHAR);
```

Create a type alias:

```
CREATE TYPE x_index AS INTEGER;
```

Syntax

The `CREATE TYPE` clause defines a new data type available to this DuckDB instance. These new types can then be inspected in the `duckdb_types` table.

Limitations

- Extending types to support custom operators (such as the PostgreSQL && operator) is not possible via plain SQL. Instead, it requires adding additional C++ code. To do this, create an extension.
- The `CREATE TYPE` clause does not support the `OR REPLACE` modifier.

DELETE Statement

The `DELETE` statement removes rows from the table identified by the table-name. If the `WHERE` clause is not present, all records in the table are deleted. If a `WHERE` clause is supplied, then only those rows for which the `WHERE` clause results in true are deleted. Rows for which the expression is false or `NULL` are retained.

Examples

Remove the rows matching the condition `i = 2` from the database:

```
DELETE FROM tbl WHERE i = 2;
```

Delete all rows in the table `tbl`:

```
DELETE FROM tbl;
```

`USING` Clause

The `USING` clause allows deleting based on the content of other tables or subqueries.

`RETURNING` Clause

The `RETURNING` clause allows returning the deleted values. It uses the same syntax as the `SELECT` clause except the `DISTINCT` modifier is not supported.

```
CREATE TABLE employees (name VARCHAR, age INTEGER);
INSERT INTO employees VALUES ('Kat', 32);
DELETE FROM employees RETURNING name, 2025 - age AS approx_birthyear;
```

name	approx_birthyear
Kat	1993

Syntax

The TRUNCATE Statement

The `TRUNCATE` statement removes all rows from a table, acting as an alias for `DELETE FROM` without a `WHERE` clause:

```
TRUNCATE tbl;
```

Limitations on Reclaiming Memory and Disk Space

Running `DELETE` does not mean space is reclaimed. In general, rows are only marked as deleted. DuckDB reclaims space upon performing a `CHECKPOINT`. `VACUUM` currently does not reclaim space.

DESCRIBE Statement

The `DESCRIBE` statement shows the schema of a table, view or query.

Usage

```
DESCRIBE tbl;
```

To describe a query, prepend `DESCRIBE` to a query.

```
DESCRIBE SELECT * FROM tbl;
```

Alias

The `SHOW` statement is an alias for `DESCRIBE`.

See Also

For more examples, see the guide on `DESCRIBE`.

DROP Statement

The `DROP` statement removes a catalog entry added previously with the `CREATE` command.

Examples

Delete the table with the name `tbl`:

```
DROP TABLE tbl;
```

Drop the view with the name `view1`; do not throw an error if the view does not exist:

```
DROP VIEW IF EXISTS view1;
```

Drop function `fn`:

```
DROP FUNCTION fn;
```

Drop index `idx`:

```
DROP INDEX idx;
```

Drop schema `sch`:

```
DROP SCHEMA sch;
```

Drop sequence `seq`:

```
DROP SEQUENCE seq;
```

Drop macro `mcr`:

```
DROP MACRO mcr;
```

Drop macro table `mt`:

```
DROP MACRO TABLE mt; -- the `TABLE` is optional since v1.4.0
```

Drop type `typ`:

```
DROP TYPE typ;
```

Syntax

Dependencies of Dropped Objects

DuckDB performs limited dependency tracking for some object types. By default or if the `RESTRICT` clause is provided, the entry will not be dropped if there are any other objects that depend on it. If the `CASCADE` clause is provided then all the objects that are dependent on the object will be dropped as well.

```
CREATE SCHEMA myschema;
CREATE TABLE myschema.t1 (i INTEGER);
DROP SCHEMA myschema;
```

```
Dependency Error:
Cannot drop entry "myschema" because there are entries that depend on it.
table "t1" depends on schema "myschema".
Use DROP...CASCADE to drop all dependents.
```

The CASCADE modifier drops both myschema and `myschema.t1`:

```
CREATE SCHEMA myschema;
CREATE TABLE myschema.t1 (i INTEGER);
DROP SCHEMA myschema CASCADE;
```

The following dependencies are tracked and thus will raise an error if the user tries to drop the depending object without the CASCADE modifier.

Depending object type	Dependent object type
SCHEMA	FUNCTION
SCHEMA	MACRO TABLE
SCHEMA	MACRO
SCHEMA	SCHEMA
SCHEMA	SEQUENCE
SCHEMA	TABLE
SCHEMA	TYPE
SCHEMA	VIEW

Limitations

Dependencies on Views

Currently, dependencies are not tracked for views. For example, if a view is created that references a table and the table is dropped, then the view will be in an invalid state:

```
CREATE TABLE tbl (i INTEGER);
CREATE VIEW view1 AS
    SELECT i FROM tbl;
DROP TABLE tbl RESTRICT;
SELECT * FROM view1;
```

This returns the following error message:

```
Catalog Error:
Table with name tbl does not exist!
```

Limitations on Reclaiming Disk Space

Running DROP TABLE should free the memory used by the table, but not always disk space. Even if disk space does not decrease, the free blocks will be marked as `free`. For example, if we have a 2 GB file and we drop a 1 GB table, the file might still be 2 GB, but it should have 1 GB of free blocks in it. To check this, use the following PRAGMA and check the number of `free_blocks` in the output:

```
PRAGMA database_size;
```

For instructions on reclaiming space after dropping a table, refer to the "Reclaiming space" page.

EXPORT and IMPORT DATABASE Statements

The EXPORT DATABASE command allows you to export the contents of the database to a specific directory. The IMPORT DATABASE command allows you to then read the contents again.

Examples

Export the database to the target directory 'target_directory' as CSV files:

```
EXPORT DATABASE 'target_directory';
```

Export to directory 'target_directory', using the given options for the CSV serialization:

```
EXPORT DATABASE 'target_directory' (FORMAT csv, DELIMITER '|');
```

Export to directory 'target_directory', tables serialized as Parquet:

```
EXPORT DATABASE 'target_directory' (FORMAT parquet);
```

Export to directory 'target_directory', tables serialized as Parquet, compressed with Zstd, with a row_group_size of 100,000:

```
EXPORT DATABASE 'target_directory' (
    FORMAT parquet,
    COMPRESSION zstd,
    ROW_GROUP_SIZE 100_000
);
```

Reload the database again:

```
IMPORT DATABASE 'source_directory';
```

Alternatively, use a PRAGMA:

```
PRAGMA import_database('source_directory');
```

For details regarding the writing of Parquet files, see the Parquet Files page in the Data Import section and the COPY Statement page.

EXPORT DATABASE

The `EXPORT DATABASE` command exports the full contents of the database – including schema information, tables, views and sequences – to a specific directory that can then be loaded again. The created directory will be structured as follows:

```
target_directory/schema.sql
target_directory/load.sql
target_directory/t_1.csv
...
target_directory/t_n.csv
```

The `schema.sql` file contains the schema statements that are found in the database. It contains any `CREATE SCHEMA`, `CREATE TABLE`, `CREATE VIEW` and `CREATE SEQUENCE` commands that are necessary to re-construct the database.

The `load.sql` file contains a set of `COPY` statements that can be used to read the data from the CSV files again. The file contains a single `COPY` statement for every table found in the schema.

Syntax

IMPORT DATABASE

The database can be reloaded by using the `IMPORT DATABASE` command again, or manually by running `schema.sql` followed by `load.sql` to re-load the data.

> `IMPORT DATABASE` expects to import into a fresh database. `schema.sql` uses plain `CREATE` statements (without `OR REPLACE` or `IF NOT EXISTS`), so importing into a database that already contains any of the exported objects – for example a user-defined type – fails with a "already exists" error. Import into an empty database.

Syntax

INSERT Statement

The `INSERT` statement inserts new data into a table.

Examples

Insert the values 1, 2, 3 into `tbl`:

```
INSERT INTO tbl
    VALUES (1), (2), (3);
```

Insert the result of a query into a table:

```
INSERT INTO tbl
    SELECT * FROM other_tbl;
```

Insert values into the `i` column, inserting the default value into other columns:

```
INSERT INTO tbl (i)
    VALUES (1), (2), (3);
```

Explicitly insert the default value into a column:

```
INSERT INTO tbl (i)
    VALUES (1), (DEFAULT), (3);
```

Assuming `tbl` has a primary key/unique constraint, do nothing on conflict:

```
INSERT OR IGNORE INTO tbl (i)
    VALUES (1);
```

Or update the table with the new values instead:

```
INSERT OR REPLACE INTO tbl (i)
    VALUES (1);
```

Syntax

`INSERT INTO` inserts new rows into a table. One can insert one or more rows specified by value expressions, or zero or more rows resulting from a query.

Insert Column Order

It's possible to provide an optional insert column order, this can either be `BY POSITION` (the default) or `BY NAME`. Each column not present in the explicit or implicit column list will be filled with a default value, either its declared default value or `NULL` if there is none.

If the expression for any column is not of the correct data type, automatic type conversion will be attempted.

`INSERT INTO ... [BY POSITION]`

The order that values are inserted into the columns of the table is determined by the order that the columns were declared in. That is, the values supplied by the `VALUES` clause or query are associated with the column list left-to-right. This is the default option, that can be explicitly specified using the `BY POSITION` option. For example:

```
CREATE TABLE tbl (a INTEGER, b INTEGER);
INSERT INTO tbl
    VALUES (5, 42);
```

Specifying `BY POSITION` is optional and is equivalent to the default behavior:

```
INSERT INTO tbl
    BY POSITION
    VALUES (5, 42);
```

To use a different order, column names can be provided as part of the target, for example:

```
CREATE TABLE tbl (a INTEGER, b INTEGER);
INSERT INTO tbl (b, a)
    VALUES (5, 42);
```

Adding `BY POSITION` results in the same behavior:

```
INSERT INTO tbl
    BY POSITION (b, a)
    VALUES (5, 42);
```

This will insert 5 into b and 42 into a.

`INSERT INTO ... BY NAME`

Using the `BY NAME` modifier, the names of the column list of the `SELECT` statement are matched against the column names of the table to determine the order that values should be inserted into the table. This allows inserting even in cases when the order of the columns in the table differs from the order of the values in the `SELECT` statement or certain columns are missing.

For example:

```
CREATE TABLE tbl (a INTEGER, b INTEGER);
INSERT INTO tbl BY NAME (SELECT 42 AS b, 32 AS a);
INSERT INTO tbl BY NAME (SELECT 22 AS b);
SELECT * FROM tbl;
```

a	b
32	42
NULL	22

It's important to note that when using `INSERT INTO ... BY NAME`, the column names specified in the `SELECT` statement must match the column names in the table. If a column name is misspelled or does not exist in the table, an error will occur. Columns that are missing from the `SELECT` statement will be filled with the default value.

`ON CONFLICT` Clause

An `ON CONFLICT` clause can be used to perform a certain action on conflicts that arise from `UNIQUE` or `PRIMARY KEY` constraints. An example for such a conflict is shown in the following example:

```
CREATE TABLE tbl (i INTEGER PRIMARY KEY, j INTEGER);
INSERT INTO tbl
    VALUES (1, 42);
INSERT INTO tbl
    VALUES (1, 84);
```

This raises an error:

```
Constraint Error:
Duplicate key "i: 1" violates primary key constraint.
```

The table will contain the row that was first inserted:

```
SELECT * FROM tbl;
```

i	j
1	42

These error messages can be avoided by explicitly handling conflicts. DuckDB supports two such clauses: `ON CONFLICT DO NOTHING` and `ON CONFLICT DO UPDATE SET ...`.

`DO NOTHING` Clause

The `DO NOTHING` clause causes the error(s) to be ignored, and the values are not inserted or updated. For example:

```
CREATE TABLE tbl (i INTEGER PRIMARY KEY, j INTEGER);
INSERT INTO tbl
    VALUES (1, 42);
INSERT INTO tbl
    VALUES (1, 84)
    ON CONFLICT DO NOTHING;
```

These statements finish successfully and leave the table with the row `<i: 1, j: 42>`.

`INSERT OR IGNORE INTO` The `INSERT OR IGNORE INTO ...` statement is a shorter syntax alternative to `INSERT INTO ... ON CONFLICT DO NOTHING`. For example, the following statements are equivalent:

```
INSERT OR IGNORE INTO tbl
    VALUES (1, 84);
INSERT INTO tbl
    VALUES (1, 84) ON CONFLICT DO NOTHING;
```

`DO UPDATE` Clause (Upsert)

The `DO UPDATE` clause causes the `INSERT` to turn into an `UPDATE` on the conflicting row(s) instead. The `SET` expressions that follow determine how these rows are updated. The expressions can use the special virtual table `EXCLUDED`, which contains the conflicting values for the row. Optionally you can provide an additional `WHERE` clause that can exclude certain rows from the update. The conflicts that don't meet this condition are ignored instead.

Because we need a way to refer to both the **to-be-inserted** tuple and the **existing** tuple, we introduce the special `EXCLUDED` qualifier. When the `EXCLUDED` qualifier is provided, the reference refers to the **to-be-inserted** tuple, otherwise, it refers to the **existing** tuple. This special qualifier can be used within the `WHERE` clauses and `SET` expressions of the `ON CONFLICT` clause.

```
CREATE TABLE tbl (i INTEGER PRIMARY KEY, j INTEGER);
INSERT INTO tbl VALUES (1, 42);
INSERT INTO tbl VALUES (1, 52), (1, 62) ON CONFLICT DO UPDATE SET j = EXCLUDED.j;
```

Examples An example using `DO UPDATE` is the following:

```
CREATE TABLE tbl (i INTEGER PRIMARY KEY, j INTEGER);
INSERT INTO tbl
    VALUES (1, 42);
INSERT INTO tbl
    VALUES (1, 84)
    ON CONFLICT DO UPDATE SET j = EXCLUDED.j;
SELECT * FROM tbl;
```

i	j
1	84

Rearranging columns and using BY NAME is also possible:

```
CREATE TABLE tbl (i INTEGER PRIMARY KEY, j INTEGER);
INSERT INTO tbl
    VALUES (1, 42);
INSERT INTO tbl (j, i)
    VALUES (168, 1)
    ON CONFLICT DO UPDATE SET j = EXCLUDED.j;
INSERT INTO tbl
    BY NAME (SELECT 1 AS i, 336 AS j)
    ON CONFLICT DO UPDATE SET j = EXCLUDED.j;
SELECT * FROM tbl;
```

i	j
1	336

`INSERT OR REPLACE INTO` The `INSERT OR REPLACE INTO ...` statement is a shorter syntax alternative to `INSERT INTO ... DO UPDATE SET c1 = EXCLUDED.c1, c2 = EXCLUDED.c2, ...`. That is, it updates every column of the **existing** row to the new values of the **to-be-inserted** row. For example, given the following input table:

```
CREATE TABLE tbl (i INTEGER PRIMARY KEY, j INTEGER);
INSERT INTO tbl
    VALUES (1, 42);
```

These statements are equivalent:

```
INSERT OR REPLACE INTO tbl
    VALUES (1, 84);
INSERT INTO tbl
    VALUES (1, 84)
    ON CONFLICT DO UPDATE SET j = EXCLUDED.j;
INSERT INTO tbl (j, i)
    VALUES (84, 1)
    ON CONFLICT DO UPDATE SET j = EXCLUDED.j;
INSERT INTO tbl BY NAME
    (SELECT 84 AS j, 1 AS i)
    ON CONFLICT DO UPDATE SET j = EXCLUDED.j;
```

Limitations When the `ON CONFLICT ... DO UPDATE` clause is used and a conflict occurs, DuckDB internally assigns `NULL` values to the row's columns that are unaffected by the conflict, then re-assigns their values. If the affected columns use a `NOT NULL` constraint, this will trigger a `NOT NULL constraint failed` error. For example:

```
CREATE TABLE t1 (id INTEGER PRIMARY KEY, val1 DOUBLE, val2 DOUBLE NOT NULL);
CREATE TABLE t2 (id INTEGER PRIMARY KEY, val1 DOUBLE);
INSERT INTO t1
    VALUES (1, 2, 3);
INSERT INTO t2
    VALUES (1, 5);

INSERT INTO t1 BY NAME (SELECT id, val1 FROM t2)
    ON CONFLICT DO UPDATE
    SET val1 = EXCLUDED.val1;
```

This fails with the following error:

```
Constraint Error:
NOT NULL constraint failed: t1.val2
```

Composite Primary Key When multiple columns need to be part of the uniqueness constraint, use a single `PRIMARY KEY` clause including all relevant columns:

```
CREATE TABLE t1 (id1 INTEGER, id2 INTEGER, val1 DOUBLE, PRIMARY KEY (id1, id2));
INSERT OR REPLACE INTO t1
    VALUES (1, 2, 3);
INSERT OR REPLACE INTO t1
    VALUES (1, 2, 4);
```

Defining a Conflict Target

A conflict target may be provided as `ON CONFLICT (conflict_target)`. This is a group of columns that an index or uniqueness/key constraint is defined on. If the conflict target is omitted, the `PRIMARY KEY` constraint(s) on the table are targeted.

Specifying a conflict target is optional unless using a `DO UPDATE` and there are multiple unique/primary key constraints on the table.

```
CREATE TABLE tbl (i INTEGER PRIMARY KEY, j INTEGER UNIQUE, k INTEGER);
INSERT INTO tbl
    VALUES (1, 20, 300);
SELECT * FROM tbl;
```

i	j	k
1	20	300

```
INSERT INTO tbl
    VALUES (1, 40, 700)
    ON CONFLICT (i) DO UPDATE SET k = 2 * EXCLUDED.k;
```

i	j	k
1	20	1400

```
INSERT INTO tbl
    VALUES (1, 20, 900)
    ON CONFLICT (j) DO UPDATE SET k = 5 * EXCLUDED.k;
```

i	j	k
1	20	4500

When a conflict target is provided, you can further filter this with a `WHERE` clause, that should be met by all conflicts.

```
INSERT INTO tbl
    VALUES (1, 40, 700)
    ON CONFLICT (i) DO UPDATE SET k = 2 * EXCLUDED.k WHERE k < 100;
```

`RETURNING` Clause

The `RETURNING` clause may be used to return the contents of the rows that were inserted. This can be useful if some columns are calculated upon insert. For example, if the table contains an automatically incrementing primary key, then the `RETURNING` clause will include the automatically created primary key. This is also useful in the case of generated columns.

Some or all columns can be explicitly chosen to be returned and they may optionally be renamed using aliases. Arbitrary non-aggregating expressions may also be returned instead of simply returning a column. All columns can be returned using the `*` expression, and columns or expressions can be returned in addition to all columns returned by the `*`.

For example:

```
CREATE TABLE t1 (i INTEGER);
INSERT INTO t1
    SELECT 42
    RETURNING *;
```

i
42

A more complex example that includes an expression in the `RETURNING` clause:

```
CREATE TABLE t2 (i INTEGER, j INTEGER);
INSERT INTO t2
    SELECT 2 AS i, 3 AS j
    RETURNING *, i * j AS i_times_j;
```

i	j	i_times_j
2	3	6

The next example shows a situation where the `RETURNING` clause is more helpful. First, a table is created with a primary key column. Then a sequence is created to allow for that primary key to be incremented as new rows are inserted. When we insert into the table, we do not already know the values generated by the sequence, so it is valuable to return them. For additional information, see the CREATE SEQUENCE page.

```
CREATE TABLE t3 (i INTEGER PRIMARY KEY, j INTEGER);
CREATE SEQUENCE 't3_key';
INSERT INTO t3
    SELECT nextval('t3_key') AS i, 42 AS j
    UNION ALL
    SELECT nextval('t3_key') AS i, 43 AS j
    RETURNING *;
```

i	j
1	42
2	43

LOAD / INSTALL Statements

`INSTALL`

The `INSTALL` statement downloads an extension so it can be loaded into a DuckDB session.

Examples

Install the `httpfs` extension:

```
INSTALL httpfs;
```

Install the h3 community extension:

```
INSTALL h3 FROM community;
```

Syntax

LOAD

The LOAD statement loads an installed DuckDB extension into the current session.

Examples

Load the `httpfs` extension:

```
LOAD httpfs;
```

Load the `spatial` extension:

```
LOAD spatial;
```

Syntax

MERGE INTO Statement

The `MERGE INTO` statement is an alternative to `INSERT INTO ... ON CONFLICT` that doesn't need a primary key since it allows for a custom match condition. This is a very useful alternative for upserting use cases (`INSERT` + `UPDATE`) when the destination table does not have a primary key constraint.

Examples

First, let's create a simple table.

```
CREATE TABLE people (id INTEGER, name VARCHAR, salary FLOAT);
INSERT INTO people VALUES (1, 'John', 92_000.0), (2, 'Anna', 100_000.0);
```

The simplest upsert would be to use a whole row in the `USING` clause. This way, if there is a match, the row can be updated to the new row without further instuctions (`WHEN MATCHED THEN UPDATE`), and when there is no match, the row can be trivially inserted into the table (`WHEN NOT MATCHED THEN INSERT`).

```
MERGE INTO people
    USING (
        SELECT
            unnest([3, 1]) AS id,
            unnest(['Sarah', 'John']) AS name,
            unnest([95_000.0, 105_000.0]) AS salary
    ) AS upserts
    ON (upserts.id = people.id)
    WHEN MATCHED THEN UPDATE
    WHEN NOT MATCHED THEN INSERT;

FROM people
ORDER BY id;
```

id	name	salary
1	John	105000.0
2	Anna	100000.0
3	Sarah	95000.0

In the previous example we are updating the whole row if `id` matches. However, it is also a common pattern to receive a *change set* with some keys and the changed value. This is a good use for `SET`. If the match condition uses a column that has the same name in the source and destination, the keyword `USING` can be used in the match condition.

```
MERGE INTO people
    USING (
        SELECT
            1 AS id,
            98_000.0 AS salary
    ) AS salary_updates
    USING (id)
    WHEN MATCHED THEN UPDATE SET salary = salary_updates.salary;

FROM people
ORDER BY id;
```

id	name	salary
1	John	98000.0
2	Anna	100000.0
3	Sarah	95000.0

Another common pattern is to receive a *delete set* of rows, which may only contain ids of rows to be deleted.

```
MERGE INTO people
    USING (
        SELECT
            1 AS id,
    ) AS deletes
    USING (id)
    WHEN MATCHED THEN DELETE;

FROM people
ORDER BY id;
```

id	name	salary
2	Anna	100000.0
3	Sarah	95000.0

`MERGE INTO` also supports more complex conditions, for example, for a given *delete set* we can decide to only remove rows that contain a `salary` bigger or equal than a certain amount.

```
MERGE INTO people
    USING (
        SELECT
```

```
            unnest([3, 2]) AS id,
    ) AS deletes
    USING (id)
    WHEN MATCHED AND people.salary >= 100_000.0 THEN DELETE;

FROM people
ORDER BY id;
```

id	name	salary
3	Sarah	95000.0

If needed, DuckDB also supports multiple `UPDATE` and `DELETE` conditions. The `RETURNING` clause can be used to indicate which rows were affected by the `MERGE` statement.

```
-- Let's get John back in!
INSERT INTO people VALUES (1, 'John', 105_000.0);

MERGE INTO people
    USING (
        SELECT
            unnest([3, 1]) AS id,
            unnest([89_000.0, 70_000.0]) AS salary
    ) AS upserts
    USING (id)
    WHEN MATCHED AND people.salary < 100_000.0 THEN UPDATE SET salary = upserts.salary
    -- Second update or delete condition
    WHEN MATCHED AND people.salary > 100_000.0 THEN DELETE
    WHEN NOT MATCHED THEN INSERT BY NAME
    RETURNING merge_action, *;
```

merge_action	id	name	salary
UPDATE	3	Sarah	89000.0
DELETE	1	John	105000.0

In some cases, you may want to perform a different action specifically if the source doesn't meet a condition. For example, if we expect that data that is not present on the source shouldn't be present in the target:

```
CREATE TABLE target AS
    SELECT unnest([1,2]) AS id;

MERGE INTO target
    USING (SELECT 1 AS id) source
    USING (id)
    WHEN MATCHED THEN UPDATE
    WHEN NOT MATCHED BY SOURCE THEN DELETE
    RETURNING merge_action, *;
```

merge_action	id
UPDATE	1
DELETE	2

There is also the possibility of specifying `WHEN NOT MATCHED BY TARGET`. However, the behavior is, as you may expect, the same as `WHEN NOT MATCHED` since by default when specifying conditions, we look at the target.

Syntax

PIVOT Statement

The PIVOT statement allows distinct values within a column to be separated into their own columns. The values within those new columns are calculated using an aggregate function on the subset of rows that match each distinct value.

DuckDB implements both the SQL Standard PIVOT syntax and a simplified PIVOT syntax that automatically detects the columns to create while pivoting. PIVOT_WIDER may also be used in place of the PIVOT keyword.

For details on how the PIVOT statement is implemented, see the Pivot Internals site.

> The UNPIVOT statement is the inverse of the PIVOT statement.

Simplified PIVOT Syntax

The full syntax diagram is below, but the simplified PIVOT syntax can be summarized using spreadsheet pivot table naming conventions as:

```
PIVOT <dataset>
ON <columns>
USING <values>
GROUP BY <rows>
ORDER BY <columns_with_order_directions>
LIMIT <number_of_rows>;
```

The ON, USING, and GROUP BY clauses are each optional, but they may not all be omitted.

Example Data

All examples use the dataset produced by the queries below:

```
CREATE TABLE cities (
    country VARCHAR, name VARCHAR, year INTEGER, population INTEGER
);
INSERT INTO cities VALUES
    ('NL', 'Amsterdam', 2000, 1005),
    ('NL', 'Amsterdam', 2010, 1065),
    ('NL', 'Amsterdam', 2020, 1158),
    ('US', 'Seattle', 2000, 564),
    ('US', 'Seattle', 2010, 608),
    ('US', 'Seattle', 2020, 738),
    ('US', 'New York City', 2000, 8015),
    ('US', 'New York City', 2010, 8175),
    ('US', 'New York City', 2020, 8772);

SELECT *
FROM cities;
```

country	name	year	population
NL	Amsterdam	2000	1005
NL	Amsterdam	2010	1065
NL	Amsterdam	2020	1158
US	Seattle	2000	564

country	name	year	population
US	Seattle	2010	608
US	Seattle	2020	738
US	New York City	2000	8015
US	New York City	2010	8175
US	New York City	2020	8772

`PIVOT ON` and `USING`

Use the `PIVOT` statement below to create a separate column for each year and calculate the total population in each. The `ON` clause specifies which column(s) to split into separate columns. It is equivalent to the columns parameter in a spreadsheet pivot table.

The `USING` clause determines how to aggregate the values that are split into separate columns. This is equivalent to the values parameter in a spreadsheet pivot table. If the `USING` clause is not included, it defaults to `count(*)`.

```
PIVOT cities
ON year
USING sum(population);
```

country	name	2000	2010	2020
NL	Amsterdam	1005	1065	1158
US	Seattle	564	608	738
US	New York City	8015	8175	8772

In the above example, the `sum` aggregate is always operating on a single value. If we only want to change the orientation of how the data is displayed without aggregating, use the `first` aggregate function. In this example, we are pivoting numeric values, but the `first` function works very well for pivoting out a text column. (This is something that is difficult to do in a spreadsheet pivot table, but easy in DuckDB!)

This query produces a result that is identical to the one above:

```
PIVOT cities
ON year
USING first(population);
```

> **Note.** The SQL syntax permits `FILTER` clauses with aggregate functions in the `USING` clause. In DuckDB, the `PIVOT` statement currently does not support these and they are silently ignored.

`PIVOT ON`, `USING`, and `GROUP BY`

By default, the `PIVOT` statement retains all columns not specified in the `ON` or `USING` clauses. To include only certain columns and further aggregate, specify columns in the `GROUP BY` clause. This is equivalent to the rows parameter of a spreadsheet pivot table.

In the below example, the `name` column is no longer included in the output, and the data is aggregated up to the `country` level.

```
PIVOT cities
ON year
USING sum(population)
GROUP BY country;
```

country	2000	2010	2020
NL	1005	1065	1158
US	8579	8783	9510

`IN` Filter for `ON` Clause

To only create a separate column for specific values within a column in the `ON` clause, use an optional `IN` expression. Let's say for example that we wanted to forget about the year 2020 for no particular reason...

```
PIVOT cities
ON year IN (2000, 2010)
USING sum(population)
GROUP BY country;
```

country	2000	2010
NL	1005	1065
US	8579	8783

Multiple Expressions per Clause

Multiple columns can be specified in the `ON` and `GROUP BY` clauses, and multiple aggregate expressions can be included in the `USING` clause.

Multiple `ON` Columns and `ON` Expressions Multiple columns can be pivoted out into their own columns. DuckDB will find the distinct values in each `ON` clause column and create one new column for all combinations of those values (a Cartesian product).

In the below example, all combinations of unique countries and unique cities receive their own column. Some combinations may not be present in the underlying data, so those columns are populated with `NULL` values.

```
PIVOT cities
ON country, name
USING sum(population);
```

year	NL_Amsterdam	NL_New York City	NL_Seattle	US_Amsterdam	US_New York City	US_Seattle
2000	1005	NULL	NULL	NULL	8015	564
2010	1065	NULL	NULL	NULL	8175	608
2020	1158	NULL	NULL	NULL	8772	738

To pivot only the combinations of values that are present in the underlying data, use an expression in the `ON` clause. Multiple expressions and/or columns may be provided.

Here, `country` and `name` are concatenated together and the resulting concatenations each receive their own column. Any arbitrary non-aggregating expression may be used. In this case, concatenating with an underscore is used to imitate the naming convention the `PIVOT` clause uses when multiple `ON` columns are provided (like in the prior example).

```
PIVOT cities
ON country || '_' || name
USING sum(population);
```

year	NL_Amsterdam	US_New York City	US_Seattle
2000	1005	8015	564
2010	1065	8175	608
2020	1158	8772	738

Multiple `USING` Expressions An alias may also be included for each expression in the `USING` clause. It will be appended to the generated column names after an underscore (`_`). This makes the column naming convention much cleaner when multiple expressions are included in the `USING` clause.

In this example, both the `sum` and `max` of the population column are calculated for each year and are split into separate columns.

```
PIVOT cities
ON year
USING sum(population) AS total, max(population) AS max
GROUP BY country;
```

country	2000_total	2000_max	2010_total	2010_max	2020_total	2020_max
US	8579	8015	8783	8175	9510	8772
NL	1005	1005	1065	1065	1158	1158

Multiple `GROUP BY` Columns Multiple `GROUP BY` columns may also be provided. Note that column names must be used rather than column positions (1, 2, etc.), and that expressions are not supported in the `GROUP BY` clause.

```
PIVOT cities
ON year
USING sum(population)
GROUP BY country, name;
```

country	name	2000	2010	2020
NL	Amsterdam	1005	1065	1158
US	Seattle	564	608	738
US	New York City	8015	8175	8772

Using `PIVOT` within a `SELECT` Statement

The `PIVOT` statement may be included within a `SELECT` statement as a CTE (a Common Table Expression, or `WITH` clause), or a subquery. This allows for a `PIVOT` to be used alongside other SQL logic, as well as for multiple `PIVOT`s to be used in one query.

No `SELECT` is needed within the CTE, the `PIVOT` keyword can be thought of as taking its place.

```
WITH pivot_alias AS (
    PIVOT cities
    ON year
    USING sum(population)
    GROUP BY country
)
SELECT * FROM pivot_alias;
```

A `PIVOT` may be used in a subquery and must be wrapped in parentheses. Note that this behavior is different than the SQL Standard Pivot, as illustrated in subsequent examples.

```
SELECT *
FROM (
    PIVOT cities
    ON year
    USING sum(population)
    GROUP BY country
) pivot_alias;
```

Multiple PIVOT Statements

Each PIVOT can be treated as if it were a SELECT node, so they can be joined together or manipulated in other ways.

For example, if two PIVOT statements share the same GROUP BY expression, they can be joined together using the columns in the GROUP BY clause into a wider pivot.

```
SELECT *
FROM (PIVOT cities ON year USING sum(population) GROUP BY country) year_pivot
JOIN (PIVOT cities ON name USING sum(population) GROUP BY country) name_pivot
USING (country);
```

country	2000	2010	2020	Amsterdam	New York City	Seattle
NL	1005	1065	1158	3228	NULL	NULL
US	8579	8783	9510	NULL	24962	1910

Simplified PIVOT Full Syntax Diagram

Below is the full syntax diagram of the PIVOT statement.

SQL Standard PIVOT Syntax

The full syntax diagram is below, but the SQL Standard PIVOT syntax can be summarized as:

```
SELECT *
FROM <dataset>
PIVOT (
    <values>
    FOR
        <column_1> IN (<in_list>)
        <column_2> IN (<in_list>)
        ...
    GROUP BY <rows>
);
```

Unlike the simplified syntax, the IN clause must be specified for each column to be pivoted. If you are interested in dynamic pivoting, the simplified syntax is recommended.

Note that no commas separate the expressions in the FOR clause, but that value and GROUP BY expressions must be comma-separated!

Examples

This example uses a single value expression, a single column expression, and a single row expression:

```
SELECT *
FROM cities
PIVOT (
    sum(population)
    FOR
        year IN (2000, 2010, 2020)
    GROUP BY country
);
```

country	2000	2010	2020
NL	1005	1065	1158
US	8579	8783	9510

This example is somewhat contrived, but serves as an example of using multiple value expressions and multiple columns in the FOR clause.

```
SELECT *
FROM cities
PIVOT (
    sum(population) AS total,
    count(population) AS count
    FOR
        year IN (2000, 2010)
        country IN ('NL', 'US')
);
```

name	2000_NL_total	2000_NL_count	2000_US_total	2000_US_count	2010_NL_total	2010_NL_count	2010_US_total	2010_US_count
Amsterdam	1005	1	NULL	0	1065	1	NULL	0
Seattle	NULL	0	564	1	NULL	0	608	1
New York City	NULL	0	8015	1	NULL	0	8175	1

SQL Standard PIVOT Full Syntax Diagram

Below is the full syntax diagram of the SQL Standard version of the PIVOT statement.

Limitations

PIVOT currently only accepts an aggregate function, expressions are not allowed. For example, the following query attempts to get the population as the number of people instead of thousands of people (i.e., instead of 564, get 564000):

```
PIVOT cities
ON year
USING sum(population) * 1000;
```

However, it fails with the following error:

```
Catalog Error:
* is not an aggregate function
```

To work around this limitation, perform the PIVOT with the aggregation only, then use the COLUMNS expression:

```
SELECT country, name, 1000 * COLUMNS(* EXCLUDE (country, name))
FROM (
    PIVOT cities
    ON year
    USING sum(population)
);
```

Profiling Queries

DuckDB supports profiling queries via the `EXPLAIN` and `EXPLAIN ANALYZE` statements.

`EXPLAIN`

To see the query plan of a query without executing it, run:

```
EXPLAIN <query>;
```

The output of `EXPLAIN` contains the estimated cardinalities for each operator.

`EXPLAIN ANALYZE`

To profile a query, run:

```
EXPLAIN ANALYZE <query>;
```

The `EXPLAIN ANALYZE` statement runs the query, and shows the actual cardinalities for each operator, as well as the cumulative wall-clock time spent in each operator.

SELECT Statement

The `SELECT` statement retrieves rows from the database.

Examples

Select all columns from the table `tbl`:

```
SELECT * FROM tbl;
```

Select the rows from `tbl`:

```
SELECT j FROM tbl WHERE i = 3;
```

Perform an aggregate grouped by the column `i`:

```
SELECT i, sum(j) FROM tbl GROUP BY i;
```

Select only the top 3 rows from the `tbl`:

```
SELECT * FROM tbl ORDER BY i DESC LIMIT 3;
```

Join two tables together using the `USING` clause:

```
SELECT * FROM t1 JOIN t2 USING (a, b);
```

Use column indexes to select the first and third column from the table `tbl`:

```
SELECT #1, #3 FROM tbl;
```

Select all unique cities from the addresses table:

```
SELECT DISTINCT city FROM addresses;
```

Return a STRUCT by using a row variable:

```
SELECT d
FROM (SELECT 1 AS a, 2 AS b) d;
```

Syntax

The SELECT statement retrieves rows from the database. The canonical order of a SELECT statement is as follows, with less common clauses being indented:

```
SELECT <select_list>
FROM <tables>
    USING SAMPLE <sample_expression>
WHERE <condition>
GROUP BY <groups>
HAVING <group_filter>
    WINDOW <window_expression>
    QUALIFY <qualify_filter>
ORDER BY <order_expression>
LIMIT <n>;
```

Optionally, the SELECT statement can be prefixed with a WITH clause.

As the SELECT statement is so complex, we have split up the syntax diagrams into several parts. The full syntax diagram can be found at the bottom of the page.

SELECT Clause

The SELECT clause specifies the list of columns that will be returned by the query. While it appears first in the clause, *logically* the expressions here are executed only at the end. The SELECT clause can contain arbitrary expressions that transform the output, as well as aggregates and window functions. The DISTINCT keyword ensures that only unique tuples are returned.

> Column names are case-insensitive. See the Rules for Case Sensitivity for more details.

FROM Clause

The FROM clause specifies the *source* of the data on which the remainder of the query should operate. Logically, the FROM clause is where the query starts execution. The FROM clause can contain a single table, a combination of multiple tables that are joined together, or another SELECT query inside a subquery node.

SAMPLE Clause

The SAMPLE clause allows you to run the query on a sample from the base table. This can significantly speed up processing of queries, at the expense of accuracy in the result. Samples can also be used to quickly see a snapshot of the data when exploring a dataset. The SAMPLE clause is applied right after anything in the FROM clause (i.e., after any joins, but before the where clause or any aggregates). See the Samples page for more information.

WHERE Clause

The WHERE clause specifies any filters to apply to the data. This allows you to select only a subset of the data in which you are interested. Logically the WHERE clause is applied immediately after the FROM clause.

GROUP BY and HAVING Clauses

The GROUP BY clause specifies which grouping columns should be used to perform any aggregations in the SELECT clause. If the GROUP BY clause is specified, the query is always an aggregate query, even if no aggregations are present in the SELECT clause.

WINDOW Clause

The WINDOW clause allows you to specify named windows that can be used within window functions. These are useful when you have multiple window functions, as they allow you to avoid repeating the same window clause.

QUALIFY Clause

The QUALIFY clause is used to filter the result of WINDOW functions.

ORDER BY, LIMIT and OFFSET Clauses

ORDER BY, LIMIT and OFFSET are output modifiers. Logically they are applied at the very end of the query. The ORDER BY clause sorts the rows on the sorting criteria in either ascending or descending order. The LIMIT clause restricts the amount of rows fetched, while the OFFSET clause indicates at which position to start reading the values.

VALUES List

A VALUES list is a set of values that is supplied instead of a SELECT statement.

Row IDs

For each table, the rowid pseudocolumn returns the row identifiers based on the physical storage.

```
CREATE TABLE t (id INTEGER, content VARCHAR);
INSERT INTO t VALUES (42, 'hello'), (43, 'world');
SELECT rowid, id, content FROM t;
```

rowid	id	content
0	42	hello
1	43	world

In the current storage, these identifiers are contiguous unsigned integers (0, 1, ...) if no rows were deleted. Deletions introduce gaps in the rowids which may be reclaimed later:

```
CREATE OR REPLACE TABLE t AS (FROM range(10) r(i));
DELETE FROM t WHERE i % 2 = 0;
SELECT rowid FROM t;
```

rowid
1
3
5

rowid
7
9

The `rowid` values are stable within a transaction.

> **Best practice.** It is strongly advised to avoid using rowids as identifiers.

> If there is a user-defined column named `rowid`, it shadows the `rowid` pseudocolumn.

Common Table Expressions

Full Syntax Diagram

Below is the full syntax diagram of the `SELECT` statement:

SET and RESET Statements

The `SET` statement modifies the provided DuckDB configuration option at the specified scope.

Examples

Update the `memory_limit` configuration value:

```
SET memory_limit = '10GB';
```

Configure the system to use `1` thread:

```
SET threads = 1;
```

Or use the `TO` keyword:

```
SET threads TO 1;
```

Change configuration option to default value:

```
RESET threads;
```

Retrieve configuration value:

```
SELECT current_setting('threads');
```

Set the default collation for the session:

```
SET SESSION default_collation = 'nocase';
```

Set a Global Variable

Set the default sort order globally:

```
SET GLOBAL sort_order = 'desc';
```

Set the default threads globally:

```
SET GLOBAL threads = 4;
```

Syntax

SET updates a DuckDB configuration option to the provided value.

RESET

The RESET statement changes the given DuckDB configuration option to the default value.

Scopes

Configuration options can have different scopes:

- GLOBAL: Configuration value is used (or reset) across the entire DuckDB instance.
- SESSION: Configuration value is used (or reset) only for the current session attached to a DuckDB instance.
- LOCAL: Not yet implemented.

When not specified, the default scope for the configuration option is used. For most options this is GLOBAL.

Configuration

See the Configuration page for the full list of configuration options.

SET VARIABLE and RESET VARIABLE Statements

DuckDB supports the definition of SQL-level variables using the SET VARIABLE and RESET VARIABLE statements.

Variable Scopes

DuckDB supports two levels of variable scopes:

Scope	Description
SESSION	Variables with a SESSION scope are local to you and only affect the current session.
GLOBAL	Variables with a GLOBAL scope are specific configuration option variables that affect the entire DuckDB instance and all sessions. For example, see Set a Global Variable.

SET VARIABLE

The SET VARIABLE statement assigns a value to a variable, which can be accessed using the getvariable call:

```
SET VARIABLE my_var = 30;
SELECT 20 + getvariable('my_var') AS total;
```

total
50

If SET VARIABLE is invoked on an existing variable, it will overwrite its value:

```
SET VARIABLE my_var = 30;
SET VARIABLE my_var = 100;
SELECT 20 + getvariable('my_var') AS total;
```

total
120

Variables can have different types:

```
SET VARIABLE my_date = DATE '2018-07-13';
SET VARIABLE my_string = 'Hello world';
SET VARIABLE my_map = MAP {'k1': 10, 'k2': 20};
```

Variables can also be assigned to results of queries:

```
-- write some CSV files
COPY (SELECT 42 AS a) TO 'test1.csv';
COPY (SELECT 84 AS a) TO 'test2.csv';

-- add a list of CSV files to a table
CREATE TABLE csv_files (file VARCHAR);
INSERT INTO csv_files VALUES ('test1.csv'), ('test2.csv');

-- initialize a variable with the list of csv files
SET VARIABLE list_of_files = (SELECT list(file) FROM csv_files);

-- read the CSV files
SELECT * FROM read_csv(getvariable('list_of_files'), filename := True);
```

a	filename
42	test.csv
84	test2.csv

If a variable is not set, the `getvariable` function returns `NULL`:

```
SELECT getvariable('undefined_var') AS result;
```

result
NULL

The `getvariable` function can also be used in a COLUMNS expression:

```
SET VARIABLE column_to_exclude = 'col1';
CREATE TABLE tbl AS SELECT 12 AS col0, 34 AS col1, 56 AS col2;
SELECT COLUMNS(c -> c != getvariable('column_to_exclude')) FROM tbl;
```

col0	col2
12	56

Syntax

`RESET VARIABLE`

The `RESET VARIABLE` statement unsets a variable.

```
SET VARIABLE my_var = 30;
RESET VARIABLE my_var;
SELECT getvariable('my_var') AS my_var;
```

my_var
NULL

Syntax

SHOW, SHOW DATABASES, and SHOW SCHEMAS Statements

SHOW Statement

The SHOW statement is an alias for `DESCRIBE`. It shows the schema of a table, view or query.

SHOW DATABASES Statement

The `SHOW DATABASES` statement shows a list of all attached databases:

```
ATTACH 'my.duckdb' AS my_database;
SHOW DATABASES;
```

database_name
memory
my_database

```
DETACH my_database;
SHOW DATABASES;
```

database_name
memory

SHOW SCHEMAS Statement

> This statement was introduced in DuckDB v1.5.

The `SHOW SCHEMAS` statement shows a list of all schemas across non-internal databases:

```
SHOW SCHEMAS;
```

database_name	schema_name	current
memory	main	true
memory	pg_catalog	false
memory	information_schema	false

The `current` column indicates which schema is the default schema (set via the USE statement).

SUMMARIZE Statement

The SUMMARIZE statement returns summary statistics for a table, view or a query.

Usage

```
SUMMARIZE tbl;
```

To summarize a query, prepend SUMMARIZE to a query.

```
SUMMARIZE SELECT * FROM tbl;
```

See Also

For more examples, see the guide on SUMMARIZE.

Transaction Management

DuckDB supports ACID database transactions. Transactions provide isolation, i.e., changes made by a transaction are not visible from concurrent transactions until it is committed. A transaction can also be aborted, which discards any changes it made so far.

Statements

DuckDB provides the following statements for transaction management.

Starting a Transaction

To start a transaction, run:

```
BEGIN TRANSACTION;
```

Committing a Transaction

You can commit a transaction to make it visible to other transactions and to write it to persistent storage (if using DuckDB in persistent mode). To commit a transaction, run:

```
COMMIT;
```

If you are not in an active transaction, the COMMIT statement will fail.

Rolling Back a Transaction

You can abort a transaction. This operation, also known as rolling back, will discard any changes the transaction made to the database. To abort a transaction, run:

```
ROLLBACK;
```

You can also use the abort command, which has an identical behavior:

```
ABORT;
```

If you are not in an active transaction, the ROLLBACK and ABORT statements will fail.

Multi-Statement Transactions

When multiple SQL statements are submitted together (e.g., separated by semicolons), they are executed within a single implicit transaction. If any statement fails, all preceding statements in the batch are rolled back. This also applies to PRAGMA commands that decompose into multiple internal operations, such as `COPY FROM DATABASE`.

Isolation Level

DuckDB's concurrency model guarantees snapshot isolation. Transactions that violate this isolation level are aborted.

Using PostgreSQL's transaction isolation levels, DuckDB guarantees *repeatable reads*.

Example

We illustrate the use of transactions through a simple example.

```
CREATE TABLE person (name VARCHAR, age BIGINT);

BEGIN TRANSACTION;
INSERT INTO person VALUES ('Ada', 52);
COMMIT;

BEGIN TRANSACTION;
DELETE FROM person WHERE name = 'Ada';
INSERT INTO person VALUES ('Bruce', 39);
ROLLBACK;

SELECT * FROM person;
```

The first transaction (inserting “Ada”) was committed but the second (deleting “Ada” and inserting “Bruce”) was aborted. Therefore, the resulting table will only contain `<'Ada', 52>`.

UNPIVOT Statement

The `UNPIVOT` statement allows multiple columns to be stacked into fewer columns. In the basic case, multiple columns are stacked into two columns: a `NAME` column (which contains the name of the source column) and a `VALUE` column (which contains the value from the source column).

DuckDB implements both the SQL Standard `UNPIVOT` syntax and a simplified `UNPIVOT` syntax. Both can utilize a `COLUMNS` expression to automatically detect the columns to unpivot. `PIVOT_LONGER` may also be used in place of the `UNPIVOT` keyword.

For details on how the `UNPIVOT` statement is implemented, see the Pivot Internals site.

> The PIVOT statement is the inverse of the UNPIVOT statement.

Simplified UNPIVOT Syntax

The full syntax diagram is below, but the simplified UNPIVOT syntax can be summarized using spreadsheet pivot table naming conventions as:

```
UNPIVOT <dataset>
ON <column(s)>
INTO
    NAME <name_column_name>
    VALUE <value_column_name(s)>
ORDER BY <column(s)_with_order_direction(s)>
LIMIT <number_of_rows>;
```

Example Data

All examples use the dataset produced by the queries below:

```
CREATE OR REPLACE TABLE monthly_sales
    (empid INTEGER, dept TEXT, Jan INTEGER, Feb INTEGER, Mar INTEGER, Apr INTEGER, May INTEGER, Jun
INTEGER);
INSERT INTO monthly_sales VALUES
    (1, 'electronics', 1, 2, 3, 4, 5, 6),
    (2, 'clothes', 10, 20, 30, 40, 50, 60),
    (3, 'cars', 100, 200, 300, 400, 500, 600);

FROM monthly_sales;
```

empid	dept	Jan	Feb	Mar	Apr	May	Jun
1	electronics	1	2	3	4	5	6
2	clothes	10	20	30	40	50	60
3	cars	100	200	300	400	500	600

UNPIVOT Manually

The most typical UNPIVOT transformation is to take already pivoted data and re-stack it into a column each for the name and value. In this case, all months will be stacked into a `month` column and a `sales` column.

```
UNPIVOT monthly_sales
ON jan, feb, mar, apr, may, jun
INTO
    NAME month
    VALUE sales;
```

empid	dept	month	sales
1	electronics	Jan	1
1	electronics	Feb	2
1	electronics	Mar	3
1	electronics	Apr	4

empid	dept	month	sales
1	electronics	May	5
1	electronics	Jun	6
2	clothes	Jan	10
2	clothes	Feb	20
2	clothes	Mar	30
2	clothes	Apr	40
2	clothes	May	50
2	clothes	Jun	60
3	cars	Jan	100
3	cars	Feb	200
3	cars	Mar	300
3	cars	Apr	400
3	cars	May	500
3	cars	Jun	600

`UNPIVOT` Dynamically Using `COLUMNS` Expression

In many cases, the number of columns to unpivot is not easy to predetermine ahead of time. In the case of this dataset, the query above would have to change each time a new month is added. The COLUMNS expression can be used to select all columns that are not `empid` or `dept`. This enables dynamic unpivoting that will work regardless of how many months are added. The query below returns identical results to the one above.

```
UNPIVOT monthly_sales
ON COLUMNS(* EXCLUDE (empid, dept))
INTO
    NAME month
    VALUE sales;
```

empid	dept	month	sales
1	electronics	Jan	1
1	electronics	Feb	2
1	electronics	Mar	3
1	electronics	Apr	4
1	electronics	May	5
1	electronics	Jun	6
2	clothes	Jan	10
2	clothes	Feb	20
2	clothes	Mar	30
2	clothes	Apr	40
2	clothes	May	50
2	clothes	Jun	60
3	cars	Jan	100

empid	dept	month	sales
3	cars	Feb	200
3	cars	Mar	300
3	cars	Apr	400
3	cars	May	500
3	cars	Jun	600

`UNPIVOT` into Multiple Value Columns

The `UNPIVOT` statement has additional flexibility: more than 2 destination columns are supported. This can be useful when the goal is to reduce the extent to which a dataset is pivoted, but not completely stack all pivoted columns. To demonstrate this, the query below will generate a dataset with a separate column for the number of each month within the quarter (month 1, 2, or 3), and a separate row for each quarter. Since there are fewer quarters than months, this does make the dataset longer, but not as long as the above.

To accomplish this, multiple sets of columns are included in the `ON` clause. The `q1` and `q2` aliases are optional. The number of columns in each set of columns in the `ON` clause must match the number of columns in the `VALUE` clause.

```
UNPIVOT monthly_sales
    ON (jan, feb, mar) AS q1, (apr, may, jun) AS q2
    INTO
        NAME quarter
        VALUE month_1_sales, month_2_sales, month_3_sales;
```

empid	dept	quarter	month_1_sales	month_2_sales	month_3_sales
1	electronics	q1	1	2	3
1	electronics	q2	4	5	6
2	clothes	q1	10	20	30
2	clothes	q2	40	50	60
3	cars	q1	100	200	300
3	cars	q2	400	500	600

Using `UNPIVOT` within a `SELECT` Statement

The `UNPIVOT` statement may be included within a `SELECT` statement as a CTE (a Common Table Expression, or WITH clause), or a subquery. This allows for an `UNPIVOT` to be used alongside other SQL logic, as well as for multiple `UNPIVOT`s to be used in one query.

No `SELECT` is needed within the CTE, the `UNPIVOT` keyword can be thought of as taking its place.

```
WITH unpivot_alias AS (
    UNPIVOT monthly_sales
    ON COLUMNS(* EXCLUDE (empid, dept))
    INTO
        NAME month
        VALUE sales
)
SELECT * FROM unpivot_alias;
```

An `UNPIVOT` may be used in a subquery and must be wrapped in parentheses. Note that this behavior is different than the SQL Standard Unpivot, as illustrated in subsequent examples.

```
SELECT *
FROM (
    UNPIVOT monthly_sales
    ON COLUMNS(* EXCLUDE (empid, dept))
    INTO
        NAME month
        VALUE sales
) unpivot_alias;
```

Expressions within `UNPIVOT` Statements

DuckDB allows expressions within the `UNPIVOT` statements, provided that they only involve a single column. These can be used to perform computations as well as explicit casts. For example:

```
UNPIVOT
    (SELECT 42 AS col1, 'woot' AS col2)
    ON
        (col1 * 2)::VARCHAR,
        col2;
```

name	value
col1	84
col2	woot

Simplified `UNPIVOT` Full Syntax Diagram

Below is the full syntax diagram of the `UNPIVOT` statement.

SQL Standard `UNPIVOT` Syntax

The full syntax diagram is below, but the SQL Standard `UNPIVOT` syntax can be summarized as:

```
FROM [dataset]
UNPIVOT [INCLUDE NULLS] (
    [value-column-name(s)]
    FOR [name-column-name] IN [column(s)]
);
```

Note that only one column can be included in the `name-column-name` expression.

SQL Standard `UNPIVOT` Manually

To complete the basic `UNPIVOT` operation using the SQL standard syntax, only a few additions are needed.

```
FROM monthly_sales UNPIVOT (
    sales
    FOR month IN (jan, feb, mar, apr, may, jun)
);
```

empid	dept	month	sales
1	electronics	Jan	1

empid	dept	month	sales
1	electronics	Feb	2
1	electronics	Mar	3
1	electronics	Apr	4
1	electronics	May	5
1	electronics	Jun	6
2	clothes	Jan	10
2	clothes	Feb	20
2	clothes	Mar	30
2	clothes	Apr	40
2	clothes	May	50
2	clothes	Jun	60
3	cars	Jan	100
3	cars	Feb	200
3	cars	Mar	300
3	cars	Apr	400
3	cars	May	500
3	cars	Jun	600

SQL Standard `UNPIVOT` Dynamically Using the `COLUMNS` Expression

The `COLUMNS` expression can be used to determine the `IN` list of columns dynamically. This will continue to work even if additional `month` columns are added to the dataset. It produces the same result as the query above.

```
FROM monthly_sales UNPIVOT (
    sales
    FOR month IN (columns(* EXCLUDE (empid, dept)))
);
```

SQL Standard `UNPIVOT` into Multiple Value Columns

The `UNPIVOT` statement has additional flexibility: more than 2 destination columns are supported. This can be useful when the goal is to reduce the extent to which a dataset is pivoted, but not completely stack all pivoted columns. To demonstrate this, the query below will generate a dataset with a separate column for the number of each month within the quarter (month 1, 2, or 3), and a separate row for each quarter. Since there are fewer quarters than months, this does make the dataset longer, but not as long as the above.

To accomplish this, multiple columns are included in the `value-column-name` portion of the `UNPIVOT` statement. Multiple sets of columns are included in the `IN` clause. The `q1` and `q2` aliases are optional. The number of columns in each set of columns in the `IN` clause must match the number of columns in the `value-column-name` portion.

```
FROM monthly_sales
UNPIVOT (
    (month_1_sales, month_2_sales, month_3_sales)
    FOR quarter IN (
        (jan, feb, mar) AS q1,
        (apr, may, jun) AS q2
    )
);
```

empid	dept	quarter	month_1_sales	month_2_sales	month_3_sales
1	electronics	q1	1	2	3
1	electronics	q2	4	5	6
2	clothes	q1	10	20	30
2	clothes	q2	40	50	60
3	cars	q1	100	200	300
3	cars	q2	400	500	600

SQL Standard `UNPIVOT` Full Syntax Diagram

Below is the full syntax diagram of the SQL Standard version of the `UNPIVOT` statement.

UPDATE Statement

The `UPDATE` statement modifies the values of rows in a table.

Examples

For every row where `i` is `NULL`, set the value to 0 instead:

```
UPDATE tbl
SET i = 0
WHERE i IS NULL;
```

Set all values of `i` to 1 and all values of `j` to 2:

```
UPDATE tbl
SET i = 1, j = 2;
```

Syntax

`UPDATE` changes the values of the specified columns in all rows that satisfy the condition. Only the columns to be modified need be mentioned in the `SET` clause; columns not explicitly modified retain their previous values.

Update from Other Table

A table can be updated based upon values from another table. This can be done by specifying a table in a `FROM` clause, or using a sub-select statement. Both approaches have the benefit of completing the `UPDATE` operation in bulk for increased performance.

```
CREATE OR REPLACE TABLE original AS
    SELECT 1 AS key, 'original value' AS value
    UNION ALL
    SELECT 2 AS key, 'original value 2' AS value;

CREATE OR REPLACE TABLE new AS
    SELECT 1 AS key, 'new value' AS value
    UNION ALL
    SELECT 2 AS key, 'new value 2' AS value;

SELECT *
FROM original;
```

key	value
1	original value
2	original value 2

```
UPDATE original
    SET value = new.value
    FROM new
    WHERE original.key = new.key;
```

Or:

```
UPDATE original
    SET value = (
        SELECT
            new.value
        FROM new
        WHERE original.key = new.key
    );

SELECT *
FROM original;
```

key	value
1	new value
2	new value 2

Update from Same Table

The only difference between this case and the above is that a different table alias must be specified on both the target table and the source table. In this example `AS true_original` and `AS new` are both required.

```
UPDATE original AS true_original
    SET value = (
        SELECT
            new.value || ' a change!' AS value
        FROM original AS new
        WHERE true_original.key = new.key
    );
```

Update Using Joins

To select the rows to update, `UPDATE` statements can use the `FROM` clause and express joins via the `WHERE` clause. For example:

```
CREATE TABLE city (name VARCHAR, revenue BIGINT, country_code VARCHAR);
CREATE TABLE country (code VARCHAR, name VARCHAR);
INSERT INTO city VALUES ('Paris', 700, 'FR'), ('Lyon', 200, 'FR'), ('Brussels', 400, 'BE');
INSERT INTO country VALUES ('FR', 'France'), ('BE', 'Belgium');
```

To increase the revenue of all cities in France, join the `city` and the `country` tables, and filter on the latter:

```
UPDATE city
SET revenue = revenue + 100
FROM country
WHERE city.country_code = country.code
  AND country.name = 'France';
```

```
SELECT *
FROM city;
```

name	revenue	country_code
Paris	800	FR
Lyon	300	FR
Brussels	400	BE

Upsert (Insert or Update)

See the Insert documentation for details.

USE Statement

The USE statement selects a database and optional schema, or just a schema to use as the default.

Examples

```
--- Sets the 'memory' database as the default. Will use 'main' schema implicitly or error
--- if it does not exist.
USE memory;
--- Sets the 'duck.main' database and schema as the default
USE duck.main;
-- Sets the `main` schema of the currently selected database as the default, in this case 'duck.main'
USE main;
```

Syntax

The USE statement sets a default database, schema or database/schema combination to use for future operations. For instance, tables created without providing a fully qualified table name will be created in the default database.

VACUUM Statement

The VACUUM statement only has basic support in DuckDB and is mostly provided for PostgreSQL-compatibility.

Some variants of it, such as when calling for a given column, recompute the distinct statistics (the number of distinct entities) if they have become stale due to updates.

> **Warning.** The behavior of VACUUM is not consistent with PostgreSQL semantics and it is likely going to change in the future.

Examples

No-op:

```
VACUUM;
```

No-op:

```
VACUUM ANALYZE;
```

Calling VACUUM on a given table-column pair rebuilds statistics for the table and column:

```
VACUUM my_table(my_column);
```

Rebuild statistics for the table and column:

```
VACUUM ANALYZE my_table(my_column);
```

The following operation is not supported:

```
VACUUM FULL;
```

```
Not implemented Error:
Full vacuum option
```

Vacuum with Indexes

> **Warning.** This feature is experimental.

By default, VACUUM skips tables that have ART indexes. The `vacuum_rebuild_indexes` setting enables vacuum to compact row groups on tables with indexes by rebuilding the indexes afterward. The setting specifies a row count threshold: tables exceeding the threshold are skipped. Set to `0` to disable (the default).

```
SET vacuum_rebuild_indexes = 1000000;
```

Reclaiming Space

The VACUUM statement does not reclaim space. For instructions on reclaiming space, refer to the "Reclaiming space" page.

Syntax

Query Syntax

SELECT Clause

The SELECT clause specifies the list of columns that will be returned by the query. While it appears first in the clause, *logically* the expressions here are executed only at the end. The SELECT clause can contain arbitrary expressions that transform the output, as well as aggregates and window functions.

Examples

Select all columns from the table called `tbl`:

```
SELECT * FROM tbl;
```

Perform arithmetic on the columns in a table, and provide an alias:

```
SELECT col1 + col2 AS res, sqrt(col1) AS root FROM tbl;
```

Use prefix aliases:

```
SELECT
    res: col1 + col2,
    root: sqrt(col1)
FROM tbl;
```

Select all unique cities from the `addresses` table:

```
SELECT DISTINCT city FROM addresses;
```

Return the total number of rows in the `addresses` table:

```
SELECT count(*) FROM addresses;
```

Select all columns except the city column from the `addresses` table:

```
SELECT * EXCLUDE (city) FROM addresses;
```

Select all columns from the `addresses` table, but replace `city` with `lower(city)`:

```
SELECT * REPLACE (lower(city) AS city) FROM addresses;
```

Select all columns matching the given regular expression from the table:

```
SELECT COLUMNS('number\d+') FROM addresses;
```

Compute a function on all given columns of a table:

```
SELECT min(COLUMNS(*)) FROM addresses;
```

To select columns with spaces or special characters, use double quotes (`"`):

```
SELECT "Some Column Name" FROM tbl;
```

Syntax

SELECT List

The SELECT clause contains a list of expressions that specify the result of a query. The select list can refer to any columns in the FROM clause, and combine them using expressions. As the output of a SQL query is a table – every expression in the SELECT clause also has a name. The expressions can be explicitly named using the AS clause (e.g., `expr AS name`). If a name is not provided by the user the expressions are named automatically by the system.

> Column names are case-insensitive. See the Rules for Case Sensitivity for more details.

Star Expressions

Select all columns from the table called `tbl`:

```
SELECT *
FROM tbl;
```

Select all columns matching the given regular expression from the table:

```
SELECT COLUMNS('number\d+')
FROM addresses;
```

The star expression is a special expression that expands to *multiple expressions* based on the contents of the FROM clause. In the simplest case, * expands to **all** expressions in the FROM clause. Columns can also be selected using regular expressions or lambda functions. See the star expression page for more details.

DISTINCT Clause

Select all unique cities from the addresses table:

```
SELECT DISTINCT city
FROM addresses;
```

The DISTINCT clause can be used to return **only** the unique rows in the result – so that any duplicate rows are filtered out.

> Queries starting with `SELECT DISTINCT` run deduplication, which is an expensive operation. Therefore, only use DISTINCT if necessary.

DISTINCT ON Clause

Select only the highest population city for each country:

```
SELECT DISTINCT ON(country) city, population
FROM cities
ORDER BY population DESC;
```

The `DISTINCT ON` clause returns only one row per unique value in the set of expressions as defined in the ON clause. If an `ORDER BY` clause is present, the row that is returned is the first row that is encountered as per the `ORDER BY` criteria. If an `ORDER BY` clause is not present, the first row that is encountered is not defined and can be any row in the table.

> When querying large datasets, using DISTINCT on all columns can be expensive. Therefore, consider using `DISTINCT ON` on a column (or a set of columns) which guarantees a sufficient degree of uniqueness for your results. For example, using `DISTINCT ON` on the key column(s) of a table guarantees full uniqueness.

Aggregates

Return the total number of rows in the addresses table:

```
SELECT count(*)
FROM addresses;
```

Return the total number of rows in the addresses table grouped by city:

```
SELECT city, count(*)
FROM addresses
GROUP BY city;
```

Aggregate functions are special functions that *combine* multiple rows into a single value. When aggregate functions are present in the `SELECT` clause, the query is turned into an aggregate query. In an aggregate query, **all** expressions must either be part of an aggregate function, or part of a group (as specified by the `GROUP BY clause`).

Window Functions

Generate a `row_number` column containing incremental identifiers for each row:

```
SELECT row_number() OVER ()
FROM sales;
```

Compute the difference between the current amount, and the previous amount, by order of time:

```
SELECT amount - lag(amount) OVER (ORDER BY time)
FROM sales;
```

Window functions are special functions that allow the computation of values relative to *other rows* in a result. Window functions are marked by the `OVER` clause which contains the *window specification*. The window specification defines the frame or context in which the window function is computed. See the window functions page for more information.

`unnest` Function

Unnest an array by one level:

```
SELECT unnest([1, 2, 3]);
```

Unnest a struct by one level:

```
SELECT unnest({'a': 42, 'b': 84});
```

The `unnest` function is a special function that can be used together with arrays, lists, or structs. The unnest function strips one level of nesting from the type. For example, `INTEGER[]` is transformed into `INTEGER`. `STRUCT(a INTEGER, b INTEGER)` is transformed into `a INTEGER, b INTEGER`. The unnest function can be used to transform nested types into regular scalar types, which makes them easier to operate on.

FROM and JOIN Clauses

The `FROM` clause specifies the *source* of the data on which the remainder of the query should operate. Logically, the `FROM` clause is where the query starts execution. The `FROM` clause can contain a single table, a combination of multiple tables that are joined together using `JOIN` clauses, or another `SELECT` query inside a subquery node. DuckDB also has an optional `FROM`-first syntax which enables you to also query without a `SELECT` statement.

Examples

Select all columns from the table called `tbl`:

```
SELECT *
FROM tbl;
```

Select all columns from the table using the FROM-first syntax:

```
FROM tbl
SELECT *;
```

Select all columns using the FROM-first syntax and omitting the `SELECT` clause:

```
FROM tbl;
```

Select all columns from the table called `tbl` through an alias `tn`:

```
SELECT tn.*
FROM tbl tn;
```

Use a prefix alias:

```
SELECT tn.*
FROM tn: tbl;
```

Select all columns from the table `tbl` in the schema `schema_name`:

```
SELECT *
FROM schema_name.tbl;
```

Select the column `i` from the table function `range`, where the first column of the range function is renamed to `i`:

```
SELECT t.i
FROM range(100) AS t(i);
```

Select all columns from the CSV file called `test.csv`:

```
SELECT *
FROM 'test.csv';
```

Select all columns from a subquery:

```
SELECT *
FROM (SELECT * FROM tbl);
```

Select the entire row of the table as a struct:

```
SELECT t
FROM t;
```

Select the entire row of the subquery as a struct (i.e., a single column):

```
SELECT t
FROM (SELECT unnest(generate_series(41, 43)) AS x, 'hello' AS y) t;
```

Join two tables together:

```
SELECT *
FROM tbl
JOIN other_table
  ON tbl.key = other_table.key;
```

Select a 10% sample from a table:

```
SELECT *
FROM tbl
TABLESAMPLE 10%;
```

Select a sample of 10 rows from a table:

```
SELECT *
FROM tbl
TABLESAMPLE 10 ROWS;
```

Use the FROM-first syntax with WHERE clause and aggregation:

```
FROM range(100) AS t(i)
SELECT sum(t.i)
WHERE i % 2 = 0;
```

Table Functions

Some functions in DuckDB return entire tables rather than individual values. These functions are accordingly called *table functions* and can be used with a FROM clause like regular table references. Examples include `read_csv`, `read_parquet`, `range`, `generate_series`, `repeat`, `unnest`, and `glob` (note that some of the examples here can be used as both scalar and table functions).

For example,

```
SELECT *
FROM 'test.csv';
```

is implicitly translated to a call of the `read_csv` table function:

```
SELECT *
FROM read_csv('test.csv');
```

All table functions support a `WITH ORDINALITY` suffix, which extends the returned table by an integer column `ordinality` that enumerates the generated rows starting at 1.

```
SELECT *
FROM read_csv('test.csv') WITH ORDINALITY;
```

Note that the same result could be achieved using the `row_number` window function. In the presence of joins, however, `WITH ORDINALITY` allows enumerating one side of the join instead of the final result set, without having to resort to sub-queries.

Joins

Joins are a fundamental relational operation used to connect two tables or relations horizontally. The relations are referred to as the *left* and *right* sides of the join based on how they are written in the join clause. Each result row has the columns from both relations.

A join uses a rule to match pairs of rows from each relation. Often this is a predicate, but there are other implied rules that may be specified.

Outer Joins

Rows that do not have any matches can still be returned if an OUTER join is specified. Outer joins can be one of:

- LEFT (All rows from the left relation appear at least once)
- RIGHT (All rows from the right relation appear at least once)
- FULL (All rows from both relations appear at least once)

A join that is not OUTER is INNER (only rows that get paired are returned).

When an unpaired row is returned, the attributes from the other table are set to NULL.

Cross Product Joins (Cartesian Product)

The simplest type of join is a `CROSS JOIN`. There are no conditions for this type of join, and it just returns all the possible pairs.

Return all pairs of rows:

```
SELECT a.*, b.*
FROM a
CROSS JOIN b;
```

This is equivalent to omitting the `JOIN` clause:

```
SELECT a.*, b.*
FROM a, b;
```

Conditional Joins

Most joins are specified by a predicate that connects attributes from one side to attributes from the other side. The conditions can be explicitly specified using an `ON` clause with the join (clearer) or implied by the `WHERE` clause (old-fashioned).

We use the `l_regions` and the `l_nations` tables from the TPC-H schema:

```
CREATE TABLE l_regions (
    r_regionkey INTEGER NOT NULL PRIMARY KEY,
    r_name      CHAR(25) NOT NULL,
    r_comment   VARCHAR(152)
);

CREATE TABLE l_nations (
    n_nationkey INTEGER NOT NULL PRIMARY KEY,
    n_name      CHAR(25) NOT NULL,
    n_regionkey INTEGER NOT NULL,
    n_comment   VARCHAR(152),
    FOREIGN KEY (n_regionkey) REFERENCES l_regions(r_regionkey)
);
```

Return the regions for the nations:

```
SELECT n.*, r.*
FROM l_nations n
JOIN l_regions r ON (n_regionkey = r_regionkey);
```

If the column names are the same and are required to be equal, then the simpler `USING` syntax can be used:

```
CREATE TABLE l_regions (regionkey INTEGER NOT NULL PRIMARY KEY,
                        name      CHAR(25) NOT NULL,
                        comment   VARCHAR(152));

CREATE TABLE l_nations (nationkey INTEGER NOT NULL PRIMARY KEY,
                        name      CHAR(25) NOT NULL,
                        regionkey INTEGER NOT NULL,
                        comment   VARCHAR(152),
                        FOREIGN KEY (regionkey) REFERENCES l_regions(regionkey));
```

Return the regions for the nations:

```
SELECT n.*, r.*
FROM l_nations n
JOIN l_regions r USING (regionkey);
```

The expressions do not have to be equalities – any predicate can be used:

Return the pairs of jobs where one ran longer but cost less:

```
SELECT s1.t_id, s2.t_id
FROM west s1, west s2
WHERE s1.time > s2.time
  AND s1.cost < s2.cost;
```

Natural Joins

Natural joins join two tables based on attributes that share the same name.

For example, take the following example with cities, airport codes and airport names. Note that both tables are intentionally incomplete, i.e., they do not have a matching pair in the other table.

```
CREATE TABLE city_airport (city_name VARCHAR, iata VARCHAR);
CREATE TABLE airport_names (iata VARCHAR, airport_name VARCHAR);
INSERT INTO city_airport VALUES
    ('Amsterdam', 'AMS'),
    ('Rotterdam', 'RTM'),
    ('Eindhoven', 'EIN'),
    ('Groningen', 'GRQ');
INSERT INTO airport_names VALUES
    ('AMS', 'Amsterdam Airport Schiphol'),
    ('RTM', 'Rotterdam The Hague Airport'),
    ('MST', 'Maastricht Aachen Airport');
```

To join the tables on their shared `IATA` attributes, run:

```
SELECT *
FROM city_airport
NATURAL JOIN airport_names;
```

This produces the following result:

city_name	iata	airport_name
Amsterdam	AMS	Amsterdam Airport Schiphol
Rotterdam	RTM	Rotterdam The Hague Airport

Note that only rows where the same `iata` attribute was present in both tables were included in the result.

We can also express this query using the vanilla `JOIN` clause with the `USING` keyword:

```
SELECT *
FROM city_airport
JOIN airport_names
USING (iata);
```

Semi and Anti Joins

Semi joins return rows from the left table that have at least one match in the right table. Anti joins return rows from the left table that have *no* matches in the right table. When using a semi or anti join the result will never have more rows than the left hand side table. Semi joins provide the same logic as the `IN` operator statement. Anti joins provide the same logic as the `NOT IN` operator, except anti joins ignore `NULL` values from the right table.

Semi Join Example Return a list of city–airport code pairs from the `city_airport` table where the airport name **is available** in the `airport_names` table:

```
SELECT *
FROM city_airport
SEMI JOIN airport_names
    USING (iata);
```

city_name	iata
Amsterdam	AMS
Rotterdam	RTM

This query is equivalent to:

```
SELECT *
FROM city_airport
WHERE iata IN (SELECT iata FROM airport_names);
```

Anti Join Example Return a list of city–airport code pairs from the `city_airport` table where the airport name **is not available** in the `airport_names` table:

```
SELECT *
FROM city_airport
ANTI JOIN airport_names
    USING (iata);
```

city_name	iata
Eindhoven	EIN
Groningen	GRQ

This query is equivalent to:

```
SELECT *
FROM city_airport
WHERE iata NOT IN (SELECT iata FROM airport_names WHERE iata IS NOT NULL);
```

Lateral Joins

The LATERAL keyword allows subqueries in the FROM clause to refer to previous subqueries. This feature is also known as a *lateral join*.

```
SELECT *
FROM range(3) t(i), LATERAL (SELECT i + 1) t2(j);
```

i	j
0	1
2	3
1	2

Lateral joins are a generalization of correlated subqueries, as they can return multiple values per input value rather than only a single value.

```
SELECT *
FROM
    generate_series(0, 1) t(i),
    LATERAL (SELECT i + 10 UNION ALL SELECT i + 100) t2(j);
```

i	j
0	10
1	11
0	100
1	101

It may be helpful to think about LATERAL as a loop where we iterate through the rows of the first subquery and use it as input to the second (LATERAL) subquery. In the examples above, we iterate through table `t` and refer to its column `i` from the definition of table `t2`. The rows of `t2` form column `j` in the result.

It is possible to refer to multiple attributes from the LATERAL subquery. Using the table from the first example:

```
CREATE TABLE t1 AS
    SELECT *
    FROM range(3) t(i), LATERAL (SELECT i + 1) t2(j);

SELECT *
    FROM t1, LATERAL (SELECT i + j) t2(k)
    ORDER BY ALL;
```

i	j	k
0	1	1
1	2	3
2	3	5

> DuckDB detects when LATERAL joins should be used, making the use of the LATERAL keyword optional.

Positional Joins

When working with data frames or other embedded tables of the same size, the rows may have a natural correspondence based on their physical order. In scripting languages, this is easily expressed using a loop:

```
for (i = 0; i < n; i++) {
    f(t1.a[i], t2.b[i]);
}
```

It is difficult to express this in standard SQL because relational tables are not ordered, but imported tables such as data frames or disk files (like CSVs or Parquet files) do have a natural ordering.

Connecting them using this ordering is called a *positional join:*

```
CREATE TABLE t1 (x INTEGER);
CREATE TABLE t2 (s VARCHAR);

INSERT INTO t1 VALUES (1), (2), (3);
INSERT INTO t2 VALUES ('a'), ('b');
```

```
SELECT *
FROM t1
POSITIONAL JOIN t2;
```

x	s
1	a
2	b
3	NULL

Positional joins are always `FULL OUTER` joins, i.e., the resulting table has the length of the longer input table and the missing entries are filled with `NULL` values.

As-Of Joins

A common operation when working with temporal or similarly-ordered data is to find the nearest (first) event in a reference table (such as prices). This is called an *as-of join:*

Attach prices to stock trades:

```
SELECT t.*, p.price
FROM trades t
ASOF JOIN prices p
       ON t.symbol = p.symbol AND t.when >= p.when;
```

The `ASOF` join requires at least one inequality condition on the ordering field. The inequality can be any inequality condition (`>=`, `>`, `<=`, `<`) on any data type, but the most common form is `>=` on a temporal type. Any other conditions must be equalities (or `NOT DISTINCT`). This means that the left/right order of the tables is significant.

`ASOF` joins each left side row with at most one right side row. It can be specified as an `OUTER` join to find unpaired rows (e.g., trades without prices or prices which have no trades.)

Attach prices or NULLs to stock trades:

```
SELECT *
FROM trades t
ASOF LEFT JOIN prices p
            ON t.symbol = p.symbol
           AND t.when >= p.when;
```

`ASOF` joins can also specify join conditions on matching column names with the `USING` syntax, but the *last* attribute in the list must be the inequality, which will be greater than or equal to (`>=`):

```
SELECT *
FROM trades t
ASOF JOIN prices p USING (symbol, "when");
```

Returns symbol, trades.when, price (but NOT prices.when):

If you combine `USING` with a `SELECT *` like this, the query will return the left side (probe) column values for the matches, not the right side (build) column values. To get the `prices` times in the example, you will need to list the columns explicitly:

```
SELECT t.symbol, t.when AS trade_when, p.when AS price_when, price
FROM trades t
ASOF LEFT JOIN prices p USING (symbol, "when");
```

Self-Joins

DuckDB allows self-joins for all types of joins. Note that tables need to be aliased, using the same table name without aliases will result in an error:

```
CREATE TABLE t (x INTEGER);
SELECT * FROM t JOIN t USING(x);
```

```
Binder Error:
Duplicate alias "t" in query!
```

Adding the aliases allows the query to parse successfully:

```
SELECT * FROM t AS t1 JOIN t AS t2 USING(x);
```

Shorthands in the `JOIN` Clause

You can specify column names in the `JOIN` clause:

```
CREATE TABLE t1 (x INTEGER);
CREATE TABLE t2 (y INTEGER);
INSERT INTO t1 VALUES (1), (2), (4);
INSERT INTO t2 VALUES (2), (3);
SELECT * FROM t1 NATURAL JOIN t2 t2(x);
```

x
2

You can also use the `VALUES` clause in the `JOIN` clause:

```
SELECT * FROM t1 NATURAL JOIN (VALUES (2), (4)) _(x);
```

x
2
4

FROM-First Syntax

DuckDB's SQL supports the FROM-first syntax, i.e., it allows putting the `FROM` clause before the `SELECT` clause or completely omitting the `SELECT` clause. We use the following example to demonstrate it:

```
CREATE TABLE tbl AS
    SELECT *
    FROM (VALUES ('a'), ('b')) t1(s), range(1, 3) t2(i);
```

FROM-First Syntax with a `SELECT` Clause

The following statement demonstrates the use of the FROM-first syntax:

```
FROM tbl
SELECT i, s;
```

This is equivalent to:

```
SELECT i, s
FROM tbl;
```

i	s
1	a
2	a
1	b
2	b

FROM-First Syntax without a SELECT Clause

The following statement demonstrates the use of the optional `SELECT` clause:

```
FROM tbl;
```

This is equivalent to:

```
SELECT *
FROM tbl;
```

s	i
a	1
a	2
b	1
b	2

Syntax

WHERE Clause

The `WHERE` clause specifies any filters to apply to the data. This allows you to select only a subset of the data in which you are interested. Logically the `WHERE` clause is applied immediately after the `FROM` clause.

Examples

Select all rows where the `id` is equal to 3:

```
SELECT *
FROM tbl
WHERE id = 3;
```

Select all rows that match the given **case-sensitive** `LIKE` expression:

```
SELECT *
FROM tbl
WHERE name LIKE '%mark%';
```

Select all rows that match the given **case-insensitive** expression formulated with the `ILIKE` operator:

```sql
SELECT *
FROM tbl
WHERE name ILIKE '%mark%';
```

Select all rows that match the given composite expression:

```sql
SELECT *
FROM tbl
WHERE id = 3 OR id = 7;
```

Syntax

GROUP BY Clause

The GROUP BY clause specifies which grouping columns should be used to perform any aggregations in the SELECT clause. If the GROUP BY clause is specified, the query is always an aggregate query, even if no aggregations are present in the SELECT clause.

When a GROUP BY clause is specified, all tuples that have matching data in the grouping columns (i.e., all tuples that belong to the same group) will be combined. The values of the grouping columns themselves are unchanged, and any other columns can be combined using an aggregate function (such as `count`, `sum`, `avg`, etc).

GROUP BY ALL

Use GROUP BY ALL to GROUP BY all columns in the SELECT statement that are not wrapped in aggregate functions. This simplifies the syntax by allowing the columns list to be maintained in a single location, and prevents bugs by keeping the SELECT granularity aligned to the GROUP BY granularity (e.g., it prevents duplication). See examples below and additional examples in the "Friendlier SQL with DuckDB" blog post.

Multiple Dimensions

Normally, the GROUP BY clause groups along a single dimension. Using the GROUPING SETS, CUBE or ROLLUP clauses it is possible to group along multiple dimensions. See the GROUPING SETS page for more information.

Examples

Count the number of entries in the `addresses` table that belong to each different city:

```sql
SELECT city, count(*)
FROM addresses
GROUP BY city;
```

Compute the average income per city per street_name:

```sql
SELECT city, street_name, avg(income)
FROM addresses
GROUP BY city, street_name;
```

GROUP BY ALL Examples

Group by city and street_name to remove any duplicate values:

```sql
SELECT city, street_name
FROM addresses
GROUP BY ALL;
```

Compute the average income per city per street_name. Since income is wrapped in an aggregate function, do not include it in the GROUP BY:

```
SELECT city, street_name, avg(income)
FROM addresses
GROUP BY ALL;
-- GROUP BY city, street_name:
```

Syntax

GROUPING SETS

GROUPING SETS, ROLLUP and CUBE can be used in the GROUP BY clause to perform a grouping over multiple dimensions within the same query. Note that this syntax is not compatible with `GROUP BY ALL`.

Examples

Compute the average income along the provided four different dimensions:

```
-- the syntax () denotes the empty set (i.e., computing an ungrouped aggregate)
SELECT city, street_name, avg(income)
FROM addresses
GROUP BY GROUPING SETS ((city, street_name), (city), (street_name), ());
```

Compute the average income along the same dimensions:

```
SELECT city, street_name, avg(income)
FROM addresses
GROUP BY CUBE (city, street_name);
```

Compute the average income along the dimensions `(city, street_name)`, `(city)` and `()`:

```
SELECT city, street_name, avg(income)
FROM addresses
GROUP BY ROLLUP (city, street_name);
```

Description

GROUPING SETS performs the same aggregate across different GROUP BY clauses in a single query.

```
CREATE TABLE students (course VARCHAR, type VARCHAR);
INSERT INTO students (course, type)
VALUES
    ('CS', 'Bachelor'), ('CS', 'Bachelor'), ('CS', 'PhD'), ('Math', 'Masters'),
    ('CS', NULL), ('CS', NULL), ('Math', NULL);

SELECT course, type, count(*)
FROM students
GROUP BY GROUPING SETS ((course, type), course, type, ());
```

course	type	count_star()
Math	NULL	1
NULL	NULL	7
CS	PhD	1

course	type	count_star()
CS	Bachelor	2
Math	Masters	1
CS	NULL	2
Math	NULL	2
CS	NULL	5
NULL	NULL	3
NULL	Masters	1
NULL	Bachelor	2
NULL	PhD	1

In the above query, we group across four different sets: `course, type`, `course`, `type` and `()` (the empty group). The result contains `NULL` for a group which is not in the grouping set for the result, i.e., the above query is equivalent to the following statement of `UNION ALL` clauses:

```
-- Group by course, type:
SELECT course, type, count(*)
FROM students
GROUP BY course, type
UNION ALL
-- Group by type:
SELECT NULL AS course, type, count(*)
FROM students
GROUP BY type
UNION ALL
-- Group by course:
SELECT course, NULL AS type, count(*)
FROM students
GROUP BY course
UNION ALL
-- Group by nothing:
SELECT NULL AS course, NULL AS type, count(*)
FROM students;
```

`CUBE` and `ROLLUP` are syntactic sugar to easily produce commonly used grouping sets.

The `ROLLUP` clause will produce all "sub-groups" of a grouping set, e.g., `ROLLUP (country, city, zip)` produces the grouping sets `(country, city, zip)`, `(country, city)`, `(country)`, `()`. This can be useful for producing different levels of detail of a group by clause. This produces `n+1` grouping sets where n is the amount of terms in the `ROLLUP` clause.

`CUBE` produces grouping sets for all combinations of the inputs, e.g., `CUBE (country, city, zip)` will produce `(country, city, zip)`, `(country, city)`, `(country, zip)`, `(city, zip)`, `(country)`, `(city)`, `(zip)`, `()`. This produces `2^n` grouping sets.

Identifying Grouping Sets with `GROUPING_ID()`

The super-aggregate rows generated by `GROUPING SETS`, `ROLLUP` and `CUBE` can often be identified by `NULL`-values returned for the respective column in the grouping. But if the columns used in the grouping can themselves contain actual `NULL`-values, then it can be challenging to distinguish whether the value in the resultset is a "real" `NULL`-value coming out of the data itself, or a `NULL`-value generated by the grouping construct. The `GROUPING_ID()` or `GROUPING()` function is designed to identify which groups generated the super-aggregate rows in the result.

`GROUPING_ID()` is an aggregate function that takes the column expressions that make up the grouping(s). It returns a `BIGINT` value. The return value is `0` for the rows that are not super-aggregate rows. But for the super-aggregate rows, it returns an integer value that identifies the combination of expressions that make up the group for which the super-aggregate is generated. At this point, an example might help. Consider the following query:

```
WITH days AS (
    SELECT
        year("generate_series")    AS y,
        quarter("generate_series") AS q,
        month("generate_series")   AS m
    FROM generate_series(DATE '2023-01-01', DATE '2023-12-31', INTERVAL 1 DAY)
)
SELECT y, q, m, GROUPING_ID(y, q, m) AS "grouping_id()"
FROM days
GROUP BY GROUPING SETS (
    (y, q, m),
    (y, q),
    (y),
    ()
)
ORDER BY y, q, m;
```

These are the results:

y	q	m	grouping_id()
2023	1	1	0
2023	1	2	0
2023	1	3	0
2023	1	NULL	1
2023	2	4	0
2023	2	5	0
2023	2	6	0
2023	2	NULL	1
2023	3	7	0
2023	3	8	0
2023	3	9	0
2023	3	NULL	1
2023	4	10	0
2023	4	11	0
2023	4	12	0
2023	4	NULL	1
2023	NULL	NULL	3
NULL	NULL	NULL	7

In this example, the lowest level of grouping is at the month level, defined by the grouping set `(y, q, m)`. Result rows corresponding to that level are simply aggregate rows and the `GROUPING_ID(y, q, m)` function returns `0` for those. The grouping set `(y, q)` results in super-aggregate rows over the month level, leaving a `NULL`-value for the `m` column, and for which `GROUPING_ID(y, q, m)` returns `1`. The grouping set `(y)` results in super-aggregate rows over the quarter level, leaving `NULL`-values for the `m` and `q` column, for which `GROUPING_ID(y, q, m)` returns `3`. Finally, the `()` grouping set results in one super-aggregate row for the entire resultset, leaving `NULL`-values for `y`, `q` and `m` and for which `GROUPING_ID(y, q, m)` returns `7`.

To understand the relationship between the return value and the grouping set, you can think of `GROUPING_ID(y, q, m)` writing to a bitfield, where the first bit corresponds to the last expression passed to `GROUPING_ID()`, the second bit to the one-but-last expression passed to `GROUPING_ID()`, and so on. This may become clearer by casting `GROUPING_ID()` to `BIT`:

```
WITH days AS (
    SELECT
        year("generate_series")    AS y,
        quarter("generate_series") AS q,
        month("generate_series")   AS m
    FROM generate_series(DATE '2023-01-01', DATE '2023-12-31', INTERVAL 1 DAY)
)
SELECT
    y, q, m,
    GROUPING_ID(y, q, m) AS "grouping_id(y, q, m)",
    right(GROUPING_ID(y, q, m)::BIT::VARCHAR, 3) AS "y_q_m_bits"
FROM days
GROUP BY GROUPING SETS (
    (y, q, m),
    (y, q),
    (y),
    ()
)
ORDER BY y, q, m;
```

Which returns these results:

y	q	m	grouping_id(y, q, m)	y_q_m_bits
2023	1	1	0	000
2023	1	2	0	000
2023	1	3	0	000
2023	1	NULL	1	001
2023	2	4	0	000
2023	2	5	0	000
2023	2	6	0	000
2023	2	NULL	1	001
2023	3	7	0	000
2023	3	8	0	000
2023	3	9	0	000
2023	3	NULL	1	001
2023	4	10	0	000
2023	4	11	0	000
2023	4	12	0	000
2023	4	NULL	1	001
2023	NULL	NULL	3	011
NULL	NULL	NULL	7	111

Note that the number of expressions passed to `GROUPING_ID()`, or the order in which they are passed is independent from the actual group definitions appearing in the `GROUPING SETS`-clause (or the groups implied by `ROLLUP` and `CUBE`). As long as the expressions passed to `GROUPING_ID()` are expressions that appear somewhere in the `GROUPING SETS`-clause, `GROUPING_ID()` will set a bit corresponding to the position of the expression whenever that expression is rolled up to a super-aggregate.

Syntax

HAVING Clause

The HAVING clause can be used after the GROUP BY clause to provide filter criteria *after* the grouping has been completed. In terms of syntax the HAVING clause is identical to the WHERE clause, but while the WHERE clause occurs before the grouping, the HAVING clause occurs after the grouping.

Examples

Count the number of entries in the addresses table that belong to each different city, filtering out cities with a count below 50:

```
SELECT city, count(*)
FROM addresses
GROUP BY city
HAVING count(*) >= 50;
```

Compute the average income per city per street_name, filtering out cities with an average income bigger than twice the median income:

```
SELECT city, street_name, avg(income)
FROM addresses
GROUP BY city, street_name
HAVING avg(income) > 2 * median(income);
```

Syntax

ORDER BY Clause

ORDER BY is an output modifier. Logically it is applied near the very end of the query (just prior to LIMIT or OFFSET, if present). The ORDER BY clause sorts the rows on the sorting criteria in either ascending or descending order. In addition, every order clause can specify whether NULL values should be moved to the beginning or to the end.

The ORDER BY clause may contain one or more expressions, separated by commas. An error will be thrown if no expressions are included, since the ORDER BY clause should be removed in that situation. The expressions may begin with either an arbitrary scalar expression (which could be a column name), a column position number (where the indexing starts from 1), or the keyword ALL. Each expression can optionally be followed by an order modifier (ASC or DESC, default is ASC), and/or a NULL order modifier (NULLS FIRST or NULLS LAST, default is NULLS LAST).

ORDER BY ALL

The ALL keyword indicates that the output should be sorted by every column in order from left to right. The direction of this sort may be modified using either ORDER BY ALL ASC or ORDER BY ALL DESC and/or NULLS FIRST or NULLS LAST. Note that ALL may not be used in combination with other expressions in the ORDER BY clause – it must be by itself. See examples below.

NULL Order Modifier

By default, DuckDB sorts ASC and NULLS LAST, i.e., the values are sorted in ascending order and NULL values are placed last. For the default ASC direction this matches PostgreSQL. Note, however, that DuckDB keeps NULLS LAST even for DESC ordering, whereas PostgreSQL places NULLs first on DESC (it treats NULL as the largest value). To match PostgreSQL in both directions, set default_null_order = 'NULLS_LAST_ON_ASC_FIRST_ON_DESC'. The default sort order can be changed with the following configuration options.

Use the `default_null_order` option to change the default `NULL` sorting order to either `NULLS_FIRST`, `NULLS_LAST`, `NULLS_FIRST_ON_ASC_LAST_ON_DESC` or `NULLS_LAST_ON_ASC_FIRST_ON_DESC`:

```
SET default_null_order = 'NULLS_FIRST';
```

Use the `default_order` option to change the direction of the default sorting order to either `DESC` or `ASC`:

```
SET default_order = 'DESC';
```

Collations

Text is sorted using the binary comparison collation by default, which means values are sorted on their binary UTF-8 values. While this works well for ASCII text (e.g., for English language data), the sorting order can be incorrect for other languages. For this purpose, DuckDB provides collations. For more information on collations, see the Collation page.

Examples

All examples use this example table:

```
CREATE OR REPLACE TABLE addresses AS
    SELECT '123 Quack Blvd' AS address, 'DuckTown' AS city, '11111' AS zip
    UNION ALL
    SELECT '111 Duck Duck Goose Ln', 'DuckTown', '11111'
    UNION ALL
    SELECT '111 Duck Duck Goose Ln', 'Duck Town', '11111'
    UNION ALL
    SELECT '111 Duck Duck Goose Ln', 'Duck Town', '11111-0001';
```

Select the addresses, ordered by city name using the default `NULL` order and default order:

```
SELECT *
FROM addresses
ORDER BY city;
```

Select the addresses, ordered by city name in descending order with nulls at the end:

```
SELECT *
FROM addresses
ORDER BY city DESC NULLS LAST;
```

Order by city and then by zip code, both using the default orderings:

```
SELECT *
FROM addresses
ORDER BY city, zip;
```

Order by city using German collation rules:

```
SELECT *
FROM addresses
ORDER BY city COLLATE DE;
```

`ORDER BY ALL` Examples

Order from left to right (by address, then by city, then by zip) in ascending order:

```
SELECT *
FROM addresses
ORDER BY ALL;
```

address	city	zip
111 Duck Duck Goose Ln	Duck Town	11111
111 Duck Duck Goose Ln	Duck Town	11111-0001
111 Duck Duck Goose Ln	DuckTown	11111
123 Quack Blvd	DuckTown	11111

Order from left to right (by address, then by city, then by zip) in descending order:

```
SELECT *
FROM addresses
ORDER BY ALL DESC;
```

address	city	zip
123 Quack Blvd	DuckTown	11111
111 Duck Duck Goose Ln	DuckTown	11111
111 Duck Duck Goose Ln	Duck Town	11111-0001
111 Duck Duck Goose Ln	Duck Town	11111

Syntax

LIMIT and OFFSET Clauses

`LIMIT` is an output modifier. Logically it is applied at the very end of the query. The `LIMIT` clause restricts the amount of rows fetched. The `OFFSET` clause indicates at which position to start reading the values, i.e., the first `OFFSET` values are ignored.

Note that while `LIMIT` can be used without an `ORDER BY` clause, the results might not be deterministic without the `ORDER BY` clause. This can still be useful, however, for example when you want to inspect a quick snapshot of the data.

Examples

Select the first 5 rows from the addresses table:

```
SELECT *
FROM addresses
LIMIT 5;
```

Select the 5 rows from the addresses table, starting at position 5 (i.e., ignoring the first 5 rows):

```
SELECT *
FROM addresses
LIMIT 5
OFFSET 5;
```

Select the top 5 cities with the highest population:

```
SELECT city, count(*) AS population
FROM addresses
GROUP BY city
ORDER BY population DESC
LIMIT 5;
```

Select 10% of the rows from the addresses table:

```
SELECT *
FROM addresses
LIMIT 10%;
```

Syntax

SAMPLE Clause

The SAMPLE clause allows you to run the query on a sample from the base table. This can significantly speed up processing of queries, at the expense of accuracy in the result. Samples can also be used to quickly see a snapshot of the data when exploring a dataset. The sample clause is applied right after anything in the FROM clause (i.e., after any joins, but before the WHERE clause or any aggregates). See the SAMPLE page for more information.

Examples

Select a sample of 1% of the addresses table using default (system) sampling:

```
SELECT *
FROM addresses
USING SAMPLE 1%;
```

Select a sample of 1% of the addresses table using bernoulli sampling:

```
SELECT *
FROM addresses
USING SAMPLE 1% (bernoulli);
```

Select a sample of 10 rows from the subquery:

```
SELECT *
FROM (SELECT * FROM addresses)
USING SAMPLE 10 ROWS;
```

Syntax

Unnesting

Examples

Unnest a list, generating 3 rows (1, 2, 3):

```
SELECT unnest([1, 2, 3]);
```

Unnesting a struct, generating two columns (a, b):

```
SELECT unnest({'a': 42, 'b': 84});
```

Recursive unnest of a list of structs:

```
SELECT unnest([{'a': 42, 'b': 84}, {'a': 100, 'b': NULL}], recursive := true);
```

Limit depth of recursive unnest using `max_depth`:

```
SELECT unnest([[[1, 2], [3, 4]], [[5, 6], [7, 8, 9], []], [[10, 11]]], max_depth := 2);
```

The `unnest` special function is used to unnest lists or structs by one level. The function can be used as a regular scalar function, but only in the SELECT clause. Invoking `unnest` with the `recursive` parameter will unnest lists and structs of multiple levels. The depth of unnesting can be limited using the `max_depth` parameter (which assumes `recursive` unnesting by default).

Unnesting Lists

Unnest a list, generating 3 rows (1, 2, 3):

```
SELECT unnest([1, 2, 3]);
```

Unnest a list, generating 3 rows ((1, 10), (2, 10), (3, 10)):

```
SELECT unnest([1, 2, 3]), 10;
```

Unnest two lists of different sizes, generating 3 rows ((1, 10), (2, 11), (3, NULL)):

```
SELECT unnest([1, 2, 3]), unnest([10, 11]);
```

Unnest a list column from a subquery:

```
SELECT unnest(l) + 10 FROM (VALUES ([1, 2, 3]), ([4, 5])) tbl(l);
```

Empty result:

```
SELECT unnest([]);
```

Empty result:

```
SELECT unnest(NULL);
```

Using `unnest` on a list emits one row per list entry. Regular scalar expressions in the same `SELECT` clause are repeated for every emitted row. When multiple lists are unnested in the same `SELECT` clause, the lists are unnested side-by-side. If one list is longer than the other, the shorter list is padded with `NULL` values.

Empty and `NULL` lists both unnest to zero rows.

Unnesting Structs

Unnesting a struct, generating two columns (a, b):

```
SELECT unnest({'a': 42, 'b': 84});
```

Unnesting a struct, generating two columns (a, b):

```
SELECT unnest({'a': 42, 'b': {'x': 84}});
```

`unnest` on a struct will emit one column per entry in the struct.

Recursive Unnest

Unnesting a list of lists recursively, generating 5 rows (1, 2, 3, 4, 5):

```
SELECT unnest([[1, 2, 3], [4, 5]], recursive := true);
```

Unnesting a list of structs recursively, generating two rows of two columns (a, b):

```
SELECT unnest([{'a': 42, 'b': 84}, {'a': 100, 'b': NULL}], recursive := true);
```

Unnesting a struct, generating two columns (a, b):

```
SELECT unnest({'a': [1, 2, 3], 'b': 88}, recursive := true);
```

Calling `unnest` with the `recursive` setting will fully unnest lists, followed by fully unnesting structs. This can be useful to fully flatten columns that contain lists within lists, or lists of structs. Note that lists *within* structs are not unnested.

Setting the Maximum Depth of Unnesting

The `max_depth` parameter allows limiting the maximum depth of recursive unnesting (which is assumed by default and does not have to be specified separately). For example, unnesting to `max_depth` of 2 yields the following:

```
SELECT unnest([[[1, 2], [3, 4]], [[5, 6], [7, 8, 9], []], [[10, 11]]], max_depth := 2) AS x;
```

x
[1, 2]
[3, 4]
[5, 6]
[7, 8, 9]
[]
[10, 11]

Meanwhile, unnesting to `max_depth` of 3 results in:

```
SELECT unnest([[[1, 2], [3, 4]], [[5, 6], [7, 8, 9], []], [[10, 11]]], max_depth := 3) AS x;
```

x
1
2
3
4
5
6
7
8
9
10
11

Keeping Track of List Entry Positions

To keep track of each entry's position within the original list, `unnest` may be combined with `generate_subscripts`:

```
SELECT unnest(l) AS x, generate_subscripts(l, 1) AS index
FROM (VALUES ([1, 2, 3]), ([4, 5])) tbl(l);
```

x	index
1	1
2	2
3	3
4	1

x	index
5	2

Keep Column Names When Recursively Unnesting

The `keep_parent_names` parameter can be used to retain the parent column names when recursively unnesting a named struct. For example, unnesting the following query with `keep_parent_names` enabled:

```
SELECT unnest([{'a': 0, 'b': {'bb': {'bbb': 1}}}], recursive := true, keep_parent_names := true);
```

yields the following result:

a	b.bb.bbb
0	1

In this case, the field names are preserved, showing the path to the innermost value. This is particularly useful when working with complex nested data structures, as it maintains the structure and naming convention of the original data. The parameter can also be used in conjunction with the `max_depth` parameter, allowing more control and enabling more precise management of nested structures.

WITH Clause

The `WITH` clause allows you to specify common table expressions (CTEs). Regular (non-recursive) common-table-expressions are essentially views that are limited in scope to a particular query. CTEs can reference each other and can be nested. Recursive CTEs can reference themselves.

Basic CTE Examples

Create a CTE called `cte` and use it in the main query:

```
WITH cte AS (SELECT 42 AS x)
SELECT * FROM cte;
```

x
42

Create two CTEs `cte1` and `cte2`, where the second CTE references the first CTE:

```
WITH
    cte1 AS (SELECT 42 AS i),
    cte2 AS (SELECT i * 100 AS x FROM cte1)
SELECT * FROM cte2;
```

x
4200

You can specify column names for CTEs:

```
WITH cte(j) AS (SELECT 42 AS i)
FROM cte;
```

CTE Materialization

DuckDB handles CTEs as *materialized* by default, meaning that the CTE is evaluated once and the result is stored in a temporary table. However, under certain conditions, DuckDB can *inline* the CTE into the main query, which means that the CTE is not materialized and its definition is duplicated in each place it is referenced. Inlining is done using the following heuristics:

- The CTE is not referenced more than once.
- The CTE does not contain a `VOLATILE` function.
- The CTE is using `AS NOT MATERIALIZED` and does not use `AS MATERIALIZED`.
- The CTE does not perform a grouped aggregation.

Materialization can be explicitly activated by defining the CTE using `AS MATERIALIZED` and disabled by using `AS NOT MATERIALIZED`. Note that inlining is not always possible, even if the heuristics are met. For example, if the CTE contains a `read_csv` function, it cannot be inlined.

Take the following query for example, which invokes the same CTE three times:

```
WITH t(x) AS (<complex_query>)
SELECT *
FROM
    t AS t1,
    t AS t2,
    t AS t3;
```

Inlining duplicates the definition of `t` for each reference which results in the following query:

```
SELECT *
FROM
    (<complex_query>) AS t1(x),
    (<complex_query>) AS t2(x),
    (<complex_query>) AS t3(x);
```

If `complex_query` is expensive, materializing it with the `MATERIALIZED` keyword can improve performance. In this case, `complex_query` is evaluated only once.

```
WITH t(x) AS MATERIALIZED (<complex_query>)
SELECT *
FROM
    t AS t1,
    t AS t2,
    t AS t3;
```

If one wants to disable materialization, use `NOT MATERIALIZED`:

```
WITH t(x) AS NOT MATERIALIZED (<complex_query>)
SELECT *
FROM
    t AS t1,
    t AS t2,
    t AS t3;
```

Generally, it is not recommended to use explicit materialization hints, as DuckDB's query optimizer is capable of deciding when to materialize or inline a CTE based on the query structure and the heuristics mentioned above. However, in some cases, it may be beneficial to use `MATERIALIZED` or `NOT MATERIALIZED` to control the behavior explicitly.

Recursive CTEs

`WITH RECURSIVE` allows the definition of CTEs which can refer to themselves. Note that the query must be formulated in a way that ensures termination, otherwise, it may run into an infinite loop.

Example: Fibonacci Sequence

`WITH RECURSIVE` can be used to make recursive calculations. For example, here is how `WITH RECURSIVE` could be used to calculate the first ten Fibonacci numbers:

```
WITH RECURSIVE FibonacciNumbers (
    RecursionDepth, FibonacciNumber, NextNumber
) AS (
        -- Base case
        SELECT
            0 AS RecursionDepth,
            0 AS FibonacciNumber,
            1 AS NextNumber
        UNION ALL
        -- Recursive step
        SELECT
            fib.RecursionDepth + 1 AS RecursionDepth,
            fib.NextNumber AS FibonacciNumber,
            fib.FibonacciNumber + fib.NextNumber AS NextNumber
        FROM
            FibonacciNumbers fib
        WHERE
            fib.RecursionDepth + 1 < 10
    )
SELECT
    fn.RecursionDepth AS FibonacciNumberIndex,
    fn.FibonacciNumber
FROM
    FibonacciNumbers fn;
```

FibonacciNumberIndex	FibonacciNumber
0	0
1	1
2	1
3	2
4	3
5	5
6	8
7	13
8	21
9	34

Example: Tree Traversal

`WITH RECURSIVE` can be used to traverse trees. For example, take a hierarchy of tags:

```
CREATE TABLE tag (id INTEGER, name VARCHAR, subclassof INTEGER);
INSERT INTO tag VALUES
    (1, 'U2',     5),
    (2, 'Blur',   5),
    (3, 'Oasis',  5),
    (4, '2Pac',   6),
    (5, 'Rock',   7),
```

```
    (6, 'Rap',    7),
    (7, 'Music',  9),
    (8, 'Movies', 9),
    (9, 'Art', NULL);
```

The following query returns the path from the node `Oasis` to the root of the tree (`Art`).

```
WITH RECURSIVE tag_hierarchy(id, source, path) AS (
        SELECT id, name, [name] AS path
        FROM tag
        WHERE subclassof IS NULL
    UNION ALL
        SELECT tag.id, tag.name, list_prepend(tag.name, tag_hierarchy.path)
        FROM tag, tag_hierarchy
        WHERE tag.subclassof = tag_hierarchy.id
    )
SELECT path
FROM tag_hierarchy
WHERE source = 'Oasis';
```

path
[Oasis, Rock, Music, Art]

Graph Traversal

The `WITH RECURSIVE` clause can be used to express graph traversal on arbitrary graphs. However, if the graph has cycles, the query must perform cycle detection to prevent infinite loops. One way to achieve this is to store the path of a traversal in a list and, before extending the path with a new edge, check whether its endpoint has been visited before (see the example later).

Take the following directed graph from the LDBC Graphalytics benchmark:

```
CREATE TABLE edge (node1id INTEGER, node2id INTEGER);
INSERT INTO edge VALUES
    (1, 3), (1, 5), (2, 4), (2, 5), (2, 10), (3, 1),
    (3, 5), (3, 8), (3, 10), (5, 3), (5, 4), (5, 8),
    (6, 3), (6, 4), (7, 4), (8, 1), (9, 4);
```

Note that the graph contains directed cycles, e.g., between nodes 1, 5 and 8.

Enumerate All Paths from a Node The following query returns **all paths** starting in node 1:

```
WITH RECURSIVE paths(startNode, endNode, path) AS (
        SELECT -- Define the path as the first edge of the traversal
            node1id AS startNode,
            node2id AS endNode,
            [node1id, node2id] AS path
        FROM edge
        WHERE startNode = 1
        UNION ALL
        SELECT -- Concatenate new edge to the path
            paths.startNode AS startNode,
            node2id AS endNode,
            array_append(path, node2id) AS path
        FROM paths
        JOIN edge ON paths.endNode = node1id
        -- Prevent adding a repeated node to the path.
        -- This ensures that no cycles occur.
```

```
        WHERE list_position(paths.path, node2id) IS NULL
    )
SELECT startNode, endNode, path
FROM paths
ORDER BY length(path), path;
```

startNode	endNode	path
1	3	[1, 3]
1	5	[1, 5]
1	5	[1, 3, 5]
1	8	[1, 3, 8]
1	10	[1, 3, 10]
1	3	[1, 5, 3]
1	4	[1, 5, 4]
1	8	[1, 5, 8]
1	4	[1, 3, 5, 4]
1	8	[1, 3, 5, 8]
1	8	[1, 5, 3, 8]
1	10	[1, 5, 3, 10]

Note that the result of this query is not restricted to shortest paths, e.g., for node 5, the results include paths `[1, 5]` and `[1, 3, 5]`.

Enumerate Unweighted Shortest Paths from a Node In most cases, enumerating all paths is not practical or feasible. Instead, only the **(unweighted) shortest paths** are of interest. To find these, the second half of the `WITH RECURSIVE` query should be adjusted such that it only includes a node if it has not yet been visited. This is implemented by using a subquery that checks if any of the previous paths includes the node:

```
WITH RECURSIVE paths(startNode, endNode, path) AS (
        SELECT -- Define the path as the first edge of the traversal
            node1id AS startNode,
            node2id AS endNode,
            [node1id, node2id] AS path
        FROM edge
        WHERE startNode = 1
        UNION ALL
        SELECT -- Concatenate new edge to the path
            paths.startNode AS startNode,
            node2id AS endNode,
            array_append(path, node2id) AS path
        FROM paths
        JOIN edge ON paths.endNode = node1id
        -- Prevent adding a node that was visited previously by any path.
        -- This ensures that (1) no cycles occur and (2) only nodes that
        -- were not visited by previous (shorter) paths are added to a path.
        WHERE NOT EXISTS (
                FROM paths previous_paths
                WHERE list_contains(previous_paths.path, node2id)
              )
    )
SELECT startNode, endNode, path
FROM paths
ORDER BY length(path), path;
```

startNode	endNode	path
1	3	[1, 3]
1	5	[1, 5]
1	8	[1, 3, 8]
1	10	[1, 3, 10]
1	4	[1, 5, 4]
1	8	[1, 5, 8]

Enumerate Unweighted Shortest Paths between Two Nodes `WITH RECURSIVE` can also be used to find **all (unweighted) shortest paths between two nodes**. To ensure that the recursive query is stopped as soon as we reach the end node, we use a window function which checks whether the end node is among the newly added nodes.

The following query returns all unweighted shortest paths between nodes 1 (start node) and 8 (end node):

```
WITH RECURSIVE paths(startNode, endNode, path, endReached) AS (
   SELECT -- Define the path as the first edge of the traversal
        node1id AS startNode,
        node2id AS endNode,
        [node1id, node2id] AS path,
        (node2id = 8) AS endReached
     FROM edge
     WHERE startNode = 1
   UNION ALL
   SELECT -- Concatenate new edge to the path
        paths.startNode AS startNode,
        node2id AS endNode,
        array_append(path, node2id) AS path,
        max(CASE WHEN node2id = 8 THEN 1 ELSE 0 END)
            OVER (ROWS BETWEEN UNBOUNDED PRECEDING
                           AND UNBOUNDED FOLLOWING) AS endReached
     FROM paths
     JOIN edge ON paths.endNode = node1id
    WHERE NOT EXISTS (
            FROM paths previous_paths
            WHERE list_contains(previous_paths.path, node2id)
          )
      AND paths.endReached = 0
)
SELECT startNode, endNode, path
FROM paths
WHERE endNode = 8
ORDER BY length(path), path;
```

startNode	endNode	path
1	8	[1, 3, 8]
1	8	[1, 5, 8]

Accessing the Union Table with `recurring`

Within the recursive term of a `WITH RECURSIVE` CTE, the CTE name (e.g., `counter`) refers to the rows produced by the *last iteration*. To access *all rows accumulated so far* (the union table), use the `recurring` schema prefix:

```
WITH RECURSIVE counter(i) AS (
    SELECT 1
        UNION ALL
    SELECT i + 1
    FROM counter
    WHERE (SELECT max(i) FROM recurring.counter) < 5
)
SELECT *
FROM counter;
```

i
1
2
3
4
5

Here, `recurring.counter` gives access to all rows accumulated across all previous iterations, while `counter` in the `FROM` clause only contains the rows from the most recent iteration. This is useful when termination conditions or calculations depend on the full accumulated result rather than just the previous iteration.

Recursive CTEs with `USING KEY`

> **Deprecated.** DuckDB 1.5.0 deprecated the use of recursive `UNION`s for `USING KEY` CTEs in favor of recursive `UNION ALL`s.
>
> The recursive `UNION`s imply that not all rows that are produced in one iteration are passed to the next, as would be the case for regular recursive CTEs. Since the opposite is true, i.e., all rows are passed from one iteration to the next, going forward DuckDB's `USING KEY` CTEs will require recursive `UNION ALL`s instead.
>
> DuckDB 1.5.0 also introduces a new setting to configure the `USING KEY` syntax.
>
> ```
> SET deprecated_using_key_syntax = 'DEFAULT';
> SET deprecated_using_key_syntax = 'UNION_AS_UNION_ALL';
> ```
>
> Currently, `DEFAULT` enables both syntax styles, i.e., allows both recursive `UNION`s and recursive `UNION ALL`s in `USING KEY` CTEs.
>
> DuckDB 1.5.0 will be the last release supporting the `UNION` syntax without explicitly enabling it.
>
> DuckDB 2.0.0 disables the `UNION` syntax by default.
>
> DuckDB 2.1.0 removes the `deprecated_using_key_syntax` flag and fully deprecates the `UNION` syntax.

`USING KEY` alters the behavior of a regular recursive CTE.

In each iteration, a regular recursive CTE appends result rows to the union table, which ultimately defines the overall result of the CTE. In contrast, a CTE with `USING KEY` has the ability to update rows that have been placed in the union table in an earlier iteration: if the current iteration produces a row with key k, it replaces a row with the same key k in the union table (like a dictionary). If no such row exists in the union table yet, the new row is appended to the union table as usual.

This allows a CTE to exercise fine-grained control over the union table contents. Avoiding the append-only behavior can lead to significantly smaller union table sizes. This helps query runtime, memory consumption, and makes it feasible to access the union table while the iteration is still ongoing. In a CTE `WITH RECURSIVE T(...) USING KEY ...`, table `T` denotes the rows added by the last iteration (as is usual for recursive CTEs), while table `recurring.T` denotes the union table built so far. References to `recurring.T` allow for the elegant and idiomatic translation of rather complex algorithms into readable SQL code.

Example: `USING KEY`

This is a recursive CTE where `USING KEY` has a key column (a) and a payload column (b). The payload columns correspond to the columns to be overwritten. In the first iteration we have two different keys, 1 and 2. These two keys will generate two new rows, `(1, 3)` and `(2, 4)`. In the next iteration we produce a new key, 3, which generates a new row. We also generate the row `(2, 3)`, where 2 is a key that already exists from the previous iteration. This will overwrite the old payload 4 with the new payload 3.

```
WITH RECURSIVE tbl(a, b) USING KEY (a) AS (
    SELECT a, b
    FROM (VALUES (1, 3), (2, 4)) t(a, b)
        UNION ALL
    SELECT a + 1, b
    FROM tbl
    WHERE a < 3
)
SELECT *
FROM tbl;
```

a	b
1	3
2	3
3	3

Using VALUES

You can use the VALUES clause for the initial (anchor) part of the CTE:

```
WITH RECURSIVE tbl(a, b) USING KEY (a) AS (
    VALUES (1, 3), (2, 4)
        UNION ALL
    SELECT a + 1, b
    FROM tbl
    WHERE a < 3
)
SELECT *
FROM tbl;
```

Example: `USING KEY` References Union Table

As well as using the union table as a dictionary, we can now reference it in queries. This allows you to use results from not just the previous iteration, but also earlier ones. This new feature makes certain algorithms easier to implement.

One example is the connected components algorithm. For each node, the algorithm determines the node with the lowest ID to which it is connected. To achieve this, we use the entries in the union table to track the lowest ID found for a node. If a new incoming row contains a lower ID, we update this value.

```
CREATE TABLE nodes (id INTEGER);
INSERT INTO nodes VALUES (1), (2), (3), (4), (5), (6), (7), (8);
CREATE TABLE edges (node1id INTEGER, node2id INTEGER);
INSERT INTO edges VALUES
    (1, 3), (2, 3), (3, 7), (7, 8), (5, 4), (6, 4);

WITH RECURSIVE connected_components(id, comp) USING KEY (id) AS (
    SELECT n.id, n.id AS comp
    FROM nodes AS n
```

```
        UNION ALL (
    SELECT DISTINCT ON (previous_iter.id) previous_iter.id, initial_iter.comp
    FROM
        recurring.connected_components AS previous_iter,
        connected_components AS initial_iter,
        edges AS e
    WHERE ((e.node1id, e.node2id) = (previous_iter.id, initial_iter.id)
       OR (e.node2id, e.node1id) = (previous_iter.id, initial_iter.id))
      AND initial_iter.comp < previous_iter.comp
    ORDER BY initial_iter.id ASC, previous_iter.comp ASC)
)
TABLE connected_components
ORDER BY id;
```

id	comp
1	1
2	1
3	1
4	4
5	4
6	4
7	1
8	1

Limitations

DuckDB does not support mutually recursive CTEs. See the related issue and discussion in the DuckDB repository.

Syntax

WINDOW Clause

The `WINDOW` clause allows you to specify named windows that can be used within window functions. These are useful when you have multiple window functions, as they allow you to avoid repeating the same window clause.

Syntax

QUALIFY Clause

The `QUALIFY` clause is used to filter the results of `WINDOW` functions. This filtering of results is similar to how a `HAVING` clause filters the results of aggregate functions applied based on the `GROUP BY` clause.

The `QUALIFY` clause avoids the need for a subquery or `WITH` clause to perform this filtering (much like `HAVING` avoids a subquery). An example using a `WITH` clause instead of `QUALIFY` is included below the `QUALIFY` examples.

Note that this is filtering based on `WINDOW` functions, not necessarily based on the `WINDOW` clause. The `WINDOW` clause is optional and can be used to simplify the creation of multiple `WINDOW` function expressions.

The position of where to specify a `QUALIFY` clause is following the `WINDOW` clause in a `SELECT` statement (`WINDOW` does not need to be specified), and before the `ORDER BY`.

Examples

Each of the following examples produce the same output, located below.

Filter based on a window function defined in the `QUALIFY` clause:

```
SELECT
    schema_name,
    function_name,
    -- In this example the function_rank column in the select clause is for reference
    row_number() OVER (PARTITION BY schema_name ORDER BY function_name) AS function_rank
FROM duckdb_functions()
QUALIFY
    row_number() OVER (PARTITION BY schema_name ORDER BY function_name) < 3;
```

Filter based on a window function defined in the `SELECT` clause:

```
SELECT
    schema_name,
    function_name,
    row_number() OVER (PARTITION BY schema_name ORDER BY function_name) AS function_rank
FROM duckdb_functions()
QUALIFY
    function_rank < 3;
```

Filter based on a window function defined in the `QUALIFY` clause, but using the `WINDOW` clause:

```
SELECT
    schema_name,
    function_name,
    -- In this example the function_rank column in the select clause is for reference
    row_number() OVER my_window AS function_rank
FROM duckdb_functions()
WINDOW
    my_window AS (PARTITION BY schema_name ORDER BY function_name)
QUALIFY
    row_number() OVER my_window < 3;
```

Filter based on a window function defined in the `SELECT` clause, but using the `WINDOW` clause:

```
SELECT
    schema_name,
    function_name,
    row_number() OVER my_window AS function_rank
FROM duckdb_functions()
WINDOW
    my_window AS (PARTITION BY schema_name ORDER BY function_name)
QUALIFY
    function_rank < 3;
```

Equivalent query based on a `WITH` clause (without a `QUALIFY` clause):

```
WITH ranked_functions AS (
    SELECT
        schema_name,
        function_name,
        row_number() OVER (PARTITION BY schema_name ORDER BY function_name) AS function_rank
    FROM duckdb_functions()
)
SELECT
    *
FROM ranked_functions
```

```
WHERE
    function_rank < 3;
```

schema_name	function_name	function_rank
main	!__postfix	1
main	!~~	2
pg_catalog	col_description	1
pg_catalog	format_pg_type	2

Syntax

VALUES Clause

The `VALUES` clause is used to specify a fixed number of rows. The `VALUES` clause can be used as a stand-alone statement, as part of the `FROM` clause, or as input to an `INSERT INTO` statement.

Examples

Generate two rows and directly return them:

```
VALUES ('Amsterdam', 1), ('London', 2);
```

Generate two rows as part of a `FROM` clause, and rename the columns:

```
SELECT *
FROM (VALUES ('Amsterdam', 1), ('London', 2)) cities(name, id);
```

Generate two rows and insert them into a table:

```
INSERT INTO cities
VALUES ('Amsterdam', 1), ('London', 2);
```

Create a table directly from a `VALUES` clause:

```
CREATE TABLE cities AS
    SELECT *
    FROM (VALUES ('Amsterdam', 1), ('London', 2)) cities(name, id);
```

Syntax

FILTER Clause

The `FILTER` clause may optionally follow an aggregate function in a `SELECT` statement. This will filter the rows of data that are fed into the aggregate function in the same way that a `WHERE` clause filters rows, but localized to the specific aggregate function.

There are multiple types of situations where this is useful, including when evaluating multiple aggregates with different filters, and when creating a pivoted view of a dataset. `FILTER` provides a cleaner syntax for pivoting data when compared with the more traditional `CASE WHEN` approach discussed below.

Some aggregate functions also do not filter out `NULL` values, so using a `FILTER` clause will return valid results when at times the `CASE WHEN` approach will not. This occurs with the functions `first` and `last`, which are desirable in a non-aggregating pivot operation where the goal is to simply re-orient the data into columns rather than re-aggregate it. `FILTER` also improves `NULL` handling when using the `list` and `array_agg` functions, as the `CASE WHEN` approach will include `NULL` values in the list result, while the `FILTER` clause will remove them.

Examples

Return the following:

- The total number of rows
- The number of rows where `i <= 5`
- The number of rows where `i` is odd

```
SELECT
    count() AS total_rows,
    count() FILTER (i <= 5) AS lte_five,
    count() FILTER (i % 2 = 1) AS odds
FROM generate_series(1, 10) tbl(i);
```

total_rows	lte_five	odds
10	5	5

> Simply counting rows that satisfy a condition can also be achieved without the `FILTER` clause, using the boolean `sum` aggregate function, e.g., `sum(i <= 5)`.

Different aggregate functions may be used, and multiple `WHERE` expressions are also permitted:

```
SELECT
    sum(i) FILTER (i <= 5) AS lte_five_sum,
    median(i) FILTER (i % 2 = 1) AS odds_median,
    median(i) FILTER (i % 2 = 1 AND i <= 5) AS odds_lte_five_median
FROM generate_series(1, 10) tbl(i);
```

lte_five_sum	odds_median	odds_lte_five_median
15	5.0	3.0

The `FILTER` clause can also be used to pivot data from rows into columns. This is a static pivot, as columns must be defined prior to runtime in SQL. However, this kind of statement can be dynamically generated in a host programming language to leverage DuckDB's SQL engine for rapid, larger than memory pivoting.

First generate an example dataset:

```
CREATE TEMP TABLE stacked_data AS
    SELECT
        i,
        CASE WHEN i <= rows * 0.25  THEN 2022
             WHEN i <= rows * 0.5   THEN 2023
             WHEN i <= rows * 0.75  THEN 2024
             WHEN i <= rows * 0.875 THEN 2025
             ELSE NULL
             END AS year
    FROM (
        SELECT
            i,
            count(*) OVER () AS rows
        FROM generate_series(1, 100_000_000) tbl(i)
    ) tbl;
```

"Pivot" the data out by year (move each year out to a separate column):

```
SELECT
    count(i) FILTER (year = 2022) AS "2022",
    count(i) FILTER (year = 2023) AS "2023",
    count(i) FILTER (year = 2024) AS "2024",
    count(i) FILTER (year = 2025) AS "2025",
    count(i) FILTER (year IS NULL) AS "NULLs"
FROM stacked_data;
```

This syntax produces the same results as the `FILTER` clauses above:

```
SELECT
    count(CASE WHEN year = 2022 THEN i END) AS "2022",
    count(CASE WHEN year = 2023 THEN i END) AS "2023",
    count(CASE WHEN year = 2024 THEN i END) AS "2024",
    count(CASE WHEN year = 2025 THEN i END) AS "2025",
    count(CASE WHEN year IS NULL THEN i END) AS "NULLs"
FROM stacked_data;
```

2022	2023	2024	2025	NULLs
25000000	25000000	25000000	12500000	12500000

However, the `CASE WHEN` approach will not work as expected when using an aggregate function that does not ignore `NULL` values. The `first` function falls into this category, so `FILTER` is preferred in this case.

"Pivot" the data out by year (move each year out to a separate column):

```
SELECT
    first(i) FILTER (year = 2022) AS "2022",
    first(i) FILTER (year = 2023) AS "2023",
    first(i) FILTER (year = 2024) AS "2024",
    first(i) FILTER (year = 2025) AS "2025",
    first(i) FILTER (year IS NULL) AS "NULLs"
FROM stacked_data;
```

2022	2023	2024	2025	NULLs
1474561	25804801	50749441	76431361	87500001

This will produce `NULL` values whenever the first evaluation of the `CASE WHEN` clause returns a `NULL`:

```
SELECT
    first(CASE WHEN year = 2022 THEN i END) AS "2022",
    first(CASE WHEN year = 2023 THEN i END) AS "2023",
    first(CASE WHEN year = 2024 THEN i END) AS "2024",
    first(CASE WHEN year = 2025 THEN i END) AS "2025",
    first(CASE WHEN year IS NULL THEN i END) AS "NULLs"
FROM stacked_data;
```

2022	2023	2024	2025	NULLs
1228801	NULL	NULL	NULL	NULL

Aggregate Function Syntax (Including `FILTER` Clause)

Set Operations

Set operations allow queries to be combined according to set operation semantics. Set operations refer to the `UNION [ALL]`, `INTERSECT [ALL]` and `EXCEPT [ALL]` clauses. The vanilla variants use set semantics, i.e., they eliminate duplicates, while the variants with `ALL` use bag semantics.

Traditional set operations unify queries **by column position**, and require the to-be-combined queries to have the same number of input columns. If the columns are not of the same type, casts may be added. The result will use the column names from the first query.

DuckDB also supports `UNION [ALL] BY NAME`, which joins columns by name instead of by position. `UNION BY NAME` does not require the inputs to have the same number of columns. `NULL` values will be added in case of missing columns.

`UNION`

The `UNION` clause can be used to combine rows from multiple queries. The queries are required to return the same number of columns. Implicit casting to one of the returned types is performed to combine columns of different types where necessary. If this is not possible, the `UNION` clause throws an error.

Vanilla `UNION` (Set Semantics)

The vanilla `UNION` clause follows set semantics, therefore it performs duplicate elimination, i.e., only unique rows will be included in the result.

```
SELECT * FROM range(2) t1(x)
UNION
SELECT * FROM range(3) t2(x);
```

x
2
1
0

`UNION ALL` (Bag Semantics)

`UNION ALL` returns all rows of both queries following bag semantics, i.e., *without* duplicate elimination.

```
SELECT * FROM range(2) t1(x)
UNION ALL
SELECT * FROM range(3) t2(x);
```

x
0
1
0
1
2

`UNION [ALL] BY NAME`

The `UNION [ALL] BY NAME` clause can be used to combine rows from different tables by name, instead of by position. `UNION BY NAME` does not require both queries to have the same number of columns. Any columns that are only found in one of the queries are filled with `NULL` values for the other query.

Take the following tables for example:

```
CREATE TABLE capitals (city VARCHAR, country VARCHAR);
INSERT INTO capitals VALUES
    ('Amsterdam', 'NL'),
    ('Berlin', 'Germany');
CREATE TABLE weather (city VARCHAR, degrees INTEGER, date DATE);
INSERT INTO weather VALUES
    ('Amsterdam', 10, '2022-10-14'),
    ('Seattle', 8, '2022-10-12');

SELECT * FROM capitals
UNION BY NAME
SELECT * FROM weather;
```

city	country	degrees	date
Seattle	NULL	8	2022-10-12
Amsterdam	NL	NULL	NULL
Berlin	Germany	NULL	NULL
Amsterdam	NULL	10	2022-10-14

`UNION BY NAME` follows set semantics (therefore it performs duplicate elimination), whereas `UNION ALL BY NAME` follows bag semantics.

`INTERSECT`

The `INTERSECT` clause can be used to select all rows that occur in the result of **both** queries.

Vanilla `INTERSECT` (Set Semantics)

Vanilla `INTERSECT` performs duplicate elimination, so only unique rows are returned.

```
SELECT * FROM range(2) t1(x)
INTERSECT
SELECT * FROM range(6) t2(x);
```

x
0
1

`INTERSECT ALL` (Bag Semantics)

`INTERSECT ALL` follows bag semantics, so duplicates are returned.

```
SELECT unnest([5, 5, 6, 6, 6, 6, 7, 8]) AS x
INTERSECT ALL
SELECT unnest([5, 6, 6, 7, 7, 9]);
```

x
5
6
6
7

EXCEPT

The EXCEPT clause can be used to select all rows that **only** occur in the left query.

Vanilla EXCEPT (Set Semantics)

Vanilla EXCEPT follows set semantics, therefore, it performs duplicate elimination, so only unique rows are returned.

```
SELECT * FROM range(5) t1(x)
EXCEPT
SELECT * FROM range(2) t2(x);
```

x
2
3
4

EXCEPT ALL (Bag Semantics)

EXCEPT ALL uses bag semantics:

```
SELECT unnest([5, 5, 6, 6, 6, 6, 7, 8]) AS x
EXCEPT ALL
SELECT unnest([5, 6, 6, 7, 7, 9]);
```

x
5
8
6
6

Syntax

Prepared Statements

DuckDB supports prepared statements where parameters are substituted when the query is executed. This can improve readability and is useful for preventing SQL injections.

Syntax

There are three syntaxes for denoting parameters in prepared statements: auto-incremented (`?`), positional (`$1`), and named (`$param`). Note that not all clients support all of these syntaxes, e.g., the JDBC client only supports auto-incremented parameters in prepared statements.

Example Dataset

In the following, we introduce the three different syntaxes and illustrate them with examples using the following table.

```
CREATE TABLE person (name VARCHAR, age BIGINT);
INSERT INTO person VALUES ('Alice', 37), ('Ana', 35), ('Bob', 41), ('Bea', 25);
```

In our example query, we'll look for people whose name starts with a B and are at least 40 years old. This will return a single row `<'Bob', 41>`.

Auto-Incremented Parameters: ?

DuckDB supports using prepared statements with auto-incremented indexing, i.e., the position of the parameters in the query corresponds to their position in the execution statement. For example:

```
PREPARE query_person AS
    SELECT *
    FROM person
    WHERE starts_with(name, ?)
      AND age >= ?;
```

Using the CLI client, the statement is executed as follows.

```
EXECUTE query_person('B', 40);
```

Positional Parameters: $1

Prepared statements can use positional parameters, where parameters are denoted with an integer (`$1`, `$2`). For example:

```
PREPARE query_person AS
    SELECT *
    FROM person
    WHERE starts_with(name, $2)
      AND age >= $1;
```

Using the CLI client, the statement is executed as follows. Note that the first parameter corresponds to `$1`, the second to `$2`, and so on.

```
EXECUTE query_person(40, 'B');
```

Named Parameters: `$parameter`

DuckDB also supports named parameters where parameters are denoted with `$parameter_name`. For example:

```
PREPARE query_person AS
    SELECT *
    FROM person
    WHERE starts_with(name, $name_start_letter)
      AND age >= $minimum_age;
```

Using the CLI client, the statement is executed as follows.

```
EXECUTE query_person(name_start_letter := 'B', minimum_age := 40);
```

Dropping Prepared Statements: DEALLOCATE

To drop a prepared statement, use the `DEALLOCATE` statement:

```
DEALLOCATE query_person;
```

Alternatively, use:

```
DEALLOCATE PREPARE query_person;
```

Data Types

Data Types

General-Purpose Data Types

The table below shows all the built-in general-purpose data types. The alternatives listed in the aliases column can be used to refer to these types as well, however, note that the aliases are not part of the SQL standard and hence might not be accepted by other database engines.

Name	Aliases	Description
`BIGINT`	`INT8`, `LONG`	Signed eight-byte integer
`BIT`	`BITSTRING`	String of 1s and 0s
`BLOB`	`BYTEA`, `BINARY`, `VARBINARY`	Variable-length binary data
`BIGNUM`		Variable-length integer
`BOOLEAN`	`BOOL`, `LOGICAL`	Logical Boolean (`true` / `false`)
`DATE`		Calendar date (year, month, day)
`DECIMAL(prec, scale)`	`NUMERIC(prec, scale)`	Fixed-precision number with the given width (precision) and scale, defaults to `prec = 18` and `scale = 3`
`DOUBLE`	`FLOAT8`	Double precision floating-point number (8 bytes)
`FLOAT`	`FLOAT4`, `REAL`	Single precision floating-point number (4 bytes)
`HUGEINT`		Signed sixteen-byte integer
`INTEGER`	`INT4`, `INT`, `SIGNED`	Signed four-byte integer
`INTERVAL`		Date / time delta
`JSON`		JSON object (via the `json` extension)
`SMALLINT`	`INT2`, `SHORT`	Signed two-byte integer
`TIME`		Time of day (no time zone)
`TIMESTAMP WITH TIME ZONE`	`TIMESTAMPTZ`	Combination of time and date that uses the current time zone
`TIMESTAMP`	`DATETIME`	Combination of time and date
`TINYINT`	`INT1`	Signed one-byte integer
`UBIGINT`		Unsigned eight-byte integer
`UHUGEINT`		Unsigned sixteen-byte integer
`UINTEGER`		Unsigned four-byte integer
`USMALLINT`		Unsigned two-byte integer
`UTINYINT`		Unsigned one-byte integer
`UUID`		UUID data type

Name	Aliases	Description
VARCHAR	CHAR, BPCHAR, TEXT, STRING	Variable-length character string

Implicit and explicit typecasting is possible between numerous types, see the Typecasting page for details.

Nested / Composite Types

DuckDB supports five nested data types: `ARRAY`, `LIST`, `MAP`, `STRUCT` and `UNION`. Each supports different use cases and has a different structure.

Name	Description	Rules when used in a column	Build from values	Define in DDL/CREATE
ARRAY	An ordered, fixed-length sequence of data values of the same type.	Each row must have the same data type within each instance of the ARRAY and the same number of elements.	`[1, 2, 3]`	`INTEGER[3]`
LIST	An ordered sequence of data values of the same type.	Each row must have the same data type within each instance of the LIST, but can have any number of elements.	`[1, 2, 3]`	`INTEGER[]`
MAP	A dictionary of multiple named values, each key having the same type and each value having the same type. Keys and values can be any type and can be different types from one another.	Rows may have different keys.	`map([1, 2], ['a', 'b'])`	`MAP(INTEGER, VARCHAR)`
STRUCT	A dictionary of multiple named values, where each key is a string, but the value can be a different type for each key.	Each row must have the same keys.	`{'i': 42, 'j': 'a'}`	`STRUCT(i INTEGER, j VARCHAR)`
UNION	A union of multiple alternative data types, storing one of them in each value at a time. A union also contains a discriminator "tag" value to inspect and access the currently set member type.	Rows may be set to different member types of the union.	`union_value(num := 2)`	`UNION(num INTEGER, text VARCHAR)`
VARIANT	A semi-structured type where each value is self-contained with its own type information.	Each row may hold a value of a different type.	`42::VARIANT`	`VARIANT`

Rules for Case Sensitivity

The keys of `MAP`s are case-sensitive, while keys of `UNION`s and `STRUCT`s are case-insensitive. For examples, see the Rules for Case Sensitivity section.

Updating Values of Nested Types

When performing *updates* on values of nested types, DuckDB performs a *delete* operation followed by an *insert* operation. When used in a table with ART indexes (either via explicit indexes or primary keys/unique constraints), this can lead to unexpected constraint violations.

Nesting

ARRAY, LIST, MAP, STRUCT and UNION types can be arbitrarily nested to any depth, so long as the type rules are observed.

Struct with LISTs:

```
SELECT {'birds': ['duck', 'goose', 'heron'], 'aliens': NULL, 'amphibians': ['frog', 'toad']};
```

Struct with list of MAPs:

```
SELECT {'test': [MAP([1, 5], [42.1, 45]), MAP([1, 5], [42.1, 45])]};
```

A list of UNIONs:

```
SELECT [union_value(num := 2), union_value(str := 'ABC')::UNION(str VARCHAR, num INTEGER)];
```

Performance Implications

The choice of data types can have a strong effect on performance. Please consult the Performance Guide for details.

Array Type

An ARRAY column stores fixed-sized arrays. All fields in the column must have the same length and the same underlying type. Arrays are typically used to store arrays of numbers, but can contain any uniform data type, including ARRAY, LIST and STRUCT types.

Arrays can be used to store vectors such as word embeddings or image embeddings.

To store variable-length lists, use the LIST type. See the data types overview for a comparison between nested data types.

> The ARRAY type in PostgreSQL allows variable-length fields. DuckDB's ARRAY type is fixed-length.

Creating Arrays

Arrays can be created using the `array_value(expr, ...)` function.

Construct with the `array_value` function:

```
SELECT array_value(1, 2, 3);
```

You can always implicitly cast an array to a list (and use list functions, like `list_extract`, `[i]`):

```
SELECT array_value(1, 2, 3)[2];
```

You can cast from a list to an array (the dimensions have to match):

```
SELECT [3, 2, 1]::INTEGER[3];
```

Arrays can be nested:

```
SELECT array_value(array_value(1, 2), array_value(3, 4), array_value(5, 6));
```

Arrays can store structs:

```
SELECT array_value({'a': 1, 'b': 2}, {'a': 3, 'b': 4});
```

Defining an Array Field

Arrays can be created using the `<TYPE_NAME>[<LENGTH>]{:.language-sql .highlight}` syntax. For example, to create an array field for 3 integers, run:

```
CREATE TABLE array_table (id INTEGER, arr INTEGER[3]);
INSERT INTO array_table VALUES (10, [1, 2, 3]), (20, [4, 5, 6]);
```

Retrieving Values from Arrays

Retrieving one or more values from an array can be accomplished using brackets and slicing notation, or through list functions like `list_extract` and `array_extract`. Using the example in Defining an Array Field.

The following queries for extracting the first element of an array are equivalent:

```
SELECT id, arr[1] AS element FROM array_table;
SELECT id, list_extract(arr, 1) AS element FROM array_table;
SELECT id, array_extract(arr, 1) AS element FROM array_table;
```

id	element
10	1
20	4

Using the slicing notation returns a `LIST`:

```
SELECT id, arr[1:2] AS elements FROM array_table;
```

id	elements
10	[1, 2]
20	[4, 5]

Functions

All `LIST` functions work with the ARRAY type. Additionally, several ARRAY-native functions are also supported. See the ARRAY functions.

Examples

Create sample data:

```
CREATE TABLE x (i INTEGER, v FLOAT[3]);
CREATE TABLE y (i INTEGER, v FLOAT[3]);
INSERT INTO x VALUES (1, array_value(1.0::FLOAT, 2.0::FLOAT, 3.0::FLOAT));
INSERT INTO y VALUES (1, array_value(2.0::FLOAT, 3.0::FLOAT, 4.0::FLOAT));
```

Compute cross product:

```
SELECT array_cross_product(x.v, y.v)
FROM x, y
WHERE x.i = y.i;
```

Compute cosine similarity:

```sql
SELECT array_cosine_similarity(x.v, y.v)
FROM x, y
WHERE x.i = y.i;
```

Ordering

The ordering of ARRAY instances is defined using a lexicographical order. NULL values compare greater than all other values and are considered equal to each other.

Bitstring Type

Name	Aliases	Description
BITSTRING	BIT	Variable-length strings of 1s and 0s

Bitstrings are strings of 1s and 0s. The bit type data is of variable length. A bitstring value requires 1 byte for each group of 8 bits, plus a fixed amount to store some metadata.

By default bitstrings will not be padded with zeroes. Bitstrings can be very large, having the same size restrictions as BLOBs.

Creating a Bitstring

A string encoding a bitstring can be cast to a BITSTRING:

```sql
SELECT '101010'::BITSTRING AS b;
```

b
101010

Creating a BITSTRING with a predefined length is possible with the bitstring function. The resulting bitstring will be left-padded with zeroes.

```sql
SELECT bitstring('0101011', 12) AS b;
```

b
000000101011

Numeric values (integer and float values) can also be converted to a BITSTRING via casting. For example:

```sql
SELECT 123::BITSTRING AS b;
```

b
00000000000000000000000001111011

Functions

See Bitstring Functions.

Blob Type

Name	Aliases	Description
BLOB	BYTEA, BINARY, VARBINARY	Variable-length binary data

The blob (**B**inary **L**arge **OB**ject) type represents an arbitrary binary object stored in the database system. The blob type can contain any type of binary data with no restrictions. What the actual bytes represent is opaque to the database system.

Create a BLOB value with a single byte (170):

```
SELECT '\xAA'::BLOB;
```

Create a BLOB value with three bytes (170, 171, 172):

```
SELECT '\xAA\xAB\xAC'::BLOB;
```

Create a BLOB value with two bytes (65, 66):

```
SELECT 'AB'::BLOB;
```

Blobs are typically used to store non-textual objects that the database does not provide explicit support for, such as images. While blobs can hold objects up to 4 GB in size, typically it is not recommended to store very large objects within the database system. In many situations it is better to store the large file on the file system, and store the path to the file in the database system in a VARCHAR field.

Functions

See Blob Functions.

Boolean Type

Name	Aliases	Description
BOOLEAN	BOOL	Logical Boolean (`true` / `false`)

The BOOLEAN type represents a statement of truth (“true” or “false”). In SQL, the BOOLEAN field can also have a third state “unknown” which is represented by the SQL NULL value.

Select the three possible values of a BOOLEAN column:

```
SELECT true, false, NULL::BOOLEAN;
```

Boolean values can be explicitly created using the literals `true` and `false`. However, they are most often created as a result of comparisons or conjunctions. For example, the comparison `i > 10` results in a Boolean value. Boolean values can be used in the `WHERE` and `HAVING` clauses of a SQL statement to filter out tuples from the result. In this case, tuples for which the predicate evaluates to `true` will pass the filter, and tuples for which the predicate evaluates to `false` or `NULL` will be filtered out. Consider the following example:

Create a table with the values 5, 15 and `NULL`:

```
CREATE TABLE integers (i INTEGER);
INSERT INTO integers VALUES (5), (15), (NULL);
```

Select all entries where `i > 10`:

```
SELECT * FROM integers WHERE i > 10;
```

In this case 5 and `NULL` are filtered out (`5 > 10` is `false` and `NULL > 10` is `NULL`):

i
15

Conjunctions

The AND / OR conjunctions can be used to combine Boolean values.

Below is the truth table for the AND conjunction (i.e., `x AND y`).

X	X AND true	X AND false	X AND NULL
true	true	false	NULL
false	false	false	false
NULL	NULL	false	NULL

Below is the truth table for the OR conjunction (i.e., `x OR y`).

X	X OR true	X OR false	X OR NULL
true	true	true	true
false	true	false	NULL
NULL	true	NULL	NULL

Expressions

See Logical Operators and Comparison Operators.

Date Types

Name	Aliases	Description
DATE		Calendar date (year, month, day)

A date specifies a combination of year, month and day. DuckDB follows the SQL standard's lead by counting dates exclusively in the Gregorian calendar, even for years before that calendar was in use. Dates can be created using the `DATE` keyword, where the data must be formatted according to the ISO 8601 format (`YYYY-MM-DD`).

```
SELECT DATE '1992-09-20';
```

Special Values

There are also three special date values that can be used on input:

Input string	Description
epoch	1970-01-01 (Unix system day zero)
infinity	Later than all other dates
-infinity	Earlier than all other dates

The values `infinity` and `-infinity` are specially represented inside the system and will be displayed unchanged; but `epoch` is simply a notational shorthand that will be converted to the date value when read.

```
SELECT
    '-infinity'::DATE AS negative,
    'epoch'::DATE AS epoch,
    'infinity'::DATE AS positive;
```

negative	epoch	positive
-infinity	1970-01-01	infinity

Functions

See Date Functions.

Enum Data Type

Name	Description
ENUM	Dictionary representing all possible string values of a column

The enum type represents a dictionary data structure with all possible unique values of a column. For example, a column storing the days of the week can be an enum holding all possible days. Enums are particularly interesting for string columns with low cardinality (i.e., fewer distinct values). This is because the column only stores a numerical reference to the string in the enum dictionary, resulting in immense savings in disk storage and faster query performance.

Creating Enums

You can create an enum using hardcoded values:

```
CREATE TYPE mood AS ENUM ('sad', 'ok', 'happy');
-- This statement will fail since enums cannot hold NULL values:
-- CREATE TYPE mood AS ENUM ('sad', NULL);
-- This statement will fail since enum values must be unique:
-- CREATE TYPE mood AS ENUM ('sad', 'sad');
```

You can create enums in a specific schema:

```
CREATE SCHEMA my_schema;
CREATE TYPE my_schema.mood AS ENUM ('sad', 'ok', 'happy');
```

Anonymous enums can be created on the fly during casting:

```
SELECT 'clubs'::ENUM ('spades', 'hearts', 'diamonds', 'clubs');
```

You can also create an enum using a `SELECT` statement that returns a single column of VARCHARs. The set of values from the select statement will be deduplicated automatically, and `NULL` values will be ignored:

```
CREATE TYPE region AS ENUM (SELECT region FROM sales_data);
```

If you are importing data from a file, you can create an enum for a VARCHAR column before importing:

```
CREATE TYPE region AS ENUM (SELECT region FROM 'sales_data.csv');
CREATE TABLE sales_data (amount INTEGER, region region);
COPY sales_data FROM 'sales_data.csv';
```

Using Enums

Enum values are case-sensitive, so 'maltese' and 'Maltese' are considered different values:

```
CREATE TYPE breed AS ENUM ('maltese', 'Maltese');
-- Will return false
SELECT 'maltese'::breed = 'Maltese'::breed;
-- Will error
SELECT 'MALTESE'::breed;
```

After an enum has been created, it can be used anywhere a standard built-in type is used. For example, we can create a table with a column that references the enum.

```
CREATE TABLE person (
    name TEXT,
    current_mood mood
);
INSERT INTO person VALUES
    ('Pedro', 'happy'),
    ('Mark', NULL),
    ('Pagliacci', 'sad'),
    ('Mr. Mackey', 'ok');
```

The following query will fail since the mood type does not have a `quackity-quack` value.

```
INSERT INTO person VALUES ('Hannes', 'quackity-quack');
```

Enums vs. Strings

DuckDB enums are automatically cast to VARCHAR types whenever necessary. This characteristic allows for comparisons between different enums, or an enum and a VARCHAR column.

It also allows for an enum to be used in any VARCHAR function. For example:

```
SELECT current_mood, regexp_matches(current_mood, '.*a.*') AS contains_a FROM person;
```

current_mood	contains_a
happy	true
NULL	NULL
sad	true
ok	false

When comparing two different enum types, DuckDB will cast both to strings and perform a string comparison:

```
CREATE TYPE new_mood AS ENUM ('happy', 'anxious');
SELECT * FROM person
WHERE current_mood = 'happy'::new_mood;
-- Equivalent to `WHERE current_mood::VARCHAR = 'happy'::VARCHAR`
```

name	current_mood
Pedro	happy

When comparing an enum to a VARCHAR, DuckDB will cast the enum to VARCHAR and perform a string comparison:

```
SELECT * FROM person
WHERE current_mood = name;
-- Equivalent to `WHERE current_mood::VARCHAR = name`
-- No rows returned
```

When comparing against a constant string, DuckDB will perform an optimization and `try_cast(<constant string>, enum_type){:.language-sql .highlight}` so that physically we are doing an integer comparison instead of a string comparison (but logically it is still a string comparison):

```
SELECT * FROM person
WHERE current_mood = 'sad';
-- Equivalent to `WHERE current_mood::VARCHAR = 'sad'`
```

name	current_mood
Pagliacci	sad

> **Warning.** This means that comparing against a random (non-equivalent) string always results in `false` (and does not error):

```
SELECT * FROM person
WHERE current_mood = 'bogus';
-- Equivalent to `WHERE current_mood::VARCHAR = 'bogus'`
-- No rows returned
```

If you want to enforce type-safety, cast to the enum explicitly:

```
SELECT * FROM person
WHERE current_mood = 'bogus'::mood;
-- Conversion Error: Could not convert string 'bogus' to UINT8
```

Ordering of Enums

Enum values are ordered according to their order in the enum's definition. For example:

```
CREATE TYPE priority AS ENUM ('low', 'medium', 'high');
SELECT 'low'::priority < 'high'::priority AS comp;
-- note that 'low'::VARCHAR < 'high'::VARCHAR is false!
```

comp
true

```
SELECT unnest(['medium'::priority, 'high'::priority, 'low'::priority]) AS m
ORDER BY m;
```

m
low
medium
high

> **Warning.** If you compare an enum to a non-enum (e.g., a VARCHAR or a different enum type), the enum will first be cast to a string (as described in the previous section), and the comparison will be done lexicographically as with strings:

```
CREATE TABLE tasks (name TEXT, priority_level priority);
INSERT INTO tasks VALUES ('a', 'low'), ('b', 'medium'), ('c', 'high');
-- WARNING!
-- Equivalent to `WHERE priority_level::VARCHAR >= 'medium'`
SELECT * FROM tasks
WHERE priority_level >= 'medium';
-- Misses the 'high' priority task!
```

name	priority_level
b	medium

So, if you want to e.g. "get all priorities at or above `medium`" then explicitly cast to the enum type:

```
SELECT * FROM tasks
WHERE priority_level >= 'medium'::priority;
```

name	priority_level
b	medium
c	high

Functions

See Enum Functions.

For example, show the available values in the `mood` enum using the `enum_range` function:

```
SELECT enum_range(NULL::mood) AS my_enum_range;
```

my_enum_range
[sad, ok, happy]

Enum Removal

Enum types are stored in the catalog, and a catalog dependency is added to each table that uses them. It is possible to drop an enum from the catalog using the following command:

```
DROP TYPE <enum_name>;
```

Currently, it is possible to drop enums that are used in tables without affecting the tables.

> **Warning.** This behavior of the enum removal feature is subject to change. In future releases, it is expected that any dependent columns must be removed before dropping the enum, or the enum must be dropped with the additional CASCADE parameter.

Geometry Data Type

Name	Description
GEOMETRY	Geospatial entity

The GEOMETRY data type is used to store and manipulate geometric objects, such as points, lines, and polygons.

The GEOMETRY type was part of the `spatial` extension but became a built-in data type in DuckDB v1.5. Most of the benefits of having GEOMETRY as a built-in type (e.g., storage optimizations, statistics, etc.) are therefore only available in databases using storage version v1.5 and above. However, almost all of the associated functions for working with geometries (e.g., calculating distances, areas, intersections) are still part of `spatial`.

Types of Geometries

Conceptually, the GEOMETRY type follows the core data model defined in the Simple Features standard, which is widely used in geospatial databases and GIS software. A GEOMETRY value can therefore represent 7 types of shapes:

Geometry Type	Description
Point	A single location in space, defined by its coordinates (e.g., longitude and latitude).
LineString	A sequence of points connected by straight lines, representing a path or route.
Polygon	A set of closed rings defined by a sequence of points, representing an area such as a country border or a building footprint. The first ring is the ”shell”, and ”interior” rings represent holes in the polygon.
MultiPoint	A collection of points.
MultiLineString	A collection of LineStrings.

Geometry Type	Description
MultiPolygon	A collection of Polygons.
GeometryCollection	A collection of different geometry types, allowing for complex geometries that combine points, lines, and polygons or even other nested geometry collections.

The textual representation of geometries uses "Well-Known Text" (WKT) format. Geometries can be cast to and from WKT strings, so you can use string literals to create geometries directly in SQL statements.

In the following example, we create a `GEOMETRY` column with the 7 different types of supported geometries:

```
CREATE TABLE geometries (
    id INTEGER,
    geom GEOMETRY
);

INSERT INTO geometries VALUES
  (1, 'POINT (30 10)'),
  (2, 'LINESTRING (30 10, 10 30, 40 40)'),
  (3, 'POLYGON ((30 10, 40 40, 20 40, 10 20, 30 10))'),
  (4, 'MULTIPOINT ((10 40), (40 30), (20 20), (30 10))'),
  (5, 'MULTILINESTRING ((10 10, 20 20, 10 40), (40 40, 30 30, 40 20))'),
  (6, 'MULTIPOLYGON (((30 20, 45 40, 10 40, 30 20)), ((15 5, 40 10, 10 20, 5 10,15 5)))'),
  (7, 'GEOMETRYCOLLECTION (POINT(40 10), LINESTRING(10 10,20 20,10 40), POLYGON((40 40,20 45,45 30,40
40)))');

SELECT * FROM geometries;
```

```
┌───────┬──────────────
```

The vertex dimensions of a GEOMETRY value must be consistent across all vertices. For example, if one vertex has X, Y, and Z coordinates, then all other vertices in that geometry must also have X, Y, and Z coordinates. This means that you cannot have a mix of 2D and 3D vertices within the same geometry. This also applies for collections of geometries, such as MULTIPOINT or GEOMETRYCOLLECTION, where all geometries within the collection must have the same vertex dimensions.

Functions that operate on GEOMETRY values typically ignore any additional dimensions beyond the X and Y unless explicitly specified, but they can still be stored and can be retrieved if needed.

In the following example, we create a GEOMETRY table with 2D, 3D(Z), 3D(M) and 4D(ZM) points:

```
CREATE TABLE points (
    id INTEGER,
    geom GEOMETRY
);

INSERT INTO points VALUES
  (1, 'POINT (30 10)'),
  (2, 'POINT Z (30 10 5)'),
  (3, 'POINT M (30 10 1)'),
  (4, 'POINT ZM (30 10 5 1)');

SELECT * FROM points;
```

```
----
```

id int32	geom geometry
1	POINT (30 10)
2	POINT Z (30 10 5)
3	POINT M (30 10 1)
4	POINT ZM (30 10 5 1)

```
-- But we cannot mix different vertex dimensions within the same geometry!
INSERT INTO points VALUES
  (5, 'MULTIPOINT (POINT (30 10), POINT Z (30 10 5))');
```

```
----
Invalid Input Error:
Geometry has inconsistent Z/M dimension
```

Empty Geometries

Geometries can also be ”empty” (e.g., POINT EMPTY, LINESTRING EMPTY, MULTIPOLYGON EMPTY, etc.) which means they don't contain any vertices. Empty geometries are still valid geometries and can be used in spatial operations, but they are mostly useful for representing the result of topological operations that don't have a valid geometrical representation (e.g., the intersection of two non-overlapping geometries is an empty geometry).

Geometry Storage

Internally GEOMETRY values are stored as a sequence of bytes, similarly to DuckDB's BLOB types. The exact binary format is not yet stabilized and may change in a future release, but as of DuckDB storage version v1.5 it is based on little-endian Well-Known Binary (WKB), which is a standard binary encoding for geometries. In older storage versions, geometries were stored in a different custom binary format used by the spatial extension, but this conversion is performed automatically at the storage layer and is not visible to the execution engine or the user.

Shredding and Compression

The `GEOMETRY` type supports a storage optimization called "shredding", which improves compression for geometry columns where all values share the same geometry type and vertex dimensions.

When a row group qualifies, DuckDB splits the geometry segment within the row group into primitive `STRUCT`, `LIST`, and `DOUBLE` segments that can be compressed independently using lightweight algorithms - far more efficiently than storing variable-size binary blobs.

The shredded layout depends on the geometry type:

- `POINT` - STRUCT(X DOUBLE, Y DOUBLE) (and/or Z, M)
- `LINESTRING` - STRUCT(X DOUBLE, Y DOUBLE)[]
- `POLYGON` - STRUCT(X DOUBLE, Y DOUBLE)[][]
- `MULTIPOINT`, `MULTILINESTRING`, `MULTIPOLYGON` - same as above, with one additional level of list nesting

Row groups are not shredded if they contain `GEOMETRYCOLLECTION`s, any `EMPTY` geometries, or multiple geometry sub-types.

Additionally, row groups are not shredded if they fall below the minimum size threshold (default: ~25% of the maximum row group size, i.e., 30,000 rows).

This threshold is configurable via the `geometry_minimum_shredding_size` setting. Set it to `0` to always shred, or `-1` to disable shredding entirely.

```
-- Disable shredding for geometry columns
SET geometry_minimum_shredding_size = -1;

-- Always shred geometry columns regardless of row group size
SET geometry_minimum_shredding_size = 0;
```

The primary benefit of shredding is significantly improved compression, but in the future we plan to add ways to expose the shredded representation directly to the execution engine without having to "reassemble" the geometry back into binary again.

The following example illustrates the effects of shredding on the storage footprint of a `GEOMETRY` column.

```
-- Attach a persistent database with storage version v1.5
ATTACH 'geometry_db.db' as geometry_db (STORAGE_VERSION 'v1.5.0');

USE geometry_db;

-- Disable shredding completely and create a table with 1 million 2D points
SET geometry_minimum_shredding_size = -1;

CREATE OR REPLACE TABLE points AS SELECT printf('POINT (%d %d)', x, y)::GEOMETRY AS geom
FROM range(0, 1000) AS rx(x), range(0, 1000) AS ry(y);

-- Checkpoint the database to persist the data and storage layout to disk
CHECKPOINT;

-- Attach a second database
ATTACH 'shredded_db.db' as shredded_db (STORAGE_VERSION 'v1.5.0');

USE shredded_db;

-- This time, set the minimum shredding size to 0 to always shred geometry columns,
-- and create the same table with 1 million 2D points
SET geometry_minimum_shredding_size = 0;

CREATE OR REPLACE TABLE points AS SELECT printf('POINT (%d %d)', x, y)::GEOMETRY AS geom
FROM range(0, 1000) AS rx(x), range(0, 1000) AS ry(y);

-- Checkpoint to persist the data and storage layout to disk, and apply shredding
CHECKPOINT;
```

```
-- Now check the storage layout and memory usage of the geometry column in both attached databases
SELECT database_name, database_size FROM pragma_database_size();
```

```
┌──────────────┬──────────────┐
│ database_name │ database_size │
│    varchar    │    varchar    │
├──────────────┼──────────────┤
│ shredded_db   │ 2.2 MiB      │
│ geometry_db   │ 6.5 MiB      │
│ memory        │ 0 bytes      │
└──────────────┴──────────────┘
```

```
-- Almost 3x smaller storage thanks to shredding!

-- We can inspect what type of segments are used to store the geometry column
-- in each database using the `pragma_storage_info` function.

-- The geometry column in `geometry_db` is stored as regular GEOMETRY segments
SELECT DISTINCT(segment_type) FROM pragma_storage_info('geometry_db.points');
```

```
┌──────────────┐
│ segment_type │
│   varchar    │
├──────────────┤
│ GEOMETRY     │
│ VALIDITY     │
└──────────────┘
```

```
-- While the geometry column in `shredded_db` is decomposed into primitive DOUBLE segments,
-- which can be compressed much more efficiently!
SELECT DISTINCT(segment_type) FROM pragma_storage_info('shredded_db.points');
```

```
┌──────────────┐
│ segment_type │
│   varchar    │
├──────────────┤
│ VALIDITY     │
│ DOUBLE       │
└──────────────┘
```

Geometry Statistics

GEOMETRY columns contain geometry-specific statistics that track the bounding box of the geometries in each row group, as well as the set of geometry types and vertex dimensions that are present within the row group.

You can inspect the statistics of a column using the `stats()` function:

```
CREATE TABLE geometries as select 'POINT Z (30 10 5)'::GEOMETRY as geom;

SELECT stats(geom) AS geom_stats FROM geometries;
```

```
┌──────────────
```

```
│  false, Has No Empty Part: true]][Has Null: false, Has No Null: true][Approx Unique: 1]
│
└──────────────────────────────────────────────────────────────────────────────────────────
```

These statistics can be used by the query optimizer to skip row groups that don't match the geometry type or vertex dimensions required by a query, or to speed up spatial predicates by first checking if the bounding box of the geometries in the row group overlaps with the bounding box of the query geometry.

Currently, only the && operator, which is used to check if the bounding box of a geometry intersects the bounding box of another geometry, can take advantage of geometry statistics when used in a `WHERE` clause. There is ongoing work to add support for more statistics-based optimizations to the functions in the `spatial` extension, such as `ST_Intersects`, `ST_Distance`, etc.

Persisting geometry statistics is only possible in storage versions v1.5 and above, and so if you are using an older storage version, the geometry statistics will turn into "unknown" statistics when checkpointing. In other words, the bounding box will be set to an infinitely large bounding box and all geometry types and vertex dimensions will be marked as maybe present, which means that the execution engine will not be able to do any optimizations based on the geometry statistics.

Coordinate Reference Systems

As far as the execution engine is concerned, geometries are considered to exist in a Cartesian coordinate system. In practice, however, most geospatial data is associated with a specific **Coordinate Reference System** (CRS) that defines how the coordinates relate to real-world locations on the Earth's surface.

A helpful analogy is to think of CRSs as the equivalent of "time zones", but for geospatial data. Just like how time zones define how local time relates to a standard reference time (e.g., UTC), CRSs define how the coordinates of a geometry relate to a standard reference system (e.g., WGS 84). CRSs are usually either geographic (e.g., WGS 84, which uses latitude and longitude) or projected (e.g., UTM, which uses linear units like meters).

When working with geospatial data, it's important to be aware of the CRS associated with different datasets. Performing spatial operations on geometries in different CRSs without proper transformation will most likely lead to incorrect results.

How are Coordinate Reference Systems Stored in DuckDB?

To avoid these kinds of mistakes, DuckDB makes it possible to explicitly associate a CRS with a `GEOMETRY` column.

This is done by passing a CRS "identifier" as a parameter of the `GEOMETRY` type. For example, a column of type `GEOMETRY('OGC:CRS84')` stores geometries that are associated with the "OGC CRS84" coordinate reference system.

CRS identifiers in DuckDB are always strings. `OGC:CRS84` is the identifier for a common geographic coordinate system spanning the whole globe where the X coordinate represents longitude and the Y coordinate represents latitude. DuckDB only knows this because the identifier 'OGC:CRS84' is registered as a *known* CRS in the system catalog.

By default, only a handful of common CRSs are registered as known, but extensions can also register additional known CRSs. In particular, the `spatial` extension registers over 7000 CRSs from the EPSG Geodetic Parameter Dataset, which is arguably the most widely used database of coordinate reference systems.

You can list all available CRSs known to DuckDB using the `duckdb_coordinate_systems()` function:

```
SELECT * FROM duckdb_coordinate_systems();
```

```
┌───────────────┬───────────────┬─────────────┬─────────────┬──────────┬──────────┬──────────┬──────────┬──────────┬──────────┐
│ database_name │ database_oid  │ schema_name │ schema_oid  │ crs_oid  │ crs_name │ auth_name │ auth_code │  projjson  │ wkt2_2019 │

```

```
┌─────────┬─────────┬─────────┬─────────┬──────────┬─────────┬─────────┬──────────┬──────────┬──────────┐
│ system  │    0    │ main    │    0    │   1353   │ OGC:CRS84 │ OGC   │ CRS84    │ {"$schema":"https://proj.org/schemas… │ GEOGCRS["WGS 84 (CRS84)",ENSEMBLE["W… │
└─────────┴─────────┴─────────┴─────────┴──────────┴─────────┴─────────┴──────────┴──────────┴──────────┘
```

Handling Unknown Coordinate Reference Systems

As mentioned above, only coordinate systems that are registered in the system catalog (and therefore "known" to DuckDB) can be used when creating GEOMETRY columns. If you try to create a GEOMETRY column with an unknown CRS identifier, either manually or by importing an external geospatial dataset, the statement will fail with an error.

```
SELECT 'POINT(1 2)'::GEOMETRY('DUCK:1337') AS my_point;
----
Binder Error:
Encountered unrecognized coordinate system 'DUCK:1337' when trying to create GEOMETRY type
The coordinate system definition may be incomplete or invalid ...
```

This restriction exists because DuckDB needs the complete CRS definition, not just an identifier, to perform coordinate transformations and to export to formats that embed CRS metadata, such as GeoParquet. Without a system catalog entry, there is no way to resolve an identifier to its full definition.

You can set the `ignore_unknown_crs` configuration option to `true` to simply skip any unknown CRSs and create GEOMETRY columns without CRS instead.

```
-- Ignore any unknown CRS identifiers
SET ignore_unknown_crs = true;

select 'POINT(1 2)'::GEOMETRY('DUCK:1337') AS my_point;
----
┌──────────────┐
│   my_point   │
│   geometry   │
├──────────────┤
│ POINT (1 2)  │
└──────────────┘
```

-- The geometry is created, but the CRS is dropped from the type!

Alternatively, if you are trying to define a GEOMETRY column yourself, you can provide a complete CRS definition in WKT or PROJJSON format instead of a shorthand identifier as the CRS parameter. However, as complete CRS definitions are usually very large, this gets unwieldy very quickly and is not recommended for interactive use.

It is currently not possible to define a custom CRS from within SQL, or to persist custom CRS definitions in a database such that DuckDB can use them to resolve CRS identifiers for geometry columns, but this is something we are considering for the future.

Working with Geometries in Different Coordinate Reference Systems

One benefit of tracking CRSs as part of the type system is that it prevents a lot of common mistakes that can occur when working with geometries from different coordinate systems. Most spatial functions that operate on multiple GEOMETRY values verify that all input expressions have the same CRS before performing the operation. Similarly, GEOMETRY columns can only be implicitly cast to and from other GEOMETRY columns if the source or the target don't have a CRS specified.

To convert a geometry from one CRS to another, you can use the `ST_Transform(geom, crs)` function from the `spatial` extension.

```
LOAD spatial;

SELECT ST_Transform('POINT(4.897070 52.377956)'::GEOMETRY('OGC:CRS84'), 'EPSG:3857') AS transformed;
----
┌──────────────────────────────────────────┐
│                transformed               │
```

```
┌──────────────────────────────────────────────┐
│            geometry('epsg:3857')             │
├──────────────────────────────────────────────┤
│ POINT (545139.3387790163 6868755.38408516)   │
└──────────────────────────────────────────────┘
```

You can also use the `ST_SetCRS(geom, crs)` function to assign a CRS to a geometry that doesn't have one, or to reassign a CRS without transforming coordinates (e.g., when the data is already in the correct coordinate system but lacks the correct CRS).

```
SELECT ST_SetCRS('POINT(4.897070 52.377956)'::GEOMETRY, 'OGC:CRS84') AS with_crs;
```

```
┌──────────────────────────────┐
│           with_crs           │
│ geometry('ogc:crs84')        │
├──────────────────────────────┤
│ POINT (4.89707 52.377956)    │
└──────────────────────────────┘
```

Or if you want to remove the CRS from a geometry, you can either just cast to `GEOMETRY`, or set the CRS to `''`:

```
SELECT 'POINT(4.897070 52.377956)'::GEOMETRY('OGC:CRS84')::GEOMETRY AS no_crs;
```

```
┌──────────────────────────────┐
│            no_crs            │
│           geometry           │
├──────────────────────────────┤
│ POINT (4.89707 52.377956)    │
└──────────────────────────────┘
```

```
SELECT ST_SetCRS('POINT(4.897070 52.377956)'::GEOMETRY('OGC:CRS84'), '') AS no_crs;
```

```
┌──────────────────────────────┐
│            no_crs            │
│           geometry           │
├──────────────────────────────┤
│ POINT (4.89707 52.377956)    │
└──────────────────────────────┘
```

You can of course also use `ST_CRS(geom)` to retrieve the CRS of a geometry:

```
SELECT ST_CRS('POINT(4.897070 52.377956)'::GEOMETRY('OGC:CRS84')) AS crs;
```

```
┌──────────┐
│   crs    │
│ varchar  │
├──────────┤
│ OGC:CRS84 │
└──────────┘
```

Functions

- See geometry functions for the list of built-in geometry functions.
- See the documentation of the `spatial` extension for the large set of additional geometry functions provided by the extension, including functions for calculating areas, distances, intersections, unions, and much more.

Interval Type

`INTERVAL`s represent periods of time that can be added to or subtracted from `DATE`, `TIMESTAMP`, `TIMESTAMPTZ`, or `TIME` values.

Name	Description
INTERVAL	Period of time

An INTERVAL can be constructed by providing amounts together with units. Units that aren't *months*, *days*, or *microseconds* are converted to equivalent amounts in the next smaller of these three basis units.

```
SELECT
    INTERVAL 1 YEAR, -- single unit using YEAR keyword; stored as 12 months
    INTERVAL (random() * 10) YEAR, -- parentheses necessary for variable amounts;
                                   -- stored as integer number of months
    INTERVAL '1 month 1 day', -- string type necessary for multiple units; stored as (1 month, 1 day)
    '16 months'::INTERVAL, -- string cast supported; stored as 16 months
    '48:00:00'::INTERVAL, -- HH::MM::SS string supported; stored as (48 * 60 * 60 * 1e6 microseconds)
;
```

> **Warning.** Decimal values are truncated to integers when used with unit keywords (unless the unit is SECONDS or MILLISECONDS).
>
> ```
> SELECT INTERVAL '1.5' YEARS;
> -- Returns 12 months; equivalent to `to_years(CAST(trunc(1.5) AS INTEGER))`
> ```
>
> For more precision, include the unit in the string or use a more granular unit; e.g., INTERVAL '1.5 years' or INTERVAL 18 MONTHS.

Three independent basis units are necessary because a month does not correspond to a fixed amount of days (February has fewer days than March) and a day doesn't correspond to a fixed amount of microseconds (days can be 25 hours or 23 hours long because of daylight saving time). The division into components makes the INTERVAL class suitable for adding or subtracting specific time units to a date. For example, we can generate a table with the first day of every month using the following SQL query:

```
SELECT DATE '2000-01-01' + INTERVAL (i) MONTH
FROM range(12) t(i);
```

When INTERVALs are deconstructed via the datepart function, the *months* component is additionally split into years and months, and the *microseconds* component is split into hours, minutes and microseconds. The *days* component is not split into additional units. To demonstrate this, the following query generates an INTERVAL called period by summing random amounts of the three basis units. It then extracts the aforementioned six parts from period, adds them back together, and confirms that the result is always equal to the original period.

```
SELECT
    period = list_reduce(
        [INTERVAL (datepart(part, period) || part) FOR part IN
             ['year', 'month', 'day', 'hour', 'minute', 'microsecond']
        ],
        (i1, i2) -> i1 + i2
    ) -- always true
FROM (
    VALUES (
        INTERVAL (random() * 123_456_789_123) MICROSECONDS
        + INTERVAL (random() * 12_345) DAYS
        + INTERVAL (random() * 12_345) MONTHS
    )
) _(period);
```

> **Warning.** The *microseconds* component is split only into hours, minutes and microseconds, rather than hours, minutes, *seconds* and microseconds.

The following table describes how these parts are extracted by datepart in formulas, as a function of the three basis units.

Part	Formula
year	#months // 12
month	#months % 12
day	#days
hour	#microseconds // (60 * 60 * 1_000_000)
minute	(#microseconds // (60 * 1_000_000)) % 60
microsecond	#microseconds % (60 * 1_000_000)

Additionally, `datepart` may be used to extract centuries, decades, quarters, seconds and milliseconds from `INTERVAL`s. However, these parts are not required when reassembling the original `INTERVAL`. In fact, if the previous query additionally extracted any of these additional parts, then the sum of the extracted parts would generally be larger than the original `period`.

Part	Formula
century	datepart('year', interval) // 100
decade	datepart('year', interval) // 10
quarter	datepart('month', interval) // 3 + 1
second	datepart('microsecond', interval) // 1_000_000
millisecond	datepart('microsecond', interval) // 1_000

> All units use 0-based indexing, except for quarters, which use 1-based indexing.

For example:

```
SELECT
    datepart('decade', INTERVAL 12 YEARS), -- returns 1
    datepart('year', INTERVAL 12 YEARS), -- returns 12
    datepart('second', INTERVAL 1_234 MILLISECONDS), -- returns 1
    datepart('microsecond', INTERVAL 1_234 MILLISECONDS), -- returns 1_234_000
;
```

Arithmetic with Timestamps, Dates and Intervals

`INTERVAL`s can be added to and subtracted from `TIMESTAMP`s, `TIMESTAMPTZ`s, `DATE`s, and `TIME`s using the + and − operators.

```
SELECT
    DATE '2000-01-01' + INTERVAL 1 YEAR,
    TIMESTAMP '2000-01-01 01:33:30' - INTERVAL '1 month 13 hours',
    TIME '02:00:00' - INTERVAL '3 days 23 hours', -- wraps; equals TIME '03:00:00'
;
```

> Adding an `INTERVAL` to a `DATE` returns a `TIMESTAMP` even when the `INTERVAL` has no microseconds component. The result is the same as if the `DATE` was cast to a `TIMESTAMP` (which sets the time component to `00:00:00`) before adding the `INTERVAL`.

Conversely, subtracting two `TIMESTAMP`s or two `TIMESTAMPTZ`s from one another creates an `INTERVAL` describing the difference between the timestamps with only the *days and microseconds* components. For example:

```
SELECT
    TIMESTAMP '2000-02-06 12:00:00' - TIMESTAMP '2000-01-01 11:00:00', -- 36 days 1 hour
    TIMESTAMP '2000-02-01' + (TIMESTAMP '2000-02-01' - TIMESTAMP '2000-01-01'), -- '2000-03-03', NOT
    '2000-03-01'
;
```

Subtracting two DATEs from one another does not create an INTERVAL but rather returns the number of days between the given dates as integer value.

> **Warning.** Extracting a part of the INTERVAL difference between two TIMESTAMPs is not equivalent to computing the number of partition boundaries between the two TIMESTAMPs for the corresponding unit, as computed by the datediff function:

```
SELECT
    datediff('day', TIMESTAMP '2020-01-01 01:00:00', TIMESTAMP '2020-01-02 00:00:00'), -- 1
    datepart('day', TIMESTAMP '2020-01-02 00:00:00' - TIMESTAMP '2020-01-01 01:00:00'), -- 0
;
```

Equality and Comparison

For equality and ordering comparisons only, the total number of microseconds in an INTERVAL is computed by converting the days basis unit to `24 * 60 * 60 * 1e6` microseconds and the months basis unit to 30 days, or `30 * 24 * 60 * 60 * 1e6` microseconds.

As a result, INTERVALs can compare equal even when they are functionally different, and the ordering of INTERVALs is not always preserved when they are added to dates or timestamps.

For example:

- `INTERVAL 30 DAYS = INTERVAL 1 MONTH`
- but `DATE '2020-01-01' + INTERVAL 30 DAYS != DATE '2020-01-01' + INTERVAL 1 MONTH`.

and

- `INTERVAL '30 days 12 hours' > INTERVAL 1 MONTH`
- but `DATE '2020-01-01' + INTERVAL '30 days 12 hours' < DATE '2020-01-01' + INTERVAL 1 MONTH`.

Functions

See the Date Part Functions page for a list of available date parts for use with an INTERVAL.

See the Interval Operators page for functions that operate on intervals.

List Type

A LIST column encodes lists of values. Fields in the column can have values with different lengths, but they must all have the same underlying type. LISTs are typically used to store arrays of numbers, but can contain any uniform data type, including other LISTs and STRUCTs.

LISTs are similar to PostgreSQL's ARRAY type. DuckDB uses the LIST terminology, but some `array_` functions are provided for PostgreSQL compatibility.

See the data types overview for a comparison between nested data types.

> For storing fixed-length lists, DuckDB uses the ARRAY type.

Creating Lists

Lists can be created using the `list_value(expr, ...)` function or the equivalent bracket notation `[expr, ...]`. The expressions can be constants or arbitrary expressions. To create a list from a table column, use the `list` aggregate function.

List of integers:

```
SELECT [1, 2, 3];
```

List of strings with a NULL value:

```
SELECT ['duck', 'goose', NULL, 'heron'];
```

List of lists with NULL values:

```
SELECT [['duck', 'goose', 'heron'], NULL, ['frog', 'toad'], []];
```

Create a list with the list_value function:

```
SELECT list_value(1, 2, 3);
```

Create a table with an INTEGER list column and a VARCHAR list column:

```
CREATE TABLE list_table (int_list INTEGER[], varchar_list VARCHAR[]);
```

Retrieving from Lists

Retrieving one or more values from a list can be accomplished using brackets and slicing notation, or through list functions like `list_extract`. Multiple equivalent functions are provided as aliases for compatibility with systems that refer to lists as arrays. For example, the function `array_slice`.

Example	Result
SELECT ['a', 'b', 'c'][3]	'c'
SELECT ['a', 'b', 'c'][-1]	'c'
SELECT ['a', 'b', 'c'][2 + 1]	'c'
SELECT list_extract(['a', 'b', 'c'], 3)	'c'
SELECT ['a', 'b', 'c'][1:2]	['a', 'b']
SELECT ['a', 'b', 'c'][:2]	['a', 'b']
SELECT ['a', 'b', 'c'][-2:]	['b', 'c']
SELECT list_slice(['a', 'b', 'c'], 2, 3)	['b', 'c']

Comparison and Ordering

The `LIST` type can be compared using all the comparison operators. These comparisons can be used in logical expressions such as `WHERE` and `HAVING` clauses, and return BOOLEAN values.

The `LIST` ordering is defined positionally using the following rules, where `min_len = min(len(l1), len(l2))`.

- **Equality.** `l1` and `l2` are equal, if for each `i` in `[1, min_len]`: `l1[i] = l2[i]`.
- **Less Than**. For the first index `i` in `[1, min_len]` where `l1[i] != l2[i]`: If `l1[i] < l2[i]`, `l1` is less than `l2`.

`NULL` values are compared following PostgreSQL's semantics. Lower nesting levels are used for tie-breaking.

Here are some queries returning `true` for the comparison.

```
SELECT [1, 2] < [1, 3] AS result;
```

```
SELECT [[1], [2, 4, 5]] < [[2]] AS result;
```

```
SELECT [ ] < [1] AS result;
```

These queries return `false`.

```
SELECT [ ] < [ ] AS result;
```

```sql
SELECT [1, 2] < [1] AS result;
```

These queries return NULL.

```sql
SELECT [1, 2] < [1, NULL, 4] AS result;
```

Functions

See List Functions.

Literal Types

DuckDB has special literal types for representing NULL, integer and string literals in queries. These have their own binding and conversion rules.

> Prior to DuckDB version 0.10.0, integer and string literals behaved identically to the INTEGER and VARCHAR types.

Null Literals

The NULL literal is denoted with the keyword NULL. The NULL literal can be implicitly converted to any other type.

Integer Literals

Integer literals are denoted as a sequence of one or more decimal digits. At runtime, these result in values of the INTEGER_LITERAL type. INTEGER_LITERAL types can be implicitly converted to any integer type in which the value fits. For example, the integer literal 42 can be implicitly converted to a TINYINT, but the integer literal 1000 cannot be.

> DuckDB does not support hexadecimal or binary literals directly. However, strings or string literals in hexadecimal or binary notation with 0x or 0b prefixes respectively, can be cast to integer types, e.g., '0xFF'::INT = 255 or 0b101::INT = 5.

Other Numeric Literals

Non-integer numeric literals can be denoted with decimal notation, using the period character (.) to separate the integer part and the decimal part of the number. Either the integer part or the decimal part may be omitted:

```sql
SELECT 1.5;          -- 1.5
SELECT .50;          -- 0.5
SELECT 2.;           -- 2.0
```

Non-integer numeric literals can also be denoted using *E notation*. In E notation, an integer or decimal literal is followed by an exponential part, which is denoted by e or E, followed by a literal integer indicating the exponent. The exponential part indicates that the preceding value should be multiplied by 10 raised to the power of the exponent:

```sql
SELECT 1e2;           -- 100
SELECT 6.02214e23;    -- Avogadro's constant
SELECT 1e-10;         -- 1 ångström
```

Underscores in Numeric Literals

DuckDB's SQL dialect allows using the underscore character _ in numeric literals as an optional separator. The rules for using underscores are as follows:

- Underscores are allowed in integer, decimal, hexadecimal and binary notation.

- Underscores cannot be the first or last character in a literal.
- Underscores have to have an integer/numeric part on either side of them, i.e., there cannot be multiple underscores in a row and underscores cannot appear immediately before or after a decimal or exponent.

Examples:

```
SELECT 100_000_000;          -- 100000000
SELECT '0xFF_FF'::INTEGER;   -- 65535
SELECT 1_2.1_2E0_1;          -- 121.2
SELECT '0b0_1_0_1'::INTEGER; -- 5
```

String Literals

String literals are delimited using single quotes (', apostrophe) and result in `STRING_LITERAL` values. Note that double quotes (") cannot be used as string delimiter character: instead, double quotes are used to delimit quoted identifiers.

Implicit String Literal Concatenation

Consecutive single-quoted string literals separated only by whitespace that contains at least one newline are implicitly concatenated:

```
SELECT 'Hello'
    ' '
    'World' AS greeting;
```

is equivalent to:

```
SELECT 'Hello'
    || ' '
    || 'World' AS greeting;
```

They both return the following result:

greeting
Hello World

Note that implicit concatenation only works if there is at least one newline between the literals. Using adjacent string literals separated by whitespace without a newline results in a syntax error:

```
SELECT 'Hello' ' ' 'World' AS greeting;
```

```
Parser Error:
syntax error at or near "' '"

LINE 1: SELECT 'Hello' ' ' 'World' AS greeting;
                       ^
```

Also note that implicit concatenation only works with single-quoted string literals, and does not work with other kinds of string values.

Implicit String Conversion

`STRING_LITERAL` instances can be implicitly converted to *any* other type.

For example, we can compare string literals with dates:

```
SELECT d > '1992-01-01' AS result
FROM (VALUES (DATE '1992-01-01')) t(d);
```

result
false

However, we cannot compare VARCHAR values with dates.

```
SELECT d > '1992-01-01'::VARCHAR
FROM (VALUES (DATE '1992-01-01')) t(d);
```

```
Binder Error:
Cannot compare values of type DATE and type VARCHAR - an explicit cast is required
```

Escape String Literals

To escape a single quote (apostrophe) character in a string literal, use `''`. For example, `SELECT '''' AS s` returns `'`.

To enable some common escape sequences, such as `\n` for the newline character, prefix a string literal with `e` (or `E`).

```
SELECT e'Hello\nworld' AS msg;
```

msg varchar
Hello\nworld

The following backslash escape sequences are supported:

Escape sequence	Name	ASCII code
`\b`	backspace	8
`\f`	form feed	12
`\n`	newline	10
`\r`	carriage return	13
`\t`	tab	9

Dollar-Quoted String Literals

DuckDB supports dollar-quoted string literals, which are surrounded by double-dollar symbols (`$$`):

```
SELECT $$Hello
world$$ AS msg;
```

msg varchar
Hello\nworld

```
SELECT $$The price is $9.95$$ AS msg;
```

msg
The price is $9.95

Even more, you can insert alphanumeric tags in the double-dollar symbols to allow for the use of regular double-dollar symbols *within* the string literal:

```
SELECT $tag$ this string can contain newlines,
'single quotes',
"double quotes",
and $$dollar quotes$$ $tag$ AS msg;
```

msg
varchar
this string can contain newlines,\n'single quotes',\n"double quotes",\nand $$dollar quotes$$

Implicit concatenation only works for single-quoted string literals, not with dollar-quoted ones.

Map Type

MAPs are similar to STRUCTs in that they are an ordered list of key-value pairs. However, MAPs do not need to have the same keys present for each row, and thus are suitable for use cases where the schema is unknown beforehand or varies per row.

MAPs must have a single type for all keys, and a single type for all values. Keys and values can be any type, and the type of the keys does not need to match the type of the values (e.g., a MAP of VARCHAR to INT is valid). MAPs may not have duplicate keys. MAPs return NULL if a key is not found rather than throwing an error as structs do.

In contrast, STRUCTs must have string keys, but each value may have a different type. See the data types overview for a comparison between nested data types.

To construct a MAP, use the bracket syntax preceded by the MAP keyword.

Creating Maps

A map with VARCHAR keys and INTEGER values. This returns `{key1=10, key2=20, key3=30}`:

```
SELECT MAP {'key1': 10, 'key2': 20, 'key3': 30};
```

Alternatively use the `map_from_entries` function. This returns `{key1=10, key2=20, key3=30}`:

```
SELECT map_from_entries([('key1', 10), ('key2', 20), ('key3', 30)]);
```

A map can be also created using two lists: keys and values. This returns `{key1=10, key2=20, key3=30}`:

```
SELECT MAP(['key1', 'key2', 'key3'], [10, 20, 30]);
```

A map can also use INTEGER keys and NUMERIC values. This returns `{1=42.001, 5=-32.100}`:

```
SELECT MAP {1: 42.001, 5: -32.1};
```

Keys and/or values can also be nested types. This returns `{[a, b]=[1.1, 2.2], [c, d]=[3.3, 4.4]}`:

```
SELECT MAP {['a', 'b']: [1.1, 2.2], ['c', 'd']: [3.3, 4.4]};
```

Create a table with a map column that has INTEGER keys and DOUBLE values:

```
CREATE TABLE tbl (col MAP(INTEGER, DOUBLE));
```

Retrieving from Maps

MAP values can be retrieved using the `map_extract_value` function or bracket notation:

```
SELECT MAP {'key1': 5, 'key2': 43}['key1'];
```

```
5
```

If the key has the wrong type, an error is thrown. If it has the correct type but is merely not contained in the map, a `NULL` value is returned:

```
SELECT MAP {'key1': 5, 'key2': 43}['key3'];
```

```
NULL
```

The `map_extract` function (and its synonym `element_at`) can be used to retrieve a value wrapped in a list; it returns an empty list if the key is not contained in the map:

```
SELECT map_extract(MAP {'key1': 5, 'key2': 43}, 'key1');
```

```
[5]
```

```
SELECT MAP {'key1': 5, 'key2': 43}['key3'];
```

```
[]
```

Comparison Operators

Nested types can be compared using all the comparison operators. These comparisons can be used in logical expressions for both `WHERE` and `HAVING` clauses, as well as for creating Boolean values.

The ordering is defined positionally in the same way that words can be ordered in a dictionary. `NULL` values compare greater than all other values and are considered equal to each other.

At the top level, `NULL` nested values obey standard SQL `NULL` comparison rules: comparing a `NULL` nested value to a non-`NULL` nested value produces a `NULL` result. Comparing nested value *members*, however, uses the internal nested value rules for `NULL`s, and a `NULL` nested value member will compare above a non-`NULL` nested value member.

Functions

See Map Functions.

NULL Values

`NULL` values are special values that are used to represent missing data in SQL. Columns of any type can contain `NULL` values. Logically, a `NULL` value can be seen as "the value of this field is unknown".

A `NULL` value can be inserted to any field that does not have the `NOT NULL` qualifier:

```
CREATE TABLE integers (i INTEGER);
INSERT INTO integers VALUES (NULL);
```

`NULL` values have special semantics in many parts of the query as well as in many functions:

> Any comparison with a `NULL` value returns `NULL`, including `NULL = NULL`.

You can use `IS NOT DISTINCT FROM` to perform an equality comparison where `NULL` values compare equal to each other. Use `IS (NOT) NULL` to check if a value is `NULL`.

```
SELECT NULL = NULL;
```

```
NULL
```

```
SELECT NULL IS NOT DISTINCT FROM NULL;
```

```
true
```

```
SELECT NULL IS NULL;
```

```
true
```

NULL and Functions

A function that has an input argument as `NULL` **usually** returns `NULL`.

```
SELECT cos(NULL);
```

```
NULL
```

The `coalesce` function is an exception to this: it takes any number of arguments, and returns for each row the first argument that is not `NULL`. If all arguments are `NULL`, `coalesce` also returns `NULL`.

```
SELECT coalesce(NULL, NULL, 1);
```

```
1
```

```
SELECT coalesce(10, 20);
```

```
10
```

```
SELECT coalesce(NULL, NULL);
```

```
NULL
```

The `ifnull` function is a two-argument version of `coalesce`.

```
SELECT ifnull(NULL, 'default_string');
```

```
default_string
```

```
SELECT ifnull(1, 'default_string');
```

```
1
```

NULL and AND / OR

`NULL` values have special behavior when used with AND and OR. For details, see the Boolean Type documentation.

NULL and IN / NOT IN

The behavior of `... IN <something with a NULL>`{:.language-sql .highlight} is different from `... IN <something with no NULLs>`{:.language-sql .highlight}. For details, see the `IN` documentation.

NULL and Aggregate Functions

`NULL` values are ignored in most aggregate functions.

Aggregate functions that do not ignore `NULL` values include: `first`, `last`, `list` and `array_agg`. To exclude `NULL` values from those aggregate functions, the `FILTER` clause can be used.

```
CREATE TABLE integers (i INTEGER);
INSERT INTO integers VALUES (1), (10), (NULL);
```

```
SELECT min(i) FROM integers;
```

```
1
```

```
SELECT max(i) FROM integers;
```

```
10
```

Numeric Types

Fixed-Width Integer Types

The types `TINYINT`, `SMALLINT`, `INTEGER`, `BIGINT` and `HUGEINT` store whole numbers, that is, numbers without fractional components, of various ranges. Attempts to store values outside of the allowed range will result in an error. The types `UTINYINT`, `USMALLINT`, `UINTEGER`, `UBIGINT` and `UHUGEINT` store whole unsigned numbers. Attempts to store negative numbers or values outside of the allowed range will result in an error.

Name	Aliases	Min	Max	Size in bytes
`TINYINT`	`INT1`	-2^7	2^7 - 1	1
`SMALLINT`	`INT2`, `INT16`, `SHORT`	-2^15	2^15 - 1	2
`INTEGER`	`INT4`, `INT32`, `INT`, `SIGNED`	-2^31	2^31 - 1	4
`BIGINT`	`INT8`, `INT64`, `LONG`	-2^63	2^63 - 1	8
`HUGEINT`	`INT128`	-2^127	2^127 - 1	16
`UTINYINT`	`UINT8`	0	2^8 - 1	1
`USMALLINT`	`UINT16`	0	2^16 - 1	2
`UINTEGER`	`UINT32`	0	2^32 - 1	4
`UBIGINT`	`UINT64`	0	2^64 - 1	8
`UHUGEINT`	`UINT128`	0	2^128 - 1	16

> `INT8` is a 64-bit integer, and is not the signed equivalent of `UINT8`, an unsigned, 8-bit integer. The type aliases `INT1`, `INT2`, `INT4` and `INT8` for signed integers were inherited from PostgreSQL, where digits in these names indicate their size in *bytes*, whereas the type aliases for their unsigned equivalents, `UINT8`, `UINT16`, `UINT32` and `UINT64`, indicate their size in *bits* following the C/C++ convention.

The type integer is the common choice, as it offers the best balance between range, storage size, and performance. The `SMALLINT` type is generally only used if disk space is at a premium. The `BIGINT` and `HUGEINT` types are designed to be used when the range of the integer type is insufficient.

Variable-Length Integers

The previously mentioned integer types all have in common that the numbers in the minimum and maximum range all have the same storage size, `UTINYINT` is 1 byte, `SMALLINT` is 2 bytes, etc. But sometimes you need numbers that are even bigger than what is supported by a `HUGEINT`! In these situations, you can use the `BIGNUM` type, which stores positive numbers in a similar fashion as other integer types, but uses three additional bytes to store the required size and a sign bit. A number with N decimal digits requires approximately `0.415 * N + 3` bytes when stored in a `BIGNUM`.

Unlike variable-length integer implementations in other systems, there are limits to `BIGNUM`: the maximal and minimal representable values are approximately `±4.27e20201778`. Those are numbers with 20,201,779 decimal digits and storing a single such number requires 8 megabytes.

Fixed-Point Decimals

The data type `DECIMAL(WIDTH, SCALE)` (also available under the alias `NUMERIC(WIDTH, SCALE)`) represents an exact fixed-point decimal value. When creating a value of type `DECIMAL`, the `WIDTH` and `SCALE` can be specified to define which size of decimal values can be held in the field. The `WIDTH` field determines how many digits can be held, and the `scale` determines the number of digits after the decimal point. For example, the type `DECIMAL(3, 2)` can fit the value `1.23`, but cannot fit the value `12.3` or the value `1.234`. The default `WIDTH` and `SCALE` is `DECIMAL(18, 3)`, if none are specified.

Addition, subtraction and multiplication of two fixed-point decimals returns another fixed-point decimal with the required `WIDTH` and `SCALE` to contain the exact result, or throws an error if the required `WIDTH` would exceed the maximal supported `WIDTH`, which is currently 38.

Division of fixed-point decimals does not typically produce numbers with finite decimal expansion. Therefore, DuckDB uses approximate floating-point arithmetic for all divisions that involve fixed-point decimals and accordingly returns floating-point data types.

Internally, decimals are represented as integers depending on their specified `WIDTH`.

Width	Internal	Size (bytes)
1-4	`INT16`	2
5-9	`INT32`	4
10-18	`INT64`	8
19-38	`INT128`	16

Performance can be impacted by using too large decimals when not required. In particular, decimal values with a width above 19 are slow, as arithmetic involving the `INT128` type is much more expensive than operations involving the `INT32` or `INT64` types. It is therefore recommended to stick with a `WIDTH` of `18` or below, unless there is a good reason for why this is insufficient.

Floating-Point Types

The data types `FLOAT` and `DOUBLE` precision are variable-precision numeric types. In practice, these types are usually implementations of IEEE Standard 754 for Binary Floating-Point Arithmetic (single and double precision, respectively), to the extent that the underlying processor, operating system, and compiler support it.

Name	Aliases	Description
`FLOAT`	`FLOAT4`, `REAL`	Single precision floating-point number (4 bytes)
`DOUBLE`	`FLOAT8`	Double precision floating-point number (8 bytes)

Like for fixed-point data types, conversion from literals or casts from other datatypes to floating-point types stores inputs that cannot be represented exactly as approximations. However, it can be harder to predict what inputs are affected by this. For example, it is not surprising that `1.3::DECIMAL(1, 0) - 0.7::DECIMAL(1, 0) != 0.6::DECIMAL(1, 0)` but it may be surprising that `1.3::FLOAT - 0.7::FLOAT != 0.6::FLOAT`.

Additionally, whereas multiplication, addition and subtraction of fixed-point decimal data types is exact, these operations are only approximate on floating-point binary data types.

For more complex mathematical operations, however, floating-point arithmetic is used internally and more precise results can be obtained if intermediate steps are *not* cast to fixed point formats of the same width as in- and outputs. For example, `(10::FLOAT / 3::FLOAT)::FLOAT * 3 = 10` whereas `(10::DECIMAL(18, 3) / 3::DECIMAL(18, 3))::DECIMAL(18, 3) * 3 = 9.999`.

In general:

- If you require exact storage of numbers with a known number of decimal digits and require exact additions, subtractions and multiplications (such as for monetary amounts), use the `DECIMAL` data type or its `NUMERIC` alias instead.
- If you want to do fast or complicated calculations, the floating-point data types may be more appropriate. However, if you use the results for anything important, you should evaluate your implementation carefully for corner cases (ranges, infinities, underflows, invalid operations) that may be handled differently from what you expect and you should familiarize yourself with common floating-point pitfalls. The article "What Every Computer Scientist Should Know About Floating-Point Arithmetic" by David Goldberg and the floating point series on Bruce Dawson's blog provide excellent starting points.

On most platforms, the `FLOAT` type has a range of at least 1E-37 to 1E+37 with a precision of at least 6 decimal digits. The `DOUBLE` type typically has a range of around 1E-307 to 1E+308 with a precision of at least 15 digits. Positive numbers outside of these ranges (and negative numbers outside the mirrored ranges) may cause errors on some platforms but will usually be converted to zero or infinity, respectively.

In addition to ordinary numeric values, the floating-point types have several special values representing IEEE 754 special values:

- `Infinity`: infinity
- `-Infinity`: negative infinity
- `NaN`: not a number

On machines with the required CPU/FPU support, DuckDB follows the IEEE 754 specification regarding these special values, with two exceptions:

- `NaN` compares equal to `NaN` and greater than any other floating point number.
- Some floating point functions, like `sqrt` / `sin` / `asin` throw errors rather than return `NaN` for values outside their ranges of definition.

To insert these values as literals in a SQL command, you must put quotes around them, you may abbreviate `Infinity` as `Inf`, and you may use any capitalization. For example:

```
SELECT
    sqrt(2) > '-inf',
    'nan' > sqrt(2);
```

(sqrt(2) > '-inf')	('nan' > sqrt(2))
true	true

Universally Unique Identifiers (UUIDs)

DuckDB supports universally unique identifiers (UUIDs) through the `UUID` type. These use 128 bits and are represented internally as `HUGEINT` values. When printed, they are shown with lowercase hexadecimal characters, separated by dashes as follows: `<12345678>-<1234>-<1234>-<1234>-<1234567890ab>{:.language-sql .highlight}` (using 36 characters in total including the dashes). For example, `4ac7a9e9-607c-4c8a-84f3-843f0191e3fd` is a valid UUID.

DuckDB supports generating UUIDv4 and UUIDv7 identifiers. To retrieve the version of a UUID value, use the `uuid_extract_version` function.

UUIDv4

To generate a UUIDv4 value, use the `uuid()` function or its aliases the `uuidv4()` and `gen_random_uuid()` functions.

UUIDv7

To generate a UUIDv7 value, use the `uuidv7()` function. To retrieve the timestamp from a UUIDv7 value, use the `uuid_extract_timestamp` function:

```
SELECT uuid_extract_timestamp(uuidv7()) AS ts;
```

ts
2025-04-19 15:51:20.07+00

Rounding

Casting from floating-point or fixed-point types to integers means that the source numbers are rounded.

The following default rounding logic applies:

- Casting from `FLOAT` and `DOUBLE` to integers of any size: round to the nearest integer, with ties (halfs) rounded to the nearest even number (banker's rounding).

```
SELECT 2.5::FLOAT::INTEGER AS result;  -- round to even
```

result
2

- Casting from `DECIMAL` to integers of any size: round to the nearest integer, with ties (halfs) rounded away from zero.

```
SELECT 2.5::DECIMAL::INTEGER AS result;  -- round away from zero
SELECT 2.5::INTEGER AS result;           -- number literals are treated as DECIMALs
```

result
3

If non-default rounding logic is required, functions like `ceil`, `floor`, `round` and `round_even` should be used.

Functions

See Numeric Functions and Operators.

Struct Data Type

Conceptually, a `STRUCT` column contains an ordered list of columns called "entries". The entries are referenced by name using strings. This document refers to those entry names as keys. Each row in the `STRUCT` column must have the same keys. The names of the struct entries are part of the *schema*. Each row in a `STRUCT` column must have the same layout. The names of the struct entries are case-insensitive.

`STRUCT`s are typically used to nest multiple columns into a single column, and the nested column can be of any type, including other `STRUCT`s and `LIST`s.

`STRUCT`s are similar to PostgreSQL's `ROW` type. The key difference is that DuckDB `STRUCT`s require the same keys in each row of a `STRUCT` column. This allows DuckDB to provide significantly improved performance by fully utilizing its vectorized execution engine, and also enforces type consistency for improved correctness. DuckDB includes a `row` function as a special way to produce a `STRUCT`, but does not have a `ROW` data type. See an example below and the STRUCT functions documentation for details.

See the data types overview for a comparison between nested data types.

Creating Structs

Structs can be created using the `struct_pack(name := expr, ...)` function, the equivalent array notation `{'name': expr, ...}`, using a row variable, or using the `row` function.

Create a struct using the `struct_pack` function. Note the lack of single quotes around the keys and the use of the `:=` operator:

```
SELECT struct_pack(key1 := 'value1', key2 := 42) AS s;
```

Create a struct using the array notation:

```
SELECT {'key1': 'value1', 'key2': 42} AS s;
```

Create a struct using a row variable:

```
SELECT d AS s FROM (SELECT 'value1' AS key1, 42 AS key2) d;
```

Create a struct of integers:

```
SELECT {'x': 1, 'y': 2, 'z': 3} AS s;
```

Create a struct of strings with a `NULL` value:

```
SELECT {'yes': 'duck', 'maybe': 'goose', 'huh': NULL, 'no': 'heron'} AS s;
```

Create a struct with a different type for each key:

```
SELECT {'key1': 'string', 'key2': 1, 'key3': 12.345} AS s;
```

Create a struct of structs with `NULL` values:

```
SELECT {
        'birds': {'yes': 'duck', 'maybe': 'goose', 'huh': NULL, 'no': 'heron'},
        'aliens': NULL,
        'amphibians': {'yes': 'frog', 'maybe': 'salamander', 'huh': 'dragon', 'no': 'toad'}
    } AS s;
```

Adding or Updating Fields of Structs

To add new fields or update existing ones, you can use `struct_update`:

```
SELECT struct_update({'a': 1, 'b': 2}, b := 3, c := 4) AS s;
```

Alternatively, `struct_insert` also allows adding new fields but not updating existing ones.

Retrieving from Structs

Retrieving a value from a struct can be accomplished using dot notation, bracket notation, or through struct functions like `struct_extract`.

Use dot notation to retrieve the value at a key's location. In the following query, the subquery generates a struct column `a`, which we then query with `a.x`.

```
SELECT a.x FROM (SELECT {'x': 1, 'y': 2, 'z': 3} AS a);
```

If a key contains a space, simply wrap it in double quotes (").

```
SELECT a."x space" FROM (SELECT {'x space': 1, 'y': 2, 'z': 3} AS a);
```

Bracket notation may also be used. Note that this uses single quotes (') since the goal is to specify a certain string key and only constant expressions may be used inside the brackets (no expressions):

```
SELECT a['x space'] FROM (SELECT {'x space': 1, 'y': 2, 'z': 3} AS a);
```

The `struct_extract` function is also equivalent. This returns 1:

```
SELECT struct_extract({'x space': 1, 'y': 2, 'z': 3}, 'x space');
```

`unnest` / `STRUCT.*`

Rather than retrieving a single key from a struct, the `unnest` special function can be used to retrieve all keys from a struct as separate columns. This is particularly useful when a prior operation creates a struct of unknown shape, or if a query must handle any potential struct keys:

```
SELECT unnest(a)
FROM (SELECT {'x': 1, 'y': 2, 'z': 3} AS a);
```

x	y	z
1	2	3

The same can be achieved with the star notation (`*`), which additionally allows modifications of the returned columns:

```
SELECT a.* EXCLUDE ('y')
FROM (SELECT {'x': 1, 'y': 2, 'z': 3} AS a);
```

x	z
1	3

> **Warning.** The star notation is currently limited to top-level struct columns and non-aggregate expressions.

Dot Notation Order of Operations

Referring to structs with dot notation can be ambiguous with referring to schemas and tables. In general, DuckDB looks for columns first, then for struct keys within columns. DuckDB resolves references in these orders, using the first match to occur:

No Dots

```
SELECT part1
FROM tbl;
```

1. `part1` is a column

One Dot

```
SELECT part1.part2
FROM tbl;
```

1. `part1` is a table, `part2` is a column
2. `part1` is a column, `part2` is a property of that column

Two (or More) Dots

```
SELECT part1.part2.part3
FROM tbl;
```

1. `part1` is a schema, `part2` is a table, `part3` is a column
2. `part1` is a table, `part2` is a column, `part3` is a property of that column
3. `part1` is a column, `part2` is a property of that column, `part3` is a property of that column

Any extra parts (e.g., `.part4.part5`, etc.) are always treated as properties

Creating Structs with the `row` Function

The `row` function can be used to automatically convert multiple columns to a single struct column. When using `row` the keys will be empty strings allowing for easy insertion into a table with a struct column. Columns, however, cannot be initialized with the `row` function, and must be explicitly named. For example, inserting values into a struct column using the `row` function:

```
CREATE TABLE t1 (s STRUCT(v VARCHAR, i INTEGER));
INSERT INTO t1 VALUES (row('a', 42));
SELECT * FROM t1;
```

The table will contain a single entry:

```
{'v': a, 'i': 42}
```

The following produces the same result as above:

```
CREATE TABLE t1 AS (
    SELECT row('a', 42)::STRUCT(v VARCHAR, i INTEGER)
);
```

Initializing a struct column with the `row` function will fail:

```
CREATE TABLE t2 AS SELECT row('a');
```

```
Invalid Input Error:
A table cannot be created from an unnamed struct
```

When casting between structs, the names of at least one field have to match. Therefore, the following query will fail:

```
SELECT a::STRUCT(y INTEGER) AS b
FROM
    (SELECT {'x': 42} AS a);
```

```
Binder Error:
STRUCT to STRUCT cast must have at least one matching member
```

A workaround for this is to use `struct_pack` instead:

```
SELECT struct_pack(y := a.x) AS b
FROM
    (SELECT {'x': 42} AS a);
```

The `row` function can be used to return unnamed structs. For example:

```
SELECT row(x, x + 1, y) FROM (SELECT 1 AS x, 'a' AS y) AS s;
```

This produces `(1, 2, a)`.

If using multiple expressions when creating a struct, the `row` function is optional. The following query returns the same result as the previous one:

```
SELECT (x, x + 1, y) AS s FROM (SELECT 1 AS x, 'a' AS y);
```

Comparison and Ordering

The `STRUCT` type can be compared using all the comparison operators. These comparisons can be used in logical expressions such as `WHERE` and `HAVING` clauses, and return `BOOLEAN` values.

Comparisons are done in lexicographical order, with individual entries being compared as usual except that `NULL` values are treated as larger than all other values.

Specifically:

- If all values of `s1` and `s2` compare equal, then `s1` and `s2` compare equal.

- else, if `s1.value[i] < s2.value[i] OR s2.value[i] is NULL` for the first index `i` where `s1.value[i] != s2.value[i]`, then `s1` is less than `s2`, and vice versa.

Structs of different types are implicitly cast to a struct type with the union of the involved keys, following the rules for combination casting.

The following queries return `true`:

```
SELECT {'k1': 0, 'k2': 0} < {'k1': 1, 'k2': 0};
```

```
SELECT {'k1': 'hello'} < {'k1': 'world'};
```

```
SELECT {'k1': 0, 'k2': 0} < {'k1': 0, 'k2': NULL};
```

```
SELECT {'k1': 0} < {'k2': 0};
```

```
SELECT  {'k1': 0, 'k2': 0} < {'k2': 0, 'k3': 0};
```

```
SELECT {'k1': 1, 'k2': 0} > {'k3': 0, 'k1': 0};
```

The following queries return `false`:

```
SELECT {'k1': 1, 'k2': 0} < {'k1': 0, 'k2': 1};
```

```
SELECT {'k1': [0]} < {'k1': [0, 0]};
```

```
SELECT {'k1': 1} > {'k2': 0};
```

```
SELECT {'k1': 0, 'k2': 0} < {'k3': 0, 'k1': 1};
```

```
SELECT  {'k1': 1, 'k2': 0} > {'k2': 0, 'k3': 0};
```

Updating the Schema

Starting with DuckDB v1.3.0, it's possible to update the sub-schema of structs using the `ALTER TABLE` clause.

To follow the examples, initialize the `test` table as follows:

```
CREATE TABLE test (s STRUCT(i INTEGER, j INTEGER));
INSERT INTO test VALUES (ROW(1, 1)), (ROW(2, 2));
```

Adding a Field

Add field `k INTEGER` to struct `s` in table `test`:

```
ALTER TABLE test ADD COLUMN s.k INTEGER;
FROM test;
```

```
┌──────────────────────────────────────────┐
│                    s                     │
│ struct(i integer, j integer, k integer)  │
├──────────────────────────────────────────┤
│ {'i': 1, 'j': 1, 'k': NULL}              │
│ {'i': 2, 'j': 2, 'k': NULL}              │
└──────────────────────────────────────────┘
```

Dropping a Field

Drop field `i` from struct `s` in table `test`:

```
ALTER TABLE test DROP COLUMN s.i;
FROM test;
```

```
┌──────────────────────────────┐
│              s               │
│ struct(j integer, k integer) │
├──────────────────────────────┤
│ {'j': 1, 'k': NULL}          │
│ {'j': 2, 'k': NULL}          │
└──────────────────────────────┘
```

Renaming a Field

Renaming field `j` of struct `s` to `v1` in table `test`:

```
ALTER TABLE test RENAME s.j TO v1;
FROM test;
```

```
┌──────────────────────────────┐
│              s               │
│ struct(v1 integer, k integer)│
├──────────────────────────────┤
│ {'v1': 1, 'k': NULL}         │
│ {'v1': 2, 'k': NULL}         │
└──────────────────────────────┘
```

Functions

See Struct Functions.

Text Types

In DuckDB, strings can be stored in the VARCHAR field. The field allows storage of Unicode characters. Internally, the data is encoded as UTF-8.

Name	Aliases	Description
VARCHAR	CHAR, BPCHAR, STRING, TEXT	Variable-length character string
VARCHAR(n)	CHAR(n), BPCHAR(n), STRING(n), TEXT(n)	Variable-length character string. The maximum length n has no effect and is only provided for compatibility

Specifying a Length Limit

Specifying the length for the VARCHAR, STRING and TEXT types is not required and has no effect on the system. Specifying the length will not improve performance or reduce storage space of the strings in the database. These variants are supported for compatibility with other systems that do require a length to be specified for strings.

If you wish to restrict the number of characters in a VARCHAR column for data integrity reasons the CHECK constraint should be used, for example:

```
CREATE TABLE strings (
    val VARCHAR CHECK (length(val) <= 10) -- val has a maximum length of 10
);
```

The VARCHAR field allows storage of Unicode characters. Internally, the data is encoded as UTF-8.

Specifying a Compression Type

You can specify a compression type for a string with the `USING COMPRESSION` clause. For example, to apply zstd compression, run:

```
CREATE TABLE tbl (s VARCHAR USING COMPRESSION zstd);
```

Text Type Values

Values of the text type are character strings, also known as string values or simply strings. At runtime, string values are constructed in one of the following ways:

- referencing columns whose declared or implied type is the text data type
- string literals
- casting expressions to a text type
- applying a string operator, or invoking a function that returns a text type value

Strings with Special Characters

To use special characters in a string, use escape string literals or dollar-quoted string literals. Alternatively, you can use concatenation and the `chr` character function:

```
SELECT 'Hello' || chr(10) || 'world' AS msg;
```

```
┌─────────────┐
│     msg     │
│   varchar   │
├─────────────┤
│ Hello\nworld │
└─────────────┘
```

Functions

See Text Functions and Pattern Matching.

Time Types

The `TIME` and `TIMETZ` types specify the hour, minute, second, microsecond of a day.

Name	Aliases	Description
`TIME`	`TIME WITHOUT TIME ZONE`	Time of day
`TIMETZ`	`TIME WITH TIME ZONE`	Time of day, with time zone offset
`TIME_NS`		Time of day, nanosecond precision

Instances can be created using the type names as a keyword, where the data must be formatted according to the ISO 8601 format (`hh:mm:ss[.zzzzzz[zzz]][+-TT[:tt]]`).

```
SELECT TIME '1992-09-20 11:30:00.123456';
```

```
11:30:00.123456
```

```
SELECT TIMETZ '1992-09-20 11:30:00.123456';
```

```
11:30:00.123456+00
```

```
SELECT TIMETZ '1992-09-20 11:30:00.123456-02:00';
```

```
13:30:00.123456+00
```

```
SELECT TIMETZ '1992-09-20 11:30:00.123456+05:30';
```

```
06:00:00.123456+00
```

```
SELECT '15:30:00.123456789'::TIME_NS;
```

```
15:30:00.123456789
```

`TIME_NS` values can also be read from Parquet when the type is `TIME` with unit `NANOS`.

> **Warning.** The `TIME` type should only be used in rare cases, where the date part of the timestamp can be disregarded. Most applications should use the `TIMESTAMP` types to represent their timestamps.

Timestamp Types

Timestamps represent points in time. As such, they combine `DATE` and `TIME` information. They can be created using the type name followed by a string formatted according to the ISO 8601 format, `YYYY-MM-DD hh:mm:ss[.zzzzzzzzz][+-TT[:tt]]`, which is also the format we use in this documentation. Decimal places beyond the supported precision are ignored.

Timestamp Types

Name	Aliases	Description
`TIMESTAMP_NS`		Naive timestamp with nanosecond precision
`TIMESTAMP`	`DATETIME`, `TIMESTAMP WITHOUT TIME ZONE`	Naive timestamp with microsecond precision
`TIMESTAMP_MS`		Naive timestamp with millisecond precision
`TIMESTAMP_S`		Naive timestamp with second precision
`TIMESTAMPTZ`	`TIMESTAMP WITH TIME ZONE`	Time zone aware timestamp with microsecond precision

> **Warning.** Since there is not currently a `TIMESTAMP_NS WITH TIME ZONE` data type, external columns with nanosecond precision and `WITH TIME ZONE` semantics, e.g., Parquet timestamp columns with `isAdjustedToUTC=true`, are converted to `TIMESTAMP WITH TIME ZONE` and thus lose precision when read using DuckDB.

```
SELECT TIMESTAMP_NS '1992-09-20 11:30:00.123456789';
```

```
1992-09-20 11:30:00.123456789
```

```
SELECT TIMESTAMP '1992-09-20 11:30:00.123456789';
```

```
1992-09-20 11:30:00.123456
```

```
SELECT TIMESTAMP_MS '1992-09-20 11:30:00.123456789';
```

```
1992-09-20 11:30:00.123
```

```
SELECT TIMESTAMP_S '1992-09-20 11:30:00.123456789';
```

```
1992-09-20 11:30:00
```

```
SELECT TIMESTAMPTZ '1992-09-20 11:30:00.123456789';
```

```
1992-09-20 11:30:00.123456+00
```

```
SELECT TIMESTAMPTZ '1992-09-20 12:30:00.123456789+01:00';
```

```
1992-09-20 11:30:00.123456+00
```

DuckDB distinguishes timestamps `WITHOUT TIME ZONE` and `WITH TIME ZONE` (of which the only current representative is `TIMESTAMP WITH TIME ZONE`).

Despite the name, a `TIMESTAMP WITH TIME ZONE` does not store time zone information. Instead, it only stores the `INT64` number of non-leap microseconds since the Unix epoch `1970-01-01 00:00:00+00`, and thus unambiguously identifies a point in absolute time, or *instant*. The reason for the labels *time zone aware* and `WITH TIME ZONE` is that timestamp arithmetic, *binning*, and string formatting for this type are performed in a configured time zone, which defaults to the system time zone and is just `UTC+00:00` in the examples above.

The corresponding `TIMESTAMP WITHOUT TIME ZONE` stores the same `INT64`, but arithmetic, binning and string formatting follow the straightforward rules of Coordinated Universal Time (UTC) without offsets or time zones. Accordingly, `TIMESTAMP`s could be interpreted as UTC timestamps, but more commonly they are used to represent *local* observations of time recorded in an unspecified time zone, and operations on these types can be interpreted as simply manipulating tuple fields following nominal temporal logic. It is a common data cleaning problem to disambiguate such observations, which may also be stored in raw strings without time zone specification or UTC offsets, into unambiguous `TIMESTAMP WITH TIME ZONE` instants. One possible solution to this is to append UTC offsets to strings, followed by an explicit cast to `TIMESTAMP WITH TIME ZONE`. Alternatively, a `TIMESTAMP WITHOUT TIME ZONE` may be created first and then be combined with a time zone specification to obtain a time zone aware `TIMESTAMP WITH TIME ZONE`.

Conversion between Strings and Naïve / Time Zone-Aware Timestamps

The conversion between strings *without* UTC offsets or IANA time zone names and `WITHOUT TIME ZONE` types is unambiguous and straightforward. The conversion between strings *with* UTC offsets or time zone names and `WITH TIME ZONE` types is also unambiguous, but requires the `ICU` extension to handle time zone names.

When strings *without* UTC offsets or time zone names are converted to a `WITH TIME ZONE` type, the string is interpreted in the configured time zone. When strings with UTC offsets are passed to a `WITHOUT TIME ZONE` type, the offsets or time zone specifications are ignored. When strings with time zone names other than UTC are passed to a `WITHOUT TIME ZONE` type, an error is thrown.

Finally, when `WITH TIME ZONE` and `WITHOUT TIME ZONE` types are converted to each other via explicit or implicit casts, the translation uses the configured time zone. To use an alternative time zone, the `timezone` function provided by the `ICU` extension may be used:

```
SELECT
    timezone('America/Denver', TIMESTAMP '2001-02-16 20:38:40') AS aware1,
    timezone('America/Denver', TIMESTAMPTZ '2001-02-16 04:38:40') AS naive1,
    timezone('UTC', TIMESTAMP '2001-02-16 20:38:40+00:00') AS aware2,
    timezone('UTC', TIMESTAMPTZ '2001-02-16 04:38:40 Europe/Berlin') AS naive2;
```

aware1	naive1	aware2	naive2
2001-02-17 04:38:40+01	2001-02-15 20:38:40	2001-02-16 21:38:40+01	2001-02-16 03:38:40

Note that `TIMESTAMP`s are displayed without time zone specification in the results, following ISO 8601 rules for local times, while time-zone aware `TIMESTAMPTZ`s are displayed with the UTC offset of the configured time zone, which is `'Europe/Berlin'` in the example. The UTC offsets of `'America/Denver'` and `'Europe/Berlin'` at all involved instants are `-07:00` and `+01:00`, respectively.

Special Values

Three special strings can be used to create timestamps:

Input string	Description
`epoch`	1970-01-01 00:00:00[+00] (Unix system time zero)
`infinity`	Later than all other timestamps
`-infinity`	Earlier than all other timestamps

The values `infinity` and `-infinity` are special cased and are displayed unchanged, whereas the value `epoch` is simply a notational shorthand that is converted to the corresponding timestamp value when read.

```
SELECT '-infinity'::TIMESTAMP, 'epoch'::TIMESTAMP, 'infinity'::TIMESTAMP;
```

Negative	Epoch	Positive
-infinity	1970-01-01 00:00:00	infinity

Functions

See Timestamp Functions.

Time Zones

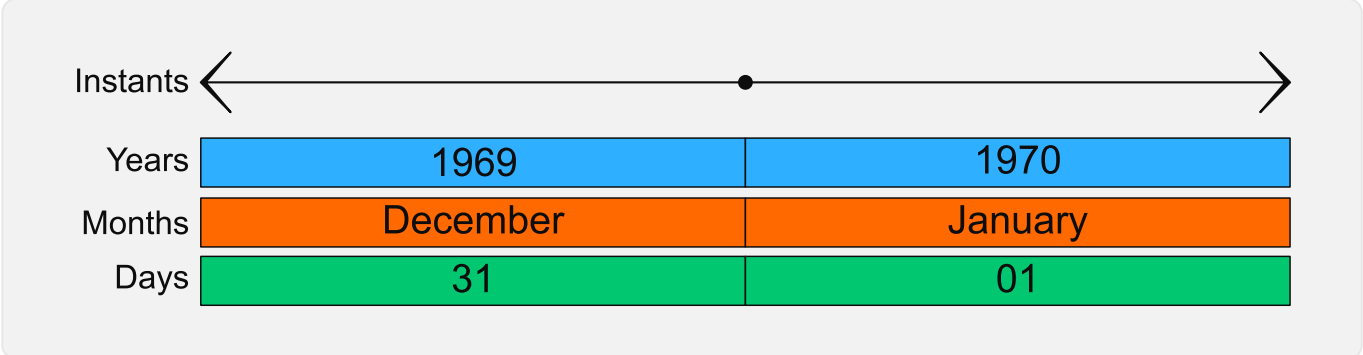
To understand time zones and the `WITH TIME ZONE` types, it helps to start with two concepts: *instants* and *temporal binning*.

Instants

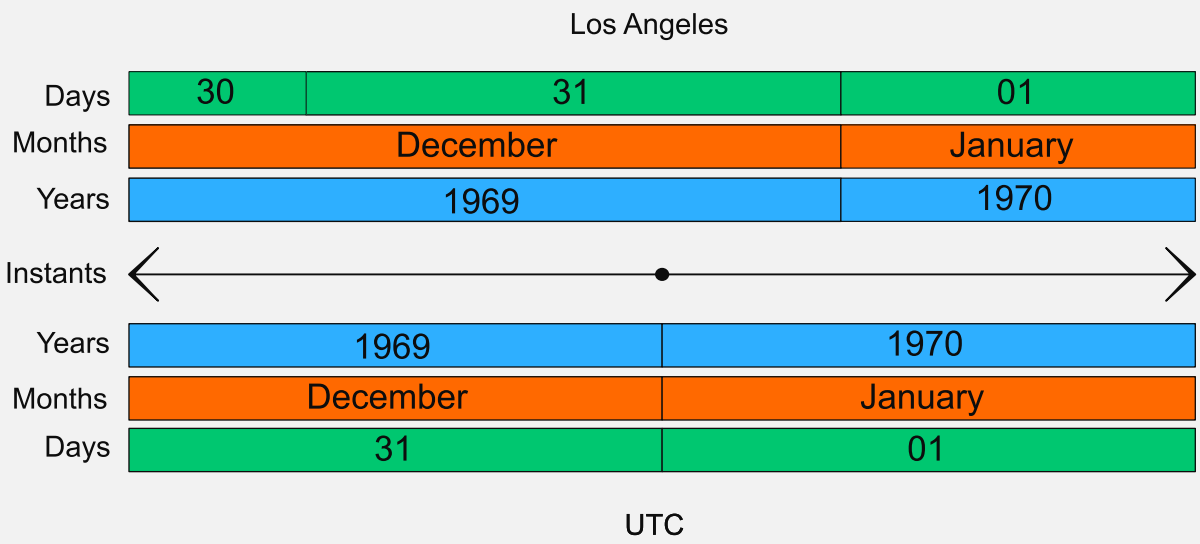
An instant is a point in absolute time, usually given as a count of some time increment from a fixed point in time (called the *epoch*). This is similar to how positions on the earth's surface are given using latitude and longitude relative to the equator and the Greenwich Meridian. In DuckDB, the fixed point is the Unix epoch `1970-01-01 00:00:00+00:00`, and the increment is in seconds, milliseconds, microseconds, or nanoseconds, depending on the specific data type.

Temporal Binning

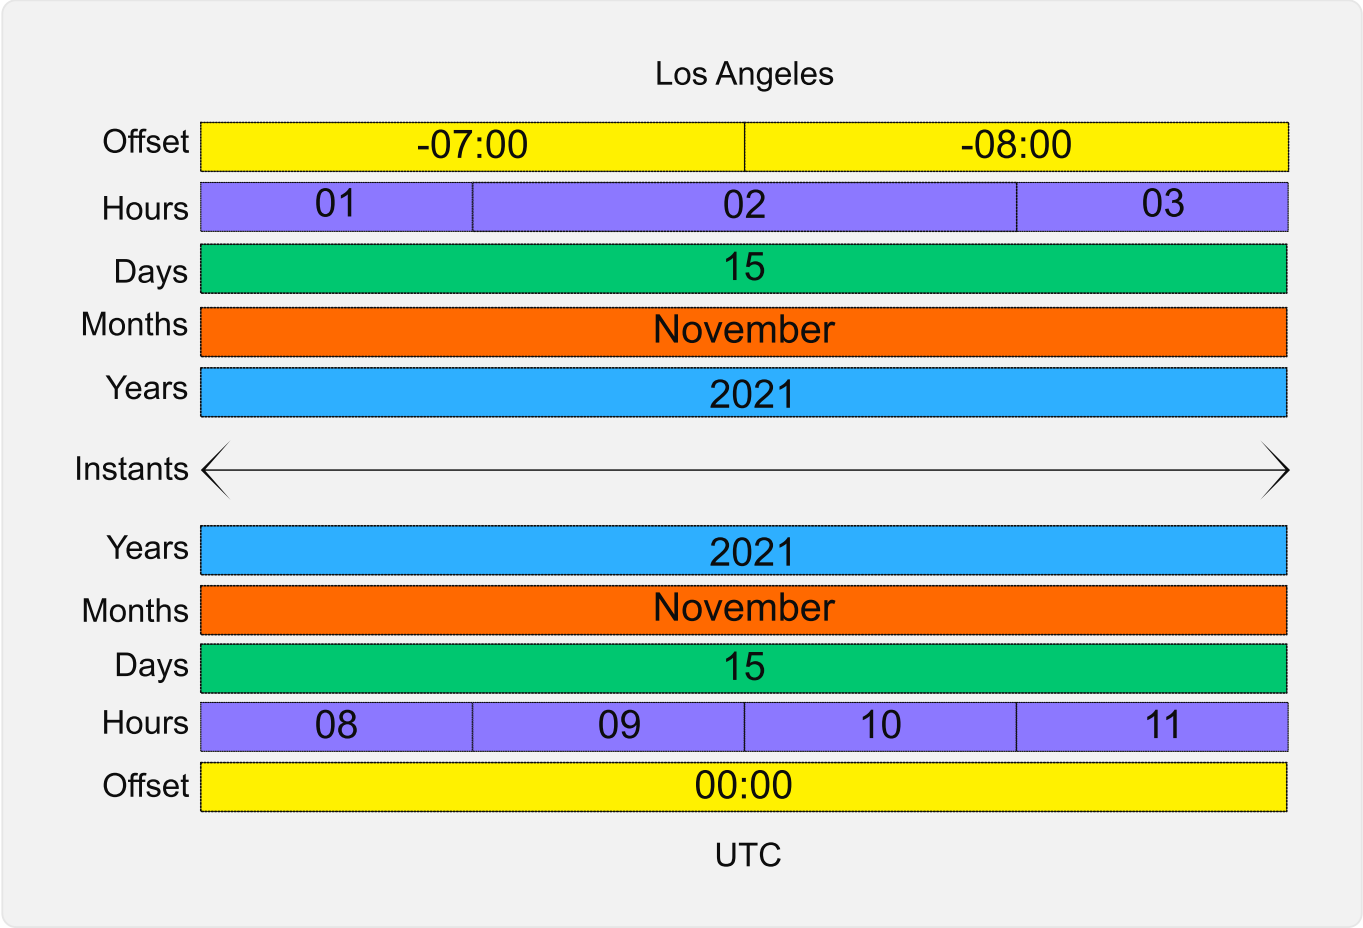
Binning is a common practice with continuous data: A range of possible values is broken up into contiguous subsets and the binning operation maps actual values to the *bin* they fall into. *Temporal binning* is simply applying this practice to instants; for example, by binning instants into years, months and days.



Temporal binning rules are complex, and generally come in two sets: *time zones* and *calendars*. For most tasks, the calendar will just be the widely used Gregorian calendar, but time zones apply locale-specific rules and can vary widely. For example, here is what binning for the `'America/Los_Angeles'` time zone looks like near the epoch:



The most common temporal binning problem occurs when daylight saving time changes. The example below contains a daylight saving time change where the ”hour” bin is two hours long. To distinguish the two hours, another range of bins containing the offset from UTC is needed:



Time Zone Support

The `TIMESTAMPTZ` type can be binned into calendar and clock bins using a suitable extension. The built-in ICU extension implements all the binning and arithmetic functions using the International Components for Unicode time zone and calendar functions.

To set the time zone to use, first load the ICU extension. The ICU extension comes pre-bundled with several DuckDB clients (including Python, R, JDBC and ODBC), so this step can be skipped in those cases. In other cases you might first need to install and load the ICU extension.

```
INSTALL icu;
LOAD icu;
```

Next, use the `SET TimeZone` command:

```
SET TimeZone = 'America/Los_Angeles';
```

Time binning operations for `TIMESTAMPTZ` will then be implemented using the given time zone.

A list of available time zones can be pulled from the `pg_timezone_names()` table function:

```
SELECT
    name,
    abbrev,
    utc_offset
FROM pg_timezone_names()
ORDER BY
    name;
```

You can also find a reference table of available time zones.

Calendar Support

The ICU extension also supports non-Gregorian calendars using the `SET Calendar` command. Note that the `INSTALL` and `LOAD` steps are only required if the DuckDB client does not bundle the ICU extension.

```
INSTALL icu;
LOAD icu;
SET Calendar = 'japanese';
```

Time binning operations for `TIMESTAMPTZ` will then be implemented using the given calendar. In this example, the `era` part will now report the Japanese imperial era number.

A list of available calendars can be pulled from the `icu_calendar_names()` table function:

```
SELECT name
FROM icu_calendar_names()
ORDER BY 1;
```

Settings

The current value of the `TimeZone` and `Calendar` settings are determined by ICU when it starts up. They can be queried from in the `duckdb_settings()` table function:

```
SELECT *
FROM duckdb_settings()
WHERE name = 'TimeZone';
```

name	value	description	input_type
TimeZone	Europe/Amsterdam	The current time zone	VARCHAR

```
SELECT *
FROM duckdb_settings()
WHERE name = 'Calendar';
```

name	value	description	input_type
Calendar	gregorian	The current calendar	VARCHAR

> If you find that your binning operations are not behaving as you expect, check the `TimeZone` and `Calendar` values and adjust them if needed.

Time Zone Reference List

An up-to-date version of this list can be pulled from the `pg_timezone_names()` table function:

```
SELECT name, abbrev
FROM pg_timezone_names()
ORDER BY name;
```

Union Type

A `UNION` *type* (not to be confused with the SQL `UNION` operator) is a nested type capable of holding one of multiple "alternative" values, much like the `union` in C. The main difference is that these `UNION` types are *tagged unions* and thus always carry a discriminator "tag" which signals which alternative it is currently holding, even if the inner value itself is null. `UNION` types are thus more similar to C++17's `std::variant`, Rust's `Enum` or the "sum type" present in most functional languages.

`UNION` types must always have at least one member, and while they can contain multiple members of the same type, the tag names must be unique. `UNION` types can have at most 256 members.

Under the hood, `UNION` types are implemented on top of `STRUCT` types, and simply keep the "tag" as the first entry.

`UNION` values can be created with the `union_value(tag := expr)` function or by casting from a member type.

Example

Create a table with a `UNION` column:

```
CREATE TABLE tbl1 (u UNION(num INTEGER, str VARCHAR));
INSERT INTO tbl1 VALUES (1), ('two'), (union_value(str := 'three'));
```

Any type can be implicitly cast to a `UNION` containing the type. Any `UNION` can also be implicitly cast to another `UNION` if the source `UNION` members are a subset of the target's (if the cast is unambiguous).

`UNION` uses the member types' `VARCHAR` cast functions when casting to `VARCHAR`:

```
SELECT u FROM tbl1;
```

u
1
two
three

Select all the `str` members:

```
SELECT union_extract(u, 'str') AS str
FROM tbl1;
```

str
NULL
two
three

Alternatively, you can use 'dot syntax' similarly to STRUCTs.

```
SELECT u.str
FROM tbl1;
```

str
NULL
two
three

Select the currently active tag from the UNION as an ENUM.

```
SELECT union_tag(u) AS t
FROM tbl1;
```

t
num
str
str

Union Casts

Compared to other nested types, UNIONs allow a set of implicit casts to facilitate unintrusive and natural usage when working with their members as "subtypes". However, these casts have been designed with two principles in mind, to avoid ambiguity and to avoid casts that could lead to loss of information. This prevents UNIONs from being completely "transparent", while still allowing UNION types to have a "supertype" relationship with their members.

Thus UNION types can't be implicitly cast to any of their member types in general, since the information in the other members not matching the target type would be "lost". If you want to coerce a UNION into one of its members, you should use the `union_extract` function explicitly instead.

The only exception to this is when casting a UNION to VARCHAR, in which case the members will all use their corresponding VARCHAR casts. Since everything can be cast to VARCHAR, this is "safe" in a sense.

Casting to Unions

A type can always be implicitly cast to a UNION if it can be implicitly cast to one of the UNION member types.

- If there are multiple candidates, the built in implicit casting priority rules determine the target type. For example, a `FLOAT → UNION(i INTEGER, v VARCHAR)` cast will always cast the FLOAT to the INTEGER member before VARCHAR.

- If the cast still is ambiguous, i.e., there are multiple candidates with the same implicit casting priority, an error is raised. This usually happens when the UNION contains multiple members of the same type, e.g., a FLOAT → UNION(i INTEGER, num INTEGER) is always ambiguous.

So how do we disambiguate if we want to create a UNION with multiple members of the same type? By using the union_value function, which takes a keyword argument specifying the tag. For example, union_value(num := 2::INTEGER) will create a UNION with a single member of type INTEGER with the tag num. This can then be used to disambiguate in an explicit (or implicit, read on below!) UNION to UNION cast, like CAST(union_value(b := 2) AS UNION(a INTEGER, b INTEGER)).

Casting between Unions

UNION types can be cast between each other if the source type is a "subset" of the target type. In other words, all the tags in the source UNION must be present in the target UNION, and all the types of the matching tags must be implicitly castable between source and target. In essence, this means that UNION types are covariant with respect to their members.

Ok	Source	Target	Comments
✅	UNION(a A, b B)	UNION(a A, b B, c C)	
✅	UNION(a A, b B)	UNION(a A, b C)	if B can be implicitly cast to C
❌	UNION(a A, b B, c C)	UNION(a A, b B)	
❌	UNION(a A, b B)	UNION(a A, b C)	if B can't be implicitly cast to C
❌	UNION(A, B, D)	UNION(A, B, C)	

Comparison and Sorting

Since UNION types are implemented on top of STRUCT types internally, they can be used with all the comparison operators as well as in both WHERE and HAVING clauses with the same semantics as STRUCTs. The "tag" is always stored as the first struct entry, which ensures that the UNION types are compared and ordered by "tag" first.

Functions

See Union Functions.

Typecasting

Typecasting is an operation that converts a value in one particular data type to the closest corresponding value in another data type. Like other SQL engines, DuckDB supports both implicit and explicit typecasting.

Explicit Casting

Explicit typecasting is performed by using a CAST expression. For example, CAST(col AS VARCHAR) or col::VARCHAR explicitly cast the column col to VARCHAR. See the cast page for more information.

Implicit Casting

In many situations, the system will add casts by itself. This is called *implicit* casting and happens, for example, when a function is called with an argument that does not match the type of the function but can be cast to the required type.

Implicit casts can only be added for a number of type combinations, and is generally only possible when the cast cannot fail. For example, an implicit cast can be added from `INTEGER` to `DOUBLE` – but not from `DOUBLE` to `INTEGER`.

Consider the function `sin(DOUBLE)`. This function takes as input argument a column of type `DOUBLE`, however, it can be called with an integer as well: `sin(1)`. The integer is converted into a double before being passed to the `sin` function.

> **Tip.** To check whether a type can be implicitly cast to another type, use the `can_cast_implicitly` function.

Combination Casting

When values of different types need to be combined to an unspecified joint parent type, the system will perform implicit casts to an automatically selected parent type. For example, `list_value(1::INT64, 1::UINT64)` creates a list of type `INT128[]`. The implicit casts performed in this situation are sometimes more lenient than regular implicit casts. For example, a `BOOL` value may be cast to `INT` (with `true` mapping to `1` and `false` to `0`) even though this is not possible for regular implicit casts.

This *combination casting* occurs for comparisons (= / < / >), set operations (`UNION` / `EXCEPT` / `INTERSECT`), and nested type constructors (`list_value` / `[...]` / `MAP`).

Casting Operations Matrix

Values of a particular data type cannot always be cast to any arbitrary target data type. The only exception is the `NULL` value – which can always be converted between types. The following matrix describes which conversions are supported. When implicit casting is allowed, it implies that explicit casting is also possible.

Legend:
✗ casting is not allowed
● implicit casting
■ explicit casting

Even though a casting operation is supported based on the source and target data type, it does not necessarily mean the cast operation will succeed at runtime.

> **Deprecated.** Prior to version 0.10.0, DuckDB allowed any type to be implicitly cast to VARCHAR during function binding. Version 0.10.0 introduced a breaking change which no longer allows implicit casts to VARCHAR. The `old_implicit_casting` configuration option setting can be used to revert to the old behavior. However, please note that this flag will be deprecated in the future.

Lossy Casts

Casting operations that result in loss of precision are allowed. For example, it is possible to explicitly cast a numeric type with fractional digits – such as `DECIMAL`, `FLOAT` or `DOUBLE` – to an integral type like `INTEGER` or `BIGINT`. The number will be rounded.

```
SELECT CAST(3.1 AS INTEGER);  -- 3
SELECT CAST(3.5 AS INTEGER);  -- 4
SELECT CAST(-1.7 AS INTEGER); -- -2
```

The applicable rounding rules can be found on the `NUMERIC type page`.

Overflows

Casting operations that would result in a value overflow throw an error. For example, the value `999` is too large to be represented by the `TINYINT` data type. Therefore, an attempt to cast that value to that type results in a runtime error:

```
SELECT CAST(999 AS TINYINT);
```

```
Conversion Error:
Type INT32 with value 999 can't be cast because the value is out of range for the destination type INT8
```

So even though the cast operation from `INTEGER` to `TINYINT` is supported, it is not possible for this particular value. `TRY_CAST` can be used to convert the value into `NULL` instead of throwing an error.

Varchar

The `VARCHAR` type acts as a universal target: any arbitrary value of any arbitrary type can always be cast to the VARCHAR type. This type is also used for displaying values in the shell.

```
SELECT CAST(42.5 AS VARCHAR);
```

Casting from VARCHAR to another data type is supported, but can raise an error at runtime if DuckDB cannot parse and convert the provided text to the target data type.

```
SELECT CAST('NotANumber' AS INTEGER);
```

In general, casting to VARCHAR is a lossless operation and any type can be cast back to the original type after being converted into text.

```
SELECT CAST(CAST([1, 2, 3] AS VARCHAR) AS INTEGER[]);
```

Literal Types

Integer literals (such as `42`) and string literals (such as `'string'`) have special implicit casting rules. See the `literal types page` for more information.

Lists / Arrays

Lists can be explicitly cast to other lists using the same casting rules. The cast is applied to the children of the list. For example, if we convert an `INTEGER[]` list to a `VARCHAR[]` list, the child `INTEGER` elements are individually cast to VARCHAR and a new list is constructed.

```
SELECT CAST([1, 2, 3] AS VARCHAR[]);
```

Arrays

Arrays follow the same casting rules as lists. In addition, arrays can be implicitly cast to lists of the same type. For example, an `INTEGER[3]` array can be implicitly cast to an `INTEGER[]` list.

Structs

Structs can be cast to other structs as long as they share at least one field.

> The rationale behind this requirement is to help avoid unintended errors. If two structs do not have any fields in common, then the cast was likely not intended.

```
SELECT CAST({'a': 42} AS STRUCT(a VARCHAR));
```

Fields that exist in the target struct, but that do not exist in the source struct, default to `NULL`.

```
SELECT CAST({'a': 42} AS STRUCT(a VARCHAR, b VARCHAR));
```

Fields that only exist in the source struct are ignored.

```
SELECT CAST({'a': 42, 'b': 43} AS STRUCT(a VARCHAR));
```

The names of the struct can also be in a different order. The fields of the struct will be reshuffled based on the names of the structs.

```
SELECT CAST({'a': 42, 'b': 84} AS STRUCT(b VARCHAR, a VARCHAR));
```

For combination casting, the fields of the resulting struct are the superset of all fields of the input structs. This logic also applies recursively to potentially nested structs.

```
SELECT {'outer1': {'inner1': 42, 'inner2': 42}} AS c
UNION
SELECT {'outer1': {'inner2': 'hello', 'inner3': 'world'}, 'outer2': '100'} AS c;
```

```
SELECT [{'a': 42}, {'b': 84}];
```

Unions

Union casting rules can be found on the `UNION type page`.

Variant Type

The `VARIANT` type stores typed, binary data where each row is self-contained with its own type information. This differs from the JSON type, which is physically stored as text. Because type metadata is embedded per-value, `VARIANT` provides better compression and query performance than JSON for semi-structured data.

The `VARIANT` type is inspired by Snowflake's semi-structured `VARIANT` data type. It is available in Parquet since 2025 and also supported by DuckDB's Parquet reader.

Examples

Storing Different Types in the Same Column

A `VARIANT` column can hold values of different types across rows:

```
CREATE TABLE events (id INTEGER, data VARIANT);
INSERT INTO events VALUES
    (1, 42::VARIANT),
    (2, 'hello world'::VARIANT),
    (3, [1, 2, 3]::VARIANT),
    (4, {'name': 'Alice', 'age': 30}::VARIANT);
```

```
SELECT * FROM events;
```

id int32	data variant
1	42
2	hello world
3	[1, 2, 3]
4	{'name': Alice, 'age': 30}

Checking the Type of a Value

Use `variant_typeof` to inspect the underlying type of each row:

```
SELECT id, data, variant_typeof(data) AS vtype
FROM events;
```

id int32	data variant	vtype varchar
1	42	INT32
2	hello world	VARCHAR
3	[1, 2, 3]	ARRAY(3)
4	{'name': Alice, 'age': 30}	OBJECT(name, age)

Extracting Fields from Nested Variants

Fields can be extracted from nested `VARIANT` values using dot notation or the `variant_extract` function:

```
SELECT data.name FROM events WHERE id = 4;
```

```
SELECT variant_extract(data, 'name') AS name FROM events WHERE id = 4;
```

name variant
Alice

Parquet Support

DuckDB supports reading and writing `VARIANT` types from Parquet files, including *shredding,* a technique that stores nested data as flat values for more efficient access.

Writing VARIANT to Parquet

When writing `VARIANT` columns to Parquet, DuckDB can automatically shred (decompose) the variant data into typed columns based on the structure of the first row group. This auto-shredding improves read performance by enabling predicate pushdown and efficient column access.

To explicitly provide a schema for shredding, use the `SHREDDING` copy option:

```
COPY events TO 'events.parquet' (
    FORMAT parquet,
    SHREDDING {'data': 'STRUCT(name VARCHAR, age INTEGER)'}
);
```

Reading Snowflake VARIANT from Parquet

DuckDB can read shredded `VARIANT` Parquet files produced by Snowflake, automatically reconstructing the variant values from the shredded columns.

Expressions

Expressions

An expression is a combination of values, operators and functions. Expressions are highly composable, and range from very simple to arbitrarily complex. They can be found in many different parts of SQL statements. This section describes the different types of operators and functions that can be used within expressions.

CASE Expression

The CASE expression performs a switch based on a condition. The basic form is identical to the ternary condition used in many programming languages (`CASE WHEN cond THEN a ELSE b END` is equivalent to `cond ? a : b`). With a single condition this can be expressed with `IF(cond, a, b)`.

```
CREATE OR REPLACE TABLE integers AS SELECT unnest([1, 2, 3]) AS i;
SELECT i, CASE WHEN i > 2 THEN 1 ELSE 0 END AS test
FROM integers;
```

i	test
1	0
2	0
3	1

This is equivalent to:

```
SELECT i, IF(i > 2, 1, 0) AS test
FROM integers;
```

The `WHEN cond THEN expr` part of the CASE expression can be chained, whenever any of the conditions returns true for a single tuple, the corresponding expression is evaluated and returned.

```
CREATE OR REPLACE TABLE integers AS SELECT unnest([1, 2, 3]) AS i;
SELECT i, CASE WHEN i = 1 THEN 10 WHEN i = 2 THEN 20 ELSE 0 END AS test
FROM integers;
```

i	test
1	10
2	20
3	0

The `ELSE` clause of the CASE expression is optional. If no `ELSE` clause is provided and none of the conditions match, the CASE expression will return `NULL`.

```
CREATE OR REPLACE TABLE integers AS SELECT unnest([1, 2, 3]) AS i;
SELECT i, CASE WHEN i = 1 THEN 10 END AS test
FROM integers;
```

i	test
1	10
2	NULL
3	NULL

It is also possible to provide an individual expression after the CASE but before the WHEN. When this is done, the CASE expression is effectively transformed into a `switch` statement.

```
CREATE OR REPLACE TABLE integers AS SELECT unnest([1, 2, 3]) AS i;
SELECT i, CASE i WHEN 1 THEN 10 WHEN 2 THEN 20 WHEN 3 THEN 30 END AS test
FROM integers;
```

i	test
1	10
2	20
3	30

This is equivalent to:

```
SELECT i, CASE WHEN i = 1 THEN 10 WHEN i = 2 THEN 20 WHEN i = 3 THEN 30 END AS test
FROM integers;
```

SWITCH Expression

The SWITCH expression is syntactic sugar for the CASE expression. It takes an expression, a MAP of values to results, and an optional default value.

```
CREATE OR REPLACE TABLE integers AS SELECT unnest([1, 2, 3]) AS i;
SELECT i, SWITCH(i, MAP {1: 'one', 2: 'two', 3: 'three'}) AS test
FROM integers;
```

i	test
1	one
2	two
3	three

A default value can be provided as the third argument, which is returned when none of the map keys match:

```
SELECT i, SWITCH(i, MAP {1: 'one', 2: 'two'}, 'other') AS test
FROM integers;
```

i	test
1	one
2	two
3	other

Casting

Casting refers to the operation of converting a value in a particular data type to the corresponding value in another data type. Casting can occur either implicitly or explicitly. The syntax described here performs an explicit cast. More information on casting can be found on the typecasting page.

Explicit Casting

The standard SQL syntax for explicit casting is `CAST(expr AS TYPENAME)`, where `TYPENAME` is a name (or alias) of one of DuckDB's data types. DuckDB also supports the shorthand `expr::TYPENAME`, which is also present in PostgreSQL.

```
SELECT CAST(i AS VARCHAR) AS i
FROM generate_series(1, 3) tbl(i);
```

i
1
2
3

```
SELECT i::DOUBLE AS i
FROM generate_series(1, 3) tbl(i);
```

i
1.0
2.0
3.0

Casting Rules

Not all casts are possible. For example, it is not possible to convert an `INTEGER` to a `DATE`. Casts may also throw errors when the cast could not be successfully performed. For example, trying to cast the string `'hello'` to an `INTEGER` will result in an error being thrown.

```
SELECT CAST('hello' AS INTEGER);
```

```
Conversion Error:
Could not convert string 'hello' to INT32
```

The exact behavior of the cast depends on the source and destination types. For example, when casting from `VARCHAR` to any other type, the string will be attempted to be converted.

Casting between numeric types might have rounding implications. The applicable rounding rules can be found on the `NUMERIC` type page.

TRY_CAST

TRY_CAST can be used when the preferred behavior is not to throw an error, but instead to return a NULL value. TRY_CAST will never throw an error, and will instead return NULL if a cast is not possible.

```
SELECT TRY_CAST('hello' AS INTEGER) AS i;
```

i
NULL

`cast_to_type` Function

The `cast_to_type` function allows generating a cast from an expression to the type of another column. For example:

```
SELECT cast_to_type('42', NULL::INTEGER) AS result;
```

res
int32
42

This function is primarily useful in macros, as it allows you to maintain types. This helps with making generic macros that operate on different types. For example, the following macro adds to a number if the input is an `INTEGER`:

```
CREATE TABLE tbl (i INT, s VARCHAR);
INSERT INTO tbl VALUES (42, 'hello world');

CREATE MACRO conditional_add(col, nr) AS
    CASE
        WHEN typeof(col) == 'INTEGER' THEN cast_to_type(col::INTEGER + nr, col)
        ELSE col
    END;
SELECT conditional_add(COLUMNS(*), 100) FROM tbl;
```

i	s
int32	varchar
142	hello world

Note that the CASE statement needs to return the same type in all code paths. We can perform the addition on any input column by adding a cast to the desired type – but we need to cast the result of the addition back to the source type to make the binding work.

Collations

Collations provide rules for how text should be sorted or compared in the execution engine. Collations are useful for localization, as the rules for how text should be ordered are different for different languages or for different countries. These orderings are often incompatible with one another. For example, in English the letter `y` comes between `x` and `z`. However, in Lithuanian the letter `y` comes between the `i` and `j`. For that reason, different collations are supported. The user must choose which collation they want to use when performing sorting and comparison operations.

By default, the `BINARY` collation is used. That means that strings are ordered and compared based only on their binary contents. This makes sense for standard ASCII characters (i.e., the letters A-Z and numbers 0-9), but generally does not make much sense for special

unicode characters. It is, however, by far the fastest method of performing ordering and comparisons. Hence it is recommended to stick with the `BINARY` collation unless required otherwise.

> The `BINARY` collation is also available under the aliases `C` and `POSIX`.

> **Warning.** Collation support in DuckDB has some known limitations and has several planned improvements.

Using Collations

In the stand-alone installation of DuckDB three collations are included: `NOCASE`, `NOACCENT` and `NFC`. The `NOCASE` collation compares characters as equal regardless of their casing. The `NOACCENT` collation compares characters as equal regardless of their accents. The `NFC` collation performs NFC-normalized comparisons, see Unicode normalization for more information.

```
SELECT 'hello' = 'hElLO';
```

```
false
```

```
SELECT 'hello' COLLATE NOCASE = 'hElLO';
```

```
true
```

```
SELECT 'hello' = 'hëllo';
```

```
false
```

```
SELECT 'hello' COLLATE NOACCENT = 'hëllo';
```

```
true
```

Collations can be combined by chaining them using the dot operator. Note, however, that not all collations can be combined together. In general, the `NOCASE` collation can be combined with any other collator, but most other collations cannot be combined.

```
SELECT 'hello' COLLATE NOCASE = 'hElLÖ';
```

```
false
```

```
SELECT 'hello' COLLATE NOACCENT = 'hElLÖ';
```

```
false
```

```
SELECT 'hello' COLLATE NOCASE.NOACCENT = 'hElLÖ';
```

```
true
```

Default Collations

The collations we have seen so far have all been specified *per expression*. It is also possible to specify a default collator, either on the global database level or on a base table column. The `PRAGMA default_collation` can be used to specify the global default collator. This is the collator that will be used if no other one is specified.

```
SET default_collation = NOCASE;
SELECT 'hello' = 'HeLlo';
```

```
true
```

Collations can also be specified per-column when creating a table. When that column is then used in a comparison, the per-column collation is used to perform that comparison.

```
CREATE TABLE names (name VARCHAR COLLATE NOACCENT);
INSERT INTO names VALUES ('hännes');
```

```
SELECT name
FROM names
WHERE name = 'hannes';
```

```
hännes
```

Be careful here, however, as different collations cannot be combined. This can be problematic when you want to compare columns that have a different collation specified.

```
SELECT name
FROM names
WHERE name = 'hannes' COLLATE NOCASE;
```

```
ERROR: Cannot combine types with different collation!
```

```
CREATE TABLE other_names (name VARCHAR COLLATE NOCASE);
INSERT INTO other_names VALUES ('HÄNNES');
```

```
SELECT names.name AS name, other_names.name AS other_name
FROM names, other_names
WHERE names.name = other_names.name;
```

```
ERROR: Cannot combine types with different collation!
```

We need to manually overwrite the collation:

```
SELECT names.name AS name, other_names.name AS other_name
FROM names, other_names
WHERE names.name COLLATE NOACCENT.NOCASE = other_names.name COLLATE NOACCENT.NOCASE;
```

name	other_name
hännes	HÄNNES

ICU Collations

The collations we have seen so far are not region-dependent, and do not follow any specific regional rules. If you wish to follow the rules of a specific region or language, you will need to use one of the ICU collations. For that, you need to load the ICU extension.

Loading this extension will add a number of language and region specific collations to your database. These can be queried using the `PRAGMA collations` command, or by querying the `pragma_collations` function.

```
PRAGMA collations;
SELECT list(collname) FROM pragma_collations();
```

```
[af, am, ar, ar_sa, as, az, be, bg, bn, bo, br, bs, ca, ceb, chr, cs, cy, da, de, de_at, dsb, dz, ee, el,
en, en_us, eo, es, et, fa, fa_af, ff, fi, fil, fo, fr, fr_ca, fy, ga, gl, gu, ha, haw, he, he_il, hi, hr,
hsb, hu, hy, icu_noaccent, id, id_id, ig, is, it, ja, ka, kk, kl, km, kn, ko, kok, ku, ky, lb, lkt, ln,
lo, lt, lv, mk, ml, mn, mr, ms, mt, my, nb, nb_no, ne, nfc, nl, nn, noaccent, nocase, om, or, pa, pa_in,
pl, ps, pt, ro, ru, sa, se, si, sk, sl, smn, sq, sr, sr_ba, sr_me, sr_rs, sv, sw, ta, te, th, tk, to, tr,
ug, uk, ur, uz, vi, wae, wo, xh, yi, yo, yue, yue_cn, zh, zh_cn, zh_hk, zh_mo, zh_sg, zh_tw, zu]
```

These collations can then be used as the other collations would be used before. They can also be combined with the NOCASE collation. For example, to use the German collation rules you could use the following code snippet:

```
CREATE TABLE strings (s VARCHAR COLLATE DE);
INSERT INTO strings VALUES ('Gabel'), ('Göbel'), ('Goethe'), ('Goldmann'), ('Göthe'), ('Götz');
SELECT * FROM strings ORDER BY s;
```

```
"Gabel", "Göbel", "Goethe", "Goldmann", "Göthe", "Götz"
```

Comparisons

Comparison Operators

The table below shows the standard comparison operators. Whenever either of the input arguments is `NULL`, the output of the comparison is `NULL`.

Operator	Description	Example	Result
<	less than	`2 < 3`	`true`
>	greater than	`2 > 3`	`false`
<=	less than or equal to	`2 <= 3`	`true`
>=	greater than or equal to	`4 >= NULL`	`NULL`
= or ==	equal	`NULL = NULL`	`NULL`
<> or !=	not equal	`2 <> 2`	`false`

The table below shows the standard distinction operators. These operators treat `NULL` values as equal.

Operator	Description	Example	Result
`IS DISTINCT FROM`	not equal, including `NULL`	`2 IS DISTINCT FROM NULL`	`true`
`IS NOT DISTINCT FROM`	equal, including `NULL`	`NULL IS NOT DISTINCT FROM NULL`	`true`

Combination Casting

When performing comparison on different types, DuckDB performs Combination Casting. These casts were introduced to make interactive querying more convenient and are in line with the casts performed by several programming languages but are often not compatible with PostgreSQL's behavior. For example, the following expressions evaluate and return `true` in DuckDB but fail in PostgreSQL.

```
SELECT 1 = true;
SELECT 1 = '1.1';
```

> It is not possible to enforce stricter type-checking for DuckDB's comparison operators. If you require stricter type-checking, consider creating a macro with the `typeof` function or implementing a user-defined function.

`BETWEEN` and `IS [NOT] NULL`

Besides the standard comparison operators there are also the `BETWEEN` and `IS (NOT) NULL` operators. These behave much like operators, but have special syntax mandated by the SQL standard. They are shown in the table below.

Note that `BETWEEN` and `NOT BETWEEN` are only equivalent to the examples below in the cases where both `a`, `x` and `y` are of the same type, as `BETWEEN` will cast all of its inputs to the same type.

Predicate	Description
`a BETWEEN x AND y`	equivalent to `x <= a AND a <= y`
`a NOT BETWEEN x AND y`	equivalent to `x > a OR a > y`
`expression IS NULL`	`true` if expression is `NULL`, `false` otherwise

Predicate	Description
`expression ISNULL`	alias for `IS NULL` (non-standard)
`expression IS NOT NULL`	`false` if expression is `NULL`, `true` otherwise
`expression NOTNULL`	alias for `IS NOT NULL` (non-standard)

> For the expression `BETWEEN x AND y`, `x` is used as the lower bound and `y` is used as the upper bound. Therefore, if `x > y`, the result will always be `false`.

IN Operator

The `IN` operator checks containment of the left expression inside the *collection* on the right hand side (RHS). Supported collections on the RHS are tuples, lists, and maps, as well as subqueries that return a single column. The single-column restriction applies only to subqueries; tuples, lists, and maps may themselves contain composite values.

`IN (val1, val2, ...)` (Tuple)

The `IN` operator on a tuple `(val1, val2, ...)` returns `true` if the expression is present in the RHS, `false` if the expression is not in the RHS and the RHS has no `NULL` values, or `NULL` if the expression is not in the RHS and the RHS has `NULL` values.

```
SELECT 'Math' IN ('CS', 'Math');
```

```
true
```

```
SELECT 'English' IN ('CS', 'Math');
```

```
false
```

```
SELECT 'Math' IN ('CS', 'Math', NULL);
```

```
true
```

```
SELECT 'English' IN ('CS', 'Math', NULL);
```

```
NULL
```

`IN [val1, val2, ...]` (List)

The `IN` operator works on lists according to the semantics used in Python. Unlike for the `IN tuple` operator, the presence of `NULL` values on the right hand side of the expression does not make a difference in the result:

```
SELECT 'Math' IN ['CS', 'Math', NULL];
```

```
true
```

```
SELECT 'English' IN ['CS', 'Math', NULL];
```

```
false
```

`IN` Map

The `IN` operator works on maps according to the semantics used in Python, i.e., it checks for the presence of keys (not values):

```
SELECT 'key1' IN MAP {'key1': 50, 'key2': 75};
```

```
true
```

```
SELECT 'key3' IN MAP {'key1': 50, 'key2': 75};
```

```
false
```

IN Subquery

The `IN` operator works with subqueries that return a single column. For example:

```
SELECT 42 IN (SELECT unnest([32, 42, 52]) AS x);
```

```
true
```

If the subquery returns more than one column, a Binder Error is thrown:

```
SELECT 42 IN (SELECT unnest([32, 42, 52]) AS x, 'a' AS y);
```

```
Binder Error:
Subquery returns 2 columns - expected 1
```

IN String

The `IN` operator can be used as a shorthand for the `contains` string function. For example:

```
SELECT 'Hello' IN 'Hello World';
```

```
true
```

NOT IN

`NOT IN` can be used to check if an element is not present in the set. `x NOT IN y` is equivalent to `NOT (x IN y)`.

Logical Operators

The following logical operators are available: `AND`, `OR` and `NOT`. SQL uses a three-valued logic system with `true`, `false` and `NULL`. Note that logical operators involving `NULL` do not always evaluate to `NULL`. For example, `NULL AND false` will evaluate to `false`, and `NULL OR true` will evaluate to `true`. Below are the complete truth tables.

Binary Operators: AND and OR

a	b	a AND b	a OR b
true	true	true	true
true	false	false	true
true	NULL	NULL	true
false	false	false	false
false	NULL	false	NULL
NULL	NULL	NULL	NULL

Unary Operator: NOT

a	NOT a
true	false
false	true
NULL	NULL

The operators AND and OR are commutative, that is, you can switch the left and right operand without affecting the result.

Star Expression

Syntax

The * expression can be used in a SELECT statement to select all columns that are projected in the FROM clause.

```
SELECT *
FROM tbl;
```

TABLE.* and STRUCT.*

The * expression can be prepended by a table name to select only columns from that table.

```
SELECT tbl.*
FROM tbl
JOIN other_tbl USING (id);
```

Similarly, the * expression can also be used to retrieve all keys from a struct as separate columns. This is particularly useful when a prior operation creates a struct of unknown shape, or if a query must handle any potential struct keys. See the STRUCT data type and STRUCT functions pages for more details on working with structs.

For example:

```
SELECT st.* FROM (SELECT {'x': 1, 'y': 2, 'z': 3} AS st);
```

x	y	z
1	2	3

EXCLUDE Clause

EXCLUDE allows you to exclude specific columns from the * expression.

```
SELECT * EXCLUDE (col)
FROM tbl;
```

REPLACE Clause

REPLACE allows you to replace specific columns by alternative expressions.

```
SELECT * REPLACE (col1 / 1_000 AS col1, col2 / 1_000 AS col2)
FROM tbl;
```

RENAME Clause

RENAME allows you to replace specific columns.

```
SELECT * RENAME (col1 AS height, col2 AS width)
FROM tbl;
```

Column Filtering via Pattern Matching Operators

The pattern matching operators `LIKE`, `GLOB`, `SIMILAR TO` and their variants allow you to select columns by matching their names to patterns.

```
SELECT * LIKE 'col%'
FROM tbl;
```

```
SELECT * GLOB 'col*'
FROM tbl;
```

```
SELECT * SIMILAR TO 'col.'
FROM tbl;
```

The NOT variants of these operators are also supported to exclude columns that match the pattern:

```
SELECT * NOT SIMILAR TO 'col.'
FROM tbl;
```

COLUMNS Expression

The COLUMNS expression is similar to the regular star expression, but additionally allows you to execute the same expression on the resulting columns.

```
CREATE TABLE numbers (id INTEGER, number INTEGER);
INSERT INTO numbers VALUES (1, 10), (2, 20), (3, NULL);
SELECT min(COLUMNS(*)), count(COLUMNS(*)) FROM numbers;
```

id	number	id	number
1	10	3	2

```
SELECT
    min(COLUMNS(* REPLACE (number + id AS number))),
    count(COLUMNS(* EXCLUDE (number)))
FROM numbers;
```

id	min(number := (number + id))	id
1	11	3

COLUMNS expressions can also be combined, as long as they contain the same star expression:

```
SELECT COLUMNS(*) + COLUMNS(*) FROM numbers;
```

id	number
2	20

id	number
4	40
6	NULL

`COLUMNS` Expression in a `WHERE` Clause

`COLUMNS` expressions can also be used in `WHERE` clauses. The conditions are applied to all columns and are combined using the logical `AND` operator.

```
SELECT *
FROM (
    SELECT 'a', 'a'
    UNION ALL
    SELECT 'a', 'b'
    UNION ALL
    SELECT 'b', 'b'
) _(x, y)
WHERE COLUMNS(*) = 'a'; -- equivalent to: x = 'a' AND y = 'a'
```

x	y
a	a

To combine conditions using the logical `OR` operator, you can `UNPACK` the `COLUMNS` expression into the variadic `greatest` function.

```
SELECT *
FROM (
    SELECT 'a', 'a'
    UNION ALL
    SELECT 'a', 'b'
    UNION ALL
    SELECT 'b', 'b'
) _(x, y)
WHERE greatest(UNPACK(COLUMNS(*) = 'a')); -- equivalent to: x = 'a' OR y = 'a'
```

x	y
a	a
a	b

`COLUMNS` Expression in `DISTINCT ON`

`COLUMNS` expressions can be used in `DISTINCT ON` clauses to specify distinct columns by pattern:

```
SELECT DISTINCT ON (COLUMNS('x|y')) *
FROM (VALUES (1, 2, 'a'), (1, 2, 'b'), (3, 4, 'c')) t(x, y, z);
```

x	y	z
1	2	a
3	4	c

x	y	z

Regular Expressions in a COLUMNS Expression

COLUMNS expressions don't currently support the pattern matching operators, but they do support regular expression matching by simply passing a string constant in place of the star:

```
SELECT COLUMNS('(id|numbers?)') FROM numbers;
```

id	number
1	10
2	20
3	NULL

Renaming Columns with Regular Expressions in a COLUMNS Expression

The matches of capture groups in regular expressions can be used to rename matching columns. The capture groups are one-indexed; `\0` is the original column name.

For example, to select the first three letters of column names, run:

```
SELECT COLUMNS('(\w{3}).*') AS '\1' FROM numbers;
```

id	num
1	10
2	20
3	NULL

To remove a colon (`:`) character in the middle of a column name, run:

```
CREATE TABLE tbl ("Foo:Bar" INTEGER, "Foo:Baz" INTEGER, "Foo:Qux" INTEGER);
SELECT COLUMNS('(\w*):(\w*)') AS '\1\2' FROM tbl;
```

To add the original column name to the expression alias, run:

```
SELECT min(COLUMNS(*)) AS "min_\0" FROM numbers;
```

min_id	min_number
1	10

COLUMNS Lambda Function

COLUMNS also supports passing in a lambda function. The lambda function will be evaluated for all columns present in the FROM clause, and only columns that match the lambda function will be returned. This allows the execution of arbitrary expressions in order to select and rename columns.

```
SELECT COLUMNS(lambda c: c LIKE '%num%') FROM numbers;
```

number
10
20
NULL

COLUMNS List

COLUMNS also supports passing in a list of column names.

```
SELECT COLUMNS(['id', 'num']) FROM numbers;
```

id	num
1	10
2	20
3	NULL

Unpacking a COLUMNS Expression

By wrapping a COLUMNS expression in UNPACK, the columns expand into a parent expression, much like the iterable unpacking behavior in Python.

Without UNPACK, operations on the COLUMNS expression are applied to each column separately:

```
SELECT coalesce(COLUMNS(['a', 'b', 'c'])) AS result
FROM (SELECT NULL a, 42 b, true c);
```

result	result	result
NULL	42	true

With UNPACK, the COLUMNS expression is expanded into its parent expression, `coalesce` in the example above, which results in a single column:

```
SELECT coalesce(UNPACK(COLUMNS(['a', 'b', 'c']))) AS result
FROM (SELECT NULL AS a, 42 AS b, true AS c);
```

result
42

The UNPACK keyword may be replaced by `*`, matching Python syntax, when it is applied directly to the COLUMNS expression without any intermediate operations.

```
SELECT coalesce(*COLUMNS(*)) AS result
FROM (SELECT NULL a, 42 AS b, true AS c);
```

result
42

> **Warning.** In the following example, replacing UNPACK by * results in a syntax error:
>
> ```
> SELECT greatest(UNPACK(COLUMNS(*) + 1)) AS result
> FROM (SELECT 1 AS a, 2 AS b, 3 AS c);
> ```
>
result
4

STRUCT.*

The * expression can also be used to retrieve all keys from a struct as separate columns. This is particularly useful when a prior operation creates a struct of unknown shape, or if a query must handle any potential struct keys. See the STRUCT data type and STRUCT functions pages for more details on working with structs.

For example:

```
SELECT st.* FROM (SELECT {'x': 1, 'y': 2, 'z': 3} AS st);
```

x	y	z
1	2	3

Subqueries

Subqueries are parenthesized query expressions that appear as part of a larger, outer query. Subqueries are usually based on `SELECT ... FROM`, but in DuckDB other query constructs such as `PIVOT` can also appear as a subquery.

Scalar Subquery

Scalar subqueries are subqueries that return a single value. They can be used anywhere where an expression can be used. If a scalar subquery returns more than a single value, an error is raised (unless `scalar_subquery_error_on_multiple_rows` is set to `false`, in which case a row is selected randomly).

Consider the following table:

Grades

grade	course
7	Math
9	Math
8	CS

```
CREATE TABLE grades (grade INTEGER, course VARCHAR);
INSERT INTO grades VALUES (7, 'Math'), (9, 'Math'), (8, 'CS');
```

We can run the following query to obtain the minimum grade:

```
SELECT min(grade) FROM grades;
```

min(grade)
7

By using a scalar subquery in the WHERE clause, we can figure out for which course this grade was obtained:

```
SELECT course FROM grades WHERE grade = (SELECT min(grade) FROM grades);
```

course
Math

ARRAY Subqueries

Subqueries that return multiple values can be wrapped with ARRAY to collect all results in a list.

```
SELECT ARRAY(SELECT grade FROM grades) AS all_grades;
```

all_grades
[7, 9, 8]

Subquery Comparisons: ALL, ANY and SOME

In the section on scalar subqueries, a scalar expression was compared directly to a subquery using the equality comparison operator (=). Such direct comparisons only make sense with scalar subqueries.

Scalar expressions can still be compared to single-column subqueries returning multiple rows by specifying a quantifier. Available quantifiers are ALL, ANY and SOME. The quantifiers ANY and SOME are equivalent.

ALL

The ALL quantifier specifies that the comparison as a whole evaluates to `true` when the individual comparison results of *the expression at the left hand side of the comparison operator* with each of the values from *the subquery at the right hand side of the comparison operator* **all** evaluate to `true`:

```
SELECT 6 <= ALL (SELECT grade FROM grades) AS adequate;
```

returns:

adequate
true

because 6 is less than or equal to each of the subquery results 7, 8 and 9.

However, the following query

```
SELECT 8 >= ALL (SELECT grade FROM grades) AS excellent;
```

returns

excellent
false

because 8 is not greater than or equal to the subquery result 9. And thus, because not all comparisons evaluate to `true`, `>= ALL` as a whole evaluates to `false`.

ANY

The `ANY` quantifier specifies that the comparison as a whole evaluates to `true` when at least one of the individual comparison results evaluates to `true`. For example:

```
SELECT 5 >= ANY (SELECT grade FROM grades) AS fail;
```

returns

fail
false

because no result of the subquery is less than or equal to 5.

The quantifier `SOME` may be used instead of `ANY`: `ANY` and `SOME` are interchangeable.

EXISTS

The `EXISTS` operator tests for the existence of any row inside the subquery. It returns either true when the subquery returns one or more records, and false otherwise. The `EXISTS` operator is generally the most useful as a *correlated* subquery to express semijoin operations. However, it can be used as an uncorrelated subquery as well.

For example, we can use it to figure out if there are any grades present for a given course:

```
SELECT EXISTS (FROM grades WHERE course = 'Math') AS math_grades_present;
```

math_grades_present
true

```
SELECT EXISTS (FROM grades WHERE course = 'History') AS history_grades_present;
```

history_grades_present
false

> The subqueries in the examples above make use of the fact that you can omit the `SELECT *` in DuckDB thanks to the FROM-first syntax. The `SELECT` clause is required in subqueries by other SQL systems but cannot fulfill any purpose in `EXISTS` and `NOT EXISTS` subqueries.

NOT EXISTS

The `NOT EXISTS` operator tests for the absence of any row inside the subquery. It returns either true when the subquery returns an empty result, and false otherwise. The `NOT EXISTS` operator is generally the most useful as a *correlated* subquery to express antijoin operations. For example, to find Person nodes without an interest:

```
CREATE TABLE Person (id BIGINT, name VARCHAR);
CREATE TABLE interest (PersonId BIGINT, topic VARCHAR);

INSERT INTO Person VALUES (1, 'Jane'), (2, 'Joe');
INSERT INTO interest VALUES (2, 'Music');

SELECT *
FROM Person
WHERE NOT EXISTS (FROM interest WHERE interest.PersonId = Person.id);
```

id	name
1	Jane

> DuckDB automatically detects when a `NOT EXISTS` query expresses an antijoin operation. There is no need to manually rewrite such queries to use `LEFT OUTER JOIN ... WHERE ... IS NULL`.

IN Operator

The `IN` operator checks containment of the left expression inside the result defined by the subquery or the set of expressions on the right hand side (RHS). The `IN` operator returns true if the expression is present in the RHS, false if the expression is not in the RHS and the RHS has no `NULL` values, or `NULL` if the expression is not in the RHS and the RHS has `NULL` values.

We can use the `IN` operator in a similar manner as we used the `EXISTS` operator:

```
SELECT 'Math' IN (SELECT course FROM grades) AS math_grades_present;
```

math_grades_present
true

Correlated Subqueries

All the subqueries presented here so far have been **uncorrelated** subqueries, where the subqueries themselves are entirely self-contained and can be run without the parent query. There exists a second type of subqueries called **correlated** subqueries. For correlated subqueries, the subquery uses values from the parent subquery.

Conceptually, the subqueries are run once for every single row in the parent query. Perhaps a simple way of envisioning this is that the correlated subquery is a **function** that is applied to every row in the source dataset.

For example, suppose that we want to find the minimum grade for every course. We could do that as follows:

```
SELECT *
FROM grades grades_parent
WHERE grade =
    (SELECT min(grade)
     FROM grades
     WHERE grades.course = grades_parent.course);
```

grade	course
7	Math
8	CS

The subquery uses a column from the parent query (`grades_parent.course`). Conceptually, we can see the subquery as a function where the correlated column is a parameter to that function:

```
SELECT min(grade)
FROM grades
WHERE course = ?;
```

Now when we execute this function for each of the rows, we can see that for `Math` this will return `7`, and for `CS` it will return `8`. We then compare it against the grade for that actual row. As a result, the row `(Math, 9)` will be filtered out, as `9 <> 7`.

Returning Each Row of the Subquery as a Struct

Using the name of a subquery in the `SELECT` clause (without referring to a specific column) turns each row of the subquery into a struct whose fields correspond to the columns of the subquery. For example:

```
SELECT t
FROM (SELECT unnest(generate_series(41, 43)) AS x, 'hello' AS y) t;
```

t
{'x': 41, 'y': hello}
{'x': 42, 'y': hello}
{'x': 43, 'y': hello}

TRY Expression

The TRY expression ensures that errors caused by the input rows in the child (scalar) expression result in `NULL` for those rows, instead of causing the query to throw an error.

> The TRY expression was inspired by the TRY_CAST expression.

Examples

The following calls return errors when invoked without the TRY expression. When they are wrapped into a TRY expression, they return `NULL`:

Casting

Without TRY

```
SELECT 'abc'::INTEGER;
```

```
Conversion Error:
Could not convert string 'abc' to INT32
```

With TRY

```
SELECT TRY('abc'::INTEGER);
```

```
NULL
```

Logarithm on Zero

Without TRY

```
SELECT ln(0);
```

```
Out of Range Error:
cannot take logarithm of zero
```

With TRY

```
SELECT TRY(ln(0));
```

```
NULL
```

Casting Multiple Rows

Without TRY

```
WITH cte AS (FROM (VALUES ('123'), ('test'), ('235')) t(a))
SELECT a::INTEGER AS x FROM cte;
```

```
Conversion Error:
Could not convert string 'test' to INT32
```

With TRY

```
WITH cte AS (FROM (VALUES ('123'), ('test'), ('235')) t(a))
SELECT TRY(a::INTEGER) AS x FROM cte;
```

x
123
NULL
235

Limitations

TRY cannot be used in combination with a volatile function, an aggregate function, or a scalar subquery. For example:

```
SELECT TRY(random())
```

```
Binder Error:
TRY can not be used in combination with a volatile function
```

Functions

Functions

Function Syntax

Function Chaining via the Dot Operator

DuckDB supports the dot syntax for function chaining. This allows the function call `fn(arg1, arg2, arg3, ...)` to be rewritten as `arg1.fn(arg2, arg3, ...)`. For example, take the following use of the `replace` function:

```
SELECT replace(goose_name, 'goose', 'duck') AS duck_name
FROM unnest(['African goose', 'Faroese goose', 'Hungarian goose', 'Pomeranian goose']) breed(goose_name);
```

This can be rewritten as follows:

```
SELECT goose_name.replace('goose', 'duck') AS duck_name
FROM unnest(['African goose', 'Faroese goose', 'Hungarian goose', 'Pomeranian goose']) breed(goose_name);
```

Using with Literals and Arrays

To apply function chaining to literals and following array access operations, you must surround the argument with parentheses, e.g.:

```
SELECT ('hello world').replace(' ', '_');
```

```
SELECT (2).sqrt();
```

```
SELECT (m[1]).map_entries()
FROM (VALUES ([MAP {'hello': 42}, MAP {'world': 42}])) t(m);
```

In the absence of these parentheses, DuckDB will return a `Parser Error` for the function call:

```
Parser Error:
syntax error at or near "("
```

Limitations

Function chaining via the dot operator is limited to *scalar* functions and is not supported for *table* functions. For example, the following call returns a `Parser Error`:

```
SELECT * FROM ('my_file.parquet').read_parquet(); -- does not work
```

Additionally, the functions `coalesce` and `ifnull` cannot be used with function chaining for the time being:

```
SELECT (2).coalesce(0); -- does not work
SELECT (2).ifnull(0); -- does not work
```

Query Functions

The `duckdb_functions()` table function shows the list of functions currently built into the system.

```
SELECT DISTINCT ON(function_name)
    function_name,
    function_type,
    return_type,
    parameters,
    parameter_types,
    description
FROM duckdb_functions()
WHERE function_type = 'scalar'
  AND function_name LIKE 'b%'
ORDER BY function_name;
```

function_name	function_type	return_type	parameters	parameter_types	description
bar	scalar	VARCHAR	[x, min, max, width]	[DOUBLE, DOUBLE, DOUBLE, DOUBLE]	Draws a band whose width is proportional to (x - min) and equal to width characters when x = max. width defaults to 80
base64	scalar	VARCHAR	[blob]	[BLOB]	Convert a blob to a base64 encoded string
bin	scalar	VARCHAR	[value]	[VARCHAR]	Converts the value to binary representation
bit_count	scalar	TINYINT	[x]	[TINYINT]	Returns the number of bits that are set
bit_length	scalar	BIGINT	[col0]	[VARCHAR]	Number of bits in a string
bit_position	scalar	INTEGER	[substring, bitstring]	[BIT, BIT]	Returns first starting index of the specified substring within bits, or zero if it is not present. The first (leftmost) bit is indexed 1
bitstring	scalar	BIT	[bitstring, length]	[VARCHAR, INTEGER]	Pads the bitstring until the specified length

> Currently, the description and parameter names of functions are not available in the `duckdb_functions()` function.

Aggregate Functions

Examples

Produce a single row containing the sum of the `amount` column:

```
SELECT sum(amount)
FROM sales;
```

Produce one row per unique region, containing the sum of `amount` for each group:

```
SELECT region, sum(amount)
FROM sales
GROUP BY region;
```

Return only the regions that have a sum of `amount` higher than 100:

```
SELECT region
FROM sales
GROUP BY region
HAVING sum(amount) > 100;
```

Return the number of unique values in the `region` column:

```
SELECT count(DISTINCT region)
FROM sales;
```

Return two values, the total sum of `amount` and the sum of `amount` minus columns where the region is `north` using the `FILTER` clause:

```
SELECT sum(amount), sum(amount) FILTER (region != 'north')
FROM sales;
```

Returns a list of all regions in order of the `amount` column:

```
SELECT list(region ORDER BY amount DESC)
FROM sales;
```

Returns the amount of the first sale using the `first()` aggregate function:

```
SELECT first(amount ORDER BY date ASC)
FROM sales;
```

Syntax

Aggregates are functions that *combine* multiple rows into a single value. Aggregates are different from scalar functions and window functions because they change the cardinality of the result. As such, aggregates can only be used in the `SELECT` and `HAVING` clauses of a SQL query.

`DISTINCT` Clause in Aggregate Functions

When the `DISTINCT` clause is provided, only distinct values are considered in the computation of the aggregate. This is typically used in combination with the `count` aggregate to get the number of distinct elements; but it can be used together with any aggregate function in the system. There are some aggregates that are insensitive to duplicate values (e.g., `min` and `max`) and for them this clause is parsed and ignored.

`ORDER BY` Clause in Aggregate Functions

An `ORDER BY` clause can be provided after the last argument of the function call. Note the lack of the comma separator before the clause.

```
SELECT <aggregate_function>(<arg>, <sep> ORDER BY <ordering_criteria>);
```

This clause ensures that the values being aggregated are sorted before applying the function. Most aggregate functions are order-insensitive, and for them this clause is parsed and discarded. However, there are some order-sensitive aggregates that can have non-deterministic results without ordering, e.g., `first`, `last`, `list` and `string_agg` / `group_concat` / `listagg`. These can be made deterministic by ordering the arguments.

For example:

```
CREATE TABLE tbl AS
    SELECT s FROM range(1, 4) r(s);

SELECT string_agg(s, ', ' ORDER BY s DESC) AS countdown
FROM tbl;
```

countdown
3, 2, 1

Handling NULL Values

All general aggregate functions ignore NULLs, except for `list` (`array_agg`), `first` (`arbitrary`) and `last`. To exclude NULLs from `list`, you can use a `FILTER` clause. To ignore NULLs from `first`, you can use the `any_value` aggregate.

All general aggregate functions except `count` return `NULL` on empty groups. In particular, `list` does *not* return an empty list, `sum` does *not* return zero, and `string_agg` does *not* return an empty string in this case.

General Aggregate Functions

The table below shows the available general aggregate functions.

Function	Description
`any_value(arg)`	Returns the first non-null value from `arg`. This function is affected by ordering.
`arg_max(arg, val)`	Finds the row with the maximum `val` and calculates the `arg` expression at that row. Rows where the value of the `arg` or `val` expression is `NULL` are ignored. This function is affected by ordering.
`arg_max(arg, val, n)`	The generalized case of `arg_max` for n values: returns a `LIST` containing the `arg` expressions for the top n rows ordered by `val` descending. This function is affected by ordering.
`arg_max_null(arg, val)`	Finds the row with the maximum `val` and calculates the `arg` expression at that row. Rows where the `val` expression evaluates to `NULL` are ignored. This function is affected by ordering.
`arg_min(arg, val)`	Finds the row with the minimum `val` and calculates the `arg` expression at that row. Rows where the value of the `arg` or `val` expression is `NULL` are ignored. This function is affected by ordering.
`arg_min(arg, val, n)`	Returns a `LIST` containing the `arg` expressions for the ”bottom” n rows ordered by `val` ascending. This function is affected by ordering.
`arg_min_null(arg, val)`	Finds the row with the minimum `val` and calculates the `arg` expression at that row. Rows where the `val` expression evaluates to `NULL` are ignored. This function is affected by ordering.
`avg(arg)`	Calculates the average of all non-null values in `arg`. This function is affected by ordering.
`bit_and(arg)`	Returns the bitwise AND of all bits in a given expression.
`bit_or(arg)`	Returns the bitwise OR of all bits in a given expression.
`bit_xor(arg)`	Returns the bitwise XOR of all bits in a given expression.
`bitstring_agg(arg)`	Returns a bitstring whose length corresponds to the range of the non-null (integer) values, with bits set at the location of each (distinct) value.
`bool_and(arg)`	Returns `true` if every input value is `true`, otherwise `false`.
`bool_or(arg)`	Returns `true` if any input value is `true`, otherwise `false`.
`count()`	Returns the number of rows.
`count(arg)`	Returns the number of rows where `arg` is not `NULL`.
`countif(arg)`	Returns the number of rows where `arg` is `true`.
`favg(arg)`	Calculates the average using a more accurate floating point summation (Kahan Sum). This function is affected by ordering.
`first(arg)`	Returns the first value (null or non-null) from `arg`. This function is affected by ordering.

Function	Description
`fsum(arg)`	Calculates the sum using a more accurate floating point summation (Kahan Sum). This function is affected by ordering.
`geometric_mean(arg)`	Calculates the geometric mean of all non-null values in `arg`. This function is affected by ordering.
`histogram(arg)`	Returns a `MAP` of key-value pairs representing buckets and counts.
`histogram(arg, boundaries)`	Returns a `MAP` of key-value pairs representing the provided upper `boundaries` and counts of elements in the corresponding bins (left-open and right-closed partitions) of the datatype. A boundary at the largest value of the datatype is automatically added when elements larger than all provided `boundaries` appear, see `is_histogram_other_bin`. Boundaries may be provided, e.g., via `equi_width_bins`.
`histogram_exact(arg, elements)`	Returns a `MAP` of key-value pairs representing the requested elements and their counts. A catch-all element specific to the data-type is automatically added to count other elements when they appear, see `is_histogram_other_bin`.
`histogram_values(source, boundaries)`	Returns the upper boundaries of the bins and their counts.
`last(arg)`	Returns the last value of a column. This function is affected by ordering.
`list(arg)`	Returns a `LIST` containing all the values of a column. This function is affected by ordering.
`max(arg)`	Returns the maximum value present in `arg`. This function is unaffected by distinctness.
`max(arg, n)`	Returns a `LIST` containing the `arg` values for the ”top” n rows ordered by `arg` descending.
`min(arg)`	Returns the minimum value present in `arg`. This function is unaffected by distinctness.
`min(arg, n)`	Returns a `LIST` containing the `arg` values for the ”bottom” n rows ordered by `arg` ascending.
`product(arg)`	Calculates the product of all non-null values in `arg`. This function is affected by ordering.
`string_agg(arg)`	Concatenates the column string values with a comma separator (`,`). This function is affected by ordering.
`string_agg(arg, sep)`	Concatenates the column string values with a separator. This function is affected by ordering.
`sum(arg)`	Calculates the sum of all non-null values in `arg` / counts `true` values when `arg` is boolean. The floating-point versions of this function are affected by ordering.
`weighted_avg(arg, weight)`	Calculates the weighted average of all non-null values in `arg`, where each value is scaled by its corresponding `weight`. If `weight` is `NULL`, the corresponding `arg` value will be skipped. This function is affected by ordering.

`any_value(arg)`

Description	Returns the first non-`NULL` value from `arg`. This function is affected by ordering.
Example	`any_value(A)`

`arg_max(arg, val)`

Description	Finds the row with the maximum `val` and calculates the `arg` expression at that row. Rows where the value of the `arg` or `val` expression is `NULL` are ignored. This function is affected by ordering.
Example	`arg_max(A, B)`
Alias(es)	`argmax(arg, val)`,`max_by(arg, val)`

arg_max(arg, val, n)

Description	The generalized case of `arg_max` for n values: returns a `LIST` containing the `arg` expressions for the top n rows ordered by `val` descending. This function is affected by ordering.
Example	`arg_max(A, B, 2)`
Alias(es)	`argmax(arg, val, n)`,`max_by(arg, val, n)`

arg_max_null(arg, val)

Description	Finds the row with the maximum `val` and calculates the `arg` expression at that row. Rows where the `val` expression evaluates to `NULL` are ignored. This function is affected by ordering.
Example	`arg_max_null(A, B)`

arg_min(arg, val)

Description	Finds the row with the minimum `val` and calculates the `arg` expression at that row. Rows where the value of the `arg` or `val` expression is `NULL` are ignored. This function is affected by ordering.
Example	`arg_min(A, B)`
Alias(es)	`argmin(arg, val)`,`min_by(arg, val)`

arg_min(arg, val, n)

Description	The generalized case of `arg_min` for n values: returns a `LIST` containing the `arg` expressions for the bottom n rows ordered by `val` ascending. This function is affected by ordering.
Example	`arg_min(A, B, 2)`
Alias(es)	`argmin(arg, val, n)`,`min_by(arg, val, n)`

arg_min_null(arg, val)

Description	Finds the row with the minimum `val` and calculates the `arg` expression at that row. Rows where the `val` expression evaluates to `NULL` are ignored. This function is affected by ordering.
Example	`arg_min_null(A, B)`

avg(arg)

Description	Calculates the average of all non-null values in `arg`. This function is affected by ordering.
Example	`avg(A)`
Alias(es)	`mean`

bit_and(arg)

Description	Returns the bitwise AND of all bits in a given expression.
Example	`bit_and(A)`

`bit_or(arg)`

Description	Returns the bitwise OR of all bits in a given expression.
Example	`bit_or(A)`

`bit_xor(arg)`

Description	Returns the bitwise XOR of all bits in a given expression.
Example	`bit_xor(A)`

`bitstring_agg(arg)`

Description	Returns a bitstring whose length corresponds to the range of the non-null (integer) values, with bits set at the location of each (distinct) value.
Example	`bitstring_agg(A)`

`bool_and(arg)`

Description	Returns `true` if every input value is `true`, otherwise `false`.
Example	`bool_and(A)`

`bool_or(arg)`

Description	Returns `true` if any input value is `true`, otherwise `false`.
Example	`bool_or(A)`

`count()`

Description	Returns the number of rows.
Example	`count()`
Alias(es)	`count(*)`

`count(arg)`

Description	Returns the number of rows where `arg` is not `NULL`.
Example	`count(A)`

`countif(arg)`

Description	Returns the number of rows where `arg` is `true`.
Example	`countif(A)`

`favg(arg)`

Description	Calculates the average using a more accurate floating point summation (Kahan Sum). This function is affected by ordering.
Example	`favg(A)`

`first(arg)`

Description	Returns the first value (null or non-null) from `arg`. This function is affected by ordering.
Example	`first(A)`
Alias(es)	`arbitrary(A)`

`fsum(arg)`

Description	Calculates the sum using a more accurate floating point summation (Kahan Sum). This function is affected by ordering.
Example	`fsum(A)`
Alias(es)	`sumkahan`, `kahan_sum`

`geometric_mean(arg)`

Description	Calculates the geometric mean of all non-null values in `arg`. This function is affected by ordering.
Example	`geometric_mean(A)`
Alias(es)	`geomean(A)`

`histogram(arg)`

Description	Returns a `MAP` of key-value pairs representing buckets and counts.
Example	`histogram(A)`

`histogram(arg, boundaries)`

Description	Returns a MAP of key-value pairs representing the provided upper `boundaries` and counts of elements in the corresponding bins (left-open and right-closed partitions) of the datatype. A boundary at the largest value of the datatype is automatically added when elements larger than all provided `boundaries` appear, see `is_histogram_other_bin`. Boundaries may be provided, e.g., via `equi_width_bins`.
Example	`histogram(A, [0, 1, 10])`

`histogram_exact(arg, elements)`

Description	Returns a MAP of key-value pairs representing the requested elements and their counts. A catch-all element specific to the data-type is automatically added to count other elements when they appear, see `is_histogram_other_bin`.
Example	`histogram_exact(A, ['a', 'b', 'c'])`

`histogram_values(source, col_name, technique, bin_count)`

Description	Returns the upper boundaries of the bins and their counts.
Example	`histogram_values(integers, i, bin_count := 2)`

`last(arg)`

Description	Returns the last value of a column. This function is affected by ordering.
Example	`last(A)`

`list(arg)`

Description	Returns a `LIST` containing all the values of a column. This function is affected by ordering.
Example	`list(A)`
Alias(es)	`array_agg`

`max(arg)`

Description	Returns the maximum value present in `arg`. This function is unaffected by distinctness.
Example	`max(A)`

`max(arg, n)`

Description	Returns a `LIST` containing the `arg` values for the ”top” n rows ordered by `arg` descending.
Example	`max(A, 2)`

`min(arg)`

Description	Returns the minimum value present in `arg`. This function is unaffected by distinctness.
Example	`min(A)`

`min(arg, n)`

Description	Returns a `LIST` containing the `arg` values for the ”bottom” n rows ordered by `arg` ascending.
Example	`min(A, 2)`

`product(arg)`

Description	Calculates the product of all non-null values in `arg`. This function is affected by ordering.
Example	`product(A)`

`string_agg(arg)`

Description	Concatenates the column string values with a comma separator (`,`). This function is affected by ordering.
Example	`string_agg(S, ',')`
Alias(es)	`group_concat(arg)`,`listagg(arg)`

`string_agg(arg, sep)`

Description	Concatenates the column string values with a separator. This function is affected by ordering.
Example	`string_agg(S, ',')`
Alias(es)	`group_concat(arg, sep)`,`listagg(arg, sep)`

`sum(arg)`

Description	Calculates the sum of all non-null values in `arg` / counts `true` values when `arg` is boolean. The floating-point versions of this function are affected by ordering.
Example	`sum(A)`

`weighted_avg(arg, weight)`

Description	Calculates the weighted average of all non-null values in `arg`, where each value is scaled by its corresponding `weight`. If `weight` is `NULL`, the value will be skipped. This function is affected by ordering.
Example	`weighted_avg(A, W)`
Alias(es)	`wavg(arg, weight)`

Approximate Aggregates

The table below shows the available approximate aggregate functions.

Function	Description	Example
`approx_count_distinct(x)`	Calculates the approximate count of distinct elements using HyperLogLog.	`approx_count_distinct(A)`
`approx_quantile(x, pos)`	Calculates the approximate quantile using T-Digest.	`approx_quantile(A, 0.5)`
`approx_top_k(arg, k)`	Calculates a `LIST` of the `k` approximately most frequent values of `arg` using Filtered Space-Saving.	
`reservoir_quantile(x, quantile, sample_size = 8192)`	Calculates the approximate quantile using reservoir sampling, the sample size is optional and uses 8192 as a default size.	`reservoir_quantile(A, 0.5, 1024)`

Statistical Aggregates

The table below shows the available statistical aggregate functions. They all ignore `NULL` values (in the case of a single input column `x`), or pairs where either input is `NULL` (in the case of two input columns `y` and `x`).

Function	Description
`corr(y, x)`	The correlation coefficient.
`covar_pop(y, x)`	The population covariance, which does not include bias correction.
`covar_samp(y, x)`	The sample covariance, which includes Bessel's bias correction.
`entropy(x)`	The log-2 entropy of count input-values.
`kurtosis_pop(x)`	The excess kurtosis (Fisher's definition) without bias correction.
`kurtosis(x)`	The excess kurtosis (Fisher's definition) with bias correction according to the sample size.
`mad(x)`	The median absolute deviation. Temporal types return a positive `INTERVAL`.
`median(x)`	The middle value of the set. For even value counts, quantitative values are averaged and ordinal values return the lower value.
`mode(x)`	The most frequent value. This function is affected by ordering.
`quantile_cont(x, pos)`	The interpolated `pos`-quantile of `x` for `-1 <= pos <= 1`. Returns the `pos * (n_nonnull_values - 1)`th (zero-indexed, in the specified order) value of `x` or an interpolation between the adjacent values if the index is not an integer. Values of `pos` between `-1` and `0` correspond to counting backwards from `1`. More precisely, `quantile_cont(x, -y) = quantile_cont(x, 1 - y)`. Intuitively, arranges the values of `x` as equispaced *points* on a line, starting at 0 and ending at 1, and returns the (interpolated) value at `pos`. This is Type 7 in Hyndman & Fan (1996). If `pos` is a `LIST` of `FLOAT`s, then the result is a `LIST` of the corresponding interpolated quantiles.
`quantile_disc(x, pos)`	The discrete `pos`-quantile of `x` for `0 <= pos <= 1`. Returns the `greatest(ceil(pos * n_nonnull_values) - 1, 0)`th (zero-indexed, in the specified order) value of `x`. Intuitively, assigns to each value of `x` an equisized *sub-interval* (left-open and right-closed except for the initial interval) of the interval `[0, 1]`, and picks the value of the sub-interval that contains `pos`. This is Type 1 in Hyndman & Fan (1996). If `pos` is a `LIST` of `FLOAT`s, then the result is a `LIST` of the corresponding discrete quantiles.

Function	Description
`regr_avgx(y, x)`	The average of the independent variable for non-NULL pairs, where x is the independent variable and y is the dependent variable.
`regr_avgy(y, x)`	The average of the dependent variable for non-NULL pairs, where x is the independent variable and y is the dependent variable.
`regr_count(y, x)`	The number of non-NULL pairs.
`regr_intercept(y, x)`	The intercept of the univariate linear regression line, where x is the independent variable and y is the dependent variable.
`regr_r2(y, x)`	The squared Pearson correlation coefficient between y and x. Also: The coefficient of determination in a linear regression, where x is the independent variable and y is the dependent variable.
`regr_slope(y, x)`	The slope of the linear regression line, where x is the independent variable and y is the dependent variable.
`regr_sxx(y, x)`	The sample variance, which includes Bessel's bias correction, of the independent variable for non-NULL pairs, where x is the independent variable and y is the dependent variable.
`regr_sxy(y, x)`	The sample covariance, which includes Bessel's bias correction.
`regr_syy(y, x)`	The sample variance, which includes Bessel's bias correction, of the dependent variable for non-NULL pairs, where x is the independent variable and y is the dependent variable.
`skewness(x)`	The skewness.
`sem(x)`	The standard error of the mean.
`stddev_pop(x)`	The population standard deviation.
`stddev_samp(x)`	The sample standard deviation.
`var_pop(x)`	The population variance, which does not include bias correction.
`var_samp(x)`	The sample variance, which includes Bessel's bias correction.

`corr(y, x)`

Description	The correlation coefficient.
Formula	`covar_pop(y, x) / (stddev_pop(x) * stddev_pop(y))`

`covar_pop(y, x)`

Description	The population covariance, which does not include bias correction.
Formula	`(sum(x*y) - sum(x) * sum(y) / regr_count(y, x)) / regr_count(y, x)`, `covar_samp(y, x) * (1 - 1 / regr_count(y, x))`

`covar_samp(y, x)`

Description	The sample covariance, which includes Bessel's bias correction.
Formula	`(sum(x*y) - sum(x) * sum(y) / regr_count(y, x)) / (regr_count(y, x) - 1)`,`covar_pop(y, x) / (1 - 1 / regr_count(y, x))`
Alias(es)	`regr_sxy(y, x)`

`entropy(x)`

Description	The log-2 entropy of count input-values.
Formula	-

`kurtosis_pop(x)`

Description	The excess kurtosis (Fisher's definition) without bias correction.
Formula	-

`kurtosis(x)`

Description	The excess kurtosis (Fisher's definition) with bias correction according to the sample size.
Formula	-

`mad(x)`

Description	The median absolute deviation. Temporal types return a positive `INTERVAL`.
Formula	`median(abs(x - median(x)))`

`median(x)`

Description	The middle value of the set. For even value counts, quantitative values are averaged and ordinal values return the lower value.
Formula	`quantile_cont(x, 0.5)`

`mode(x)`

Description	The most frequent value. This function is affected by ordering.
Formula	-

`quantile_cont(x, pos)`

Description	The interpolated `pos`-quantile of `x` for `0 <= pos <= 1`. Returns the `pos * (n_nonnull_values - 1)`th (zero-indexed, in the specified order) value of `x` or an interpolation between the adjacent values if the index is not an integer. Intuitively, arranges the values of `x` as equispaced *points* on a line, starting at 0 and ending at 1, and returns the (interpolated) value at `pos`. This is Type 7 in Hyndman & Fan (1996). If `pos` is a `LIST` of `FLOAT`s, then the result is a `LIST` of the corresponding interpolated quantiles.
Formula	-

`quantile_disc(x, pos)`

Description	The discrete `pos`-quantile of `x` for `0 <= pos <= 1`. Returns the `greatest(ceil(pos * n_nonnull_values) - 1, 0)`th (zero-indexed, in the specified order) value of `x`. Intuitively, assigns to each value of `x` an equisized *sub-interval* (left-open and right-closed except for the initial interval) of the interval `[0, 1]`, and picks the value of the sub-interval that contains `pos`. This is Type 1 in Hyndman & Fan (1996). If `pos` is a `LIST` of `FLOAT`s, then the result is a `LIST` of the corresponding discrete quantiles.
Formula	-
Alias(es)	`quantile`

`regr_avgx(y, x)`

Description	The average of the independent variable for non-`NULL` pairs, where x is the independent variable and y is the dependent variable.
Formula	-

`regr_avgy(y, x)`

Description	The average of the dependent variable for non-`NULL` pairs, where x is the independent variable and y is the dependent variable.
Formula	-

`regr_count(y, x)`

Description	The number of non-`NULL` pairs.
Formula	-

`regr_intercept(y, x)`

Description	The intercept of the univariate linear regression line, where x is the independent variable and y is the dependent variable.
Formula	`regr_avgy(y, x) - regr_slope(y, x) * regr_avgx(y, x)`

`regr_r2(y, x)`

Description	The squared Pearson correlation coefficient between y and x. Also: The coefficient of determination in a linear regression, where x is the independent variable and y is the dependent variable.
Formula	-

`regr_slope(y, x)`

Description	Returns the slope of the linear regression line, where x is the independent variable and y is the dependent variable.
Formula	`regr_sxy(y, x) / regr_sxx(y, x)`
Alias(es)	-

`regr_sxx(y, x)`

Description	The sample variance, which includes Bessel's bias correction, of the independent variable for non-NULL pairs, where x is the independent variable and y is the dependent variable.
Formula	-

`regr_sxy(y, x)`

Description	The sample covariance, which includes Bessel's bias correction.
Formula	`(sum(x*y) - sum(x) * sum(y) / regr_count(y, x)) / (regr_count(y, x) - 1),covar_pop(y, x) / (1 - 1 / regr_count(y, x))`
Alias(es)	`covar_samp(y, x)`

`regr_syy(y, x)`

Description	The sample variance, which includes Bessel's bias correction, of the dependent variable for non-NULL pairs, where x is the independent variable and y is the dependent variable.
Formula	-

`sem(x)`

Description	The standard error of the mean.
Formula	-

`skewness(x)`

Description	The skewness.
Formula	-

`stddev_pop(x)`

Description	The population standard deviation.
Formula	`sqrt(var_pop(x))`

`stddev_samp(x)`

Description	The sample standard deviation.
Formula	`sqrt(var_samp(x))`
Alias(es)	`stddev(x)`

`var_pop(x)`

Description	The population variance, which does not include bias correction.
Formula	`(sum(x^2) - sum(x)^2 / count(x)) / count(x),var_samp(y, x) * (1 - 1 / count(x))`

`var_samp(x)`

Description	The sample variance, which includes Bessel's bias correction.
Formula	`(sum(x^2) - sum(x)^2 / count(x)) / (count(x) - 1),var_pop(y, x) / (1 - 1 / count(x))`
Alias(es)	`variance(arg, val)`

Ordered Set Aggregate Functions

The table below shows the available "ordered set" aggregate functions. These functions are specified using the `WITHIN GROUP (ORDER BY sort_expression)` syntax, and they are converted to an equivalent aggregate function that takes the ordering expression as the first argument.

Function	Equivalent
mode() WITHIN GROUP (ORDER BY column [(ASC|DESC)])	mode(column ORDER BY column [(ASC|DESC)])
percentile_cont(fraction) WITHIN GROUP (ORDER BY column [(ASC|DESC)])	quantile_cont(column, fraction ORDER BY column [(ASC|DESC)])
percentile_cont(fractions) WITHIN GROUP (ORDER BY column [(ASC|DESC)])	quantile_cont(column, fractions ORDER BY column [(ASC|DESC)])
percentile_disc(fraction) WITHIN GROUP (ORDER BY column [(ASC|DESC)])	quantile_disc(column, fraction ORDER BY column [(ASC|DESC)])
percentile_disc(fractions) WITHIN GROUP (ORDER BY column [(ASC|DESC)])	quantile_disc(column, fractions ORDER BY column [(ASC|DESC)])

Miscellaneous Aggregate Functions

Function	Description	Alias
`grouping()`	For queries with GROUP BY and either ROLLUP or GROUPING SETS: Returns an integer identifying which of the argument expressions were used to group on to create the current super-aggregate row.	`grouping_id()`

Array Functions

All LIST functions work with the ARRAY data type. Additionally, several ARRAY-native functions are also supported.

Array-Native Functions

Function	Description
`array_cosine_distance(array1, array2)`	Computes the cosine distance between two arrays of the same size. The array elements cannot be NULL. The arrays can have any size as long as the size is the same for both arguments.
`array_cosine_similarity(array1, array2)`	Computes the cosine similarity between two arrays of the same size. The array elements cannot be NULL. The arrays can have any size as long as the size is the same for both arguments.
`array_cross_product(array, array)`	Computes the cross product of two arrays of size 3. The array elements cannot be NULL.
`array_distance(array1, array2)`	Computes the distance between two arrays of the same size. The array elements cannot be NULL. The arrays can have any size as long as the size is the same for both arguments.
`array_dot_product(array1, array2)`	Alias for `array_inner_product`.
`array_inner_product(array1, array2)`	Computes the inner product between two arrays of the same size. The array elements cannot be NULL. The arrays can have any size as long as the size is the same for both arguments.
`array_negative_dot_product(array1, array2)`	Alias for `array_negative_inner_product`.
`array_negative_inner_product(array1, array2)`	Computes the negative inner product between two arrays of the same size. The array elements cannot be NULL. The arrays can have any size as long as the size is the same for both arguments.
`array_value(arg, ...)`	Creates an ARRAY containing the argument values.

`array_cosine_distance(array1, array2)`

Description	Computes the cosine distance between two arrays of the same size. The array elements cannot be NULL. The arrays can have any size as long as the size is the same for both arguments.
Example	`array_cosine_distance(array_value(1.0::FLOAT, 2.0::FLOAT, 3.0::FLOAT), array_value(2.0::FLOAT, 3.0::FLOAT, 4.0::FLOAT))`
Result	`0.007416606`

`array_cosine_similarity(array1, array2)`

Description	Computes the cosine similarity between two arrays of the same size. The array elements cannot be NULL. The arrays can have any size as long as the size is the same for both arguments.
Example	`array_cosine_similarity(array_value(1.0::FLOAT, 2.0::FLOAT, 3.0::FLOAT), array_value(2.0::FLOAT, 3.0::FLOAT, 4.0::FLOAT))`
Result	`0.9925834`

`array_cross_product(array, array)`

Description	Computes the cross product of two arrays of size 3. The array elements cannot be NULL.
Example	`array_cross_product(array_value(1.0::FLOAT, 2.0::FLOAT, 3.0::FLOAT), array_value(2.0::FLOAT, 3.0::FLOAT, 4.0::FLOAT))`
Result	`[-1.0, 2.0, -1.0]`

`array_distance(array1, array2)`

Description	Computes the distance between two arrays of the same size. The array elements cannot be NULL. The arrays can have any size as long as the size is the same for both arguments.
Example	`array_distance(array_value(1.0::FLOAT, 2.0::FLOAT, 3.0::FLOAT), array_value(2.0::FLOAT, 3.0::FLOAT, 4.0::FLOAT))`
Result	`1.7320508`

`array_inner_product(array1, array2)`

Description	Computes the inner product between two arrays of the same size. The array elements cannot be NULL. The arrays can have any size as long as the size is the same for both arguments.
Example	`array_inner_product(array_value(1.0::FLOAT, 2.0::FLOAT, 3.0::FLOAT), array_value(2.0::FLOAT, 3.0::FLOAT, 4.0::FLOAT))`
Result	`20.0`
Alias	`array_dot_product`

`array_negative_inner_product(array1, array2)`

Description	Computes the negative inner product between two arrays of the same size. The array elements cannot be NULL. The arrays can have any size as long as the size is the same for both arguments.
Example	`array_negative_inner_product(array_value(1.0::FLOAT, 2.0::FLOAT, 3.0::FLOAT), array_value(2.0::FLOAT, 3.0::FLOAT, 4.0::FLOAT))`
Result	`-20.0`
Alias	`array_negative_dot_product`

`array_value(arg, ...)`

Description	Creates an ARRAY containing the argument values.
Example	`array_value(1.0::FLOAT, 2.0::FLOAT, 3.0::FLOAT)`
Result	`[1.0, 2.0, 3.0]`

Bitstring Functions

This section describes functions and operators for examining and manipulating `BITSTRING` values. Bitstrings must be of equal length when performing the bitwise operands AND, OR and XOR. When bit shifting, the original length of the string is preserved.

Bitstring Operators

The table below shows the available mathematical operators for `BIT` type.

Operator	Description	Example	Result
`&`	Bitwise AND	`'10101'::BITSTRING & '10001'::BITSTRING`	`10001`
`|`	Bitwise OR	`'1011'::BITSTRING | '0001'::BITSTRING`	`1011`
`xor`	Bitwise XOR	`xor('101'::BITSTRING, '001'::BITSTRING)`	`100`
`~`	Bitwise NOT	`~('101'::BITSTRING)`	`010`
`<<`	Bitwise shift left	`'1001011'::BITSTRING << 3`	`1011000`
`>>`	Bitwise shift right	`'1001011'::BITSTRING >> 3`	`0001001`

Bitstring Functions

The table below shows the available scalar functions for `BIT` type.

Name	Description
`bit_count(bitstring)`	Returns the number of set bits in the bitstring.
`bit_length(bitstring)`	Returns the number of bits in the bitstring.
`bit_position(substring, bitstring)`	Returns first starting index of the specified substring within bits, or zero if it's not present. The first (leftmost) bit is indexed 1.
`bitstring(bitstring, length)`	Returns a bitstring of determined length.
`get_bit(bitstring, index)`	Extracts the nth bit from bitstring; the first (leftmost) bit is indexed 0.
`length(bitstring)`	Alias for `bit_length`.
`octet_length(bitstring)`	Returns the number of bytes in the bitstring.
`set_bit(bitstring, index, new_value)`	Sets the nth bit in bitstring to newvalue; the first (leftmost) bit is indexed 0. Returns a new bitstring.

`bit_count(bitstring)`

Description	Returns the number of set bits in the bitstring.
Example	`bit_count('1101011'::BITSTRING)`
Result	5

`bit_length(bitstring)`

Description	Returns the number of bits in the bitstring.
Example	`bit_length('1101011'::BITSTRING)`
Result	7

`bit_position(substring, bitstring)`

Description	Returns first starting index of the specified substring within bits, or zero if it's not present. The first (leftmost) bit is indexed 1
Example	`bit_position('010'::BITSTRING, '1110101'::BITSTRING)`
Result	4

`bitstring(bitstring, length)`

Description	Returns a bitstring of determined length.
Example	`bitstring('1010'::BITSTRING, 7)`
Result	`0001010`

`get_bit(bitstring, index)`

Description	Extracts the nth bit from bitstring; the first (leftmost) bit is indexed 0.
Example	`get_bit('0110010'::BITSTRING, 2)`
Result	1

`length(bitstring)`

Description	Alias for `bit_length`.
Example	`length('1101011'::BITSTRING)`
Result	7

`octet_length(bitstring)`

Description	Returns the number of bytes in the bitstring.
Example	`octet_length('1101011'::BITSTRING)`
Result	`1`

`set_bit(bitstring, index, new_value)`

Description	Sets the nth bit in bitstring to newvalue; the first (leftmost) bit is indexed `0`. Returns a new bitstring.
Example	`set_bit('0110010'::BITSTRING, 2, 0)`
Result	`0100010`

Bitstring Aggregate Functions

These aggregate functions are available for `BIT` type.

Name	Description
`bit_and(arg)`	Returns the bitwise AND operation performed on all bitstrings in a given expression.
`bit_or(arg)`	Returns the bitwise OR operation performed on all bitstrings in a given expression.
`bit_xor(arg)`	Returns the bitwise XOR operation performed on all bitstrings in a given expression.
`bitstring_agg(arg)`	Returns a bitstring with bits set for each distinct position defined in `arg`.
`bitstring_agg(arg, min, max)`	Returns a bitstring with bits set for each distinct position defined in `arg`. All positions must be within the range [`min`, `max`] or an `Out of Range Error` will be thrown.

`bit_and(arg)`

Description	Returns the bitwise AND operation performed on all bitstrings in a given expression.
Example	`bit_and(A)`

`bit_or(arg)`

Description	Returns the bitwise OR operation performed on all bitstrings in a given expression.
Example	`bit_or(A)`

`bit_xor(arg)`

Description	Returns the bitwise XOR operation performed on all bitstrings in a given expression.
Example	`bit_xor(A)`

`bitstring_agg(arg)`

Description	The `bitstring_agg` function takes any integer type as input and returns a bitstring with bits set for each distinct value. The left-most bit represents the smallest value in the column and the right-most bit the maximum value. If possible, the min and max are retrieved from the column statistics. Otherwise, it is also possible to provide the min and max values.
Example	`bitstring_agg(A)`

> **Tip.** The combination of `bit_count` and `bitstring_agg` can be used as an alternative to `count(DISTINCT ...)`, with possible performance improvements in cases of low cardinality and dense values.

`bitstring_agg(arg, min, max)`

Description	Returns a bitstring with bits set for each distinct position defined in `arg`. All positions must be within the range [`min`, `max`] or an `Out of Range Error` will be thrown.
Example	`bitstring_agg(A, 1, 42)`

Blob Functions

This section describes functions and operators for examining and manipulating BLOB values.

Function	Description
`arg1 || arg2`	Concatenates two strings, lists, or blobs. Any `NULL` input results in `NULL`. See also `concat(arg1, arg2, ...)` and `list_concat(list1, list2, ...)`.
`base64(blob)`	Alias for `to_base64`.
`decode(blob[, on_error])`	Converts `blob` to VARCHAR. The optional `on_error` parameter controls handling of invalid UTF-8: `'strict'` (default, throws error), `'replace'` (replaces invalid characters with ?), or `'ignore'` (removes invalid characters).
`encode(string)`	Converts the `string` to BLOB. Converts UTF-8 characters into literal encoding.
`from_base64(string)`	Converts a base64 encoded `string` to a character string (BLOB).
`from_binary(value)`	Alias for `unbin`.
`from_hex(value)`	Alias for `unhex`.
`hex(blob)`	Converts `blob` to VARCHAR using hexadecimal encoding.
`md5(blob)`	Returns the MD5 hash of the `blob` as a VARCHAR.
`md5_number(blob)`	Returns the MD5 hash of the `blob` as a HUGEINT.
`octet_length(blob)`	Number of bytes in `blob`.
`read_blob(source)`	Returns the content from `source` (a filename, a list of filenames, or a glob pattern) as a BLOB. See the `read_blob` guide for more details.
`repeat(blob, count)`	Repeats the `blob` `count` number of times.
`sha1(blob)`	Returns a VARCHAR with the SHA-1 hash of the `blob`.
`sha256(blob)`	Returns a VARCHAR with the SHA-256 hash of the `blob`.
`to_base64(blob)`	Converts a `blob` to a base64 encoded string.
`to_hex(blob)`	Alias for `hex`.

Function	Description
`unbin(value)`	Converts a `value` from binary representation to a blob.
`unhex(value)`	Converts a `value` from hexadecimal representation to a blob.

`arg1 || arg2`

Description	Concatenates two strings, lists, or blobs. Any `NULL` input results in `NULL`. See also `concat(arg1, arg2, ...)` and `list_concat(list1, list2, ...)`.
Example 1	`'Duck' || 'DB'`
Result	DuckDB
Example 2	`[1, 2, 3] || [4, 5, 6]`
Result	`[1, 2, 3, 4, 5, 6]`
Example 3	`'\xAA'::BLOB || '\xBB'::BLOB`
Result	\xAA\xBB

`decode(blob[, on_error])`

Description	Converts `blob` to VARCHAR. The optional `on_error` parameter controls handling of invalid UTF-8: `'strict'` (default, throws error), `'replace'` (replaces invalid characters with ?), or `'ignore'` (removes invalid characters).
Example	`decode('\xC3\xBC'::BLOB)`
Result	ü
Example	`decode('\xAA'::BLOB, 'replace')`
Result	?

`encode(string)`

Description	Converts the `string` to BLOB. Converts UTF-8 characters into literal encoding.
Example	`encode('my_string_with_ü')`
Result	`my_string_with_\xC3\xBC`

`from_base64(string)`

Description	Converts a base64 encoded `string` to a character string (BLOB).
Example	`from_base64('QQ==')`
Result	A

`hex(blob)`

Description	Converts `blob` to VARCHAR using hexadecimal encoding.

Example	`hex('\xAA\xBB'::BLOB)`
Result	AABB
Alias	`to_hex`

`md5(blob)`

Description	Returns the MD5 hash of the `blob` as a VARCHAR.
Example	`md5('\xAA\xBB'::BLOB)`
Result	`58cea1f6b2b06520613e09af90dc1c47`

`md5_number(blob)`

Description	Returns the MD5 hash of the `blob` as a HUGEINT.
Example	`md5_number('\xAA\xBB'::BLOB)`
Result	`94525045605907259200829535064523132504`

`octet_length(blob)`

Description	Number of bytes in `blob`.
Example	`octet_length('\xAA\xBB'::BLOB)`
Result	2

`read_blob(source)`

Description	Returns the content from `source` (a filename, a list of filenames, or a glob pattern) as a BLOB. See the `read_blob` guide for more details.
Example	`read_blob('hello.bin')`
Result	`hello\x0A`

`repeat(blob, count)`

Description	Repeats the `blob` `count` number of times.
Example	`repeat('\xAA\xBB'::BLOB, 5)`
Result	`\xAA\xBB\xAA\xBB\xAA\xBB\xAA\xBB\xAA\xBB`

`sha1(blob)`

Description	Returns a VARCHAR with the SHA-1 hash of the `blob`.
Example	`sha1('\xAA\xBB'::BLOB)`

Result	`65b1e351a6cbfeb41c927222bc9ef53aad3396b0`

`sha256(blob)`

Description	Returns a VARCHAR with the SHA-256 hash of the `blob`.
Example	`sha256('\xAA\xBB'::BLOB)`
Result	`d798d1fac6bd4bb1c11f50312760351013379a0ab6f0a8c0af8a506b96b2525a`

`to_base64(blob)`

Description	Converts a `blob` to a base64 encoded string.
Example	`to_base64('A'::BLOB)`
Result	`QQ==`
Alias	`base64`

`unbin(value)`

Description	Converts a `value` from binary representation to a blob.
Example	`unbin('0110')`
Result	`\x06`
Alias	`from_binary`

`unhex(value)`

Description	Converts a `value` from hexadecimal representation to a blob.
Example	`unhex('2A')`
Result	`*`
Alias	`from_hex`

Date Format Functions

The `strftime` and `strptime` functions can be used to convert between `DATE` / `TIMESTAMP` values and strings. This is often required when parsing CSV files, displaying output to the user or transferring information between programs. Because there are many possible date representations, these functions accept a format string that describes how the date or timestamp should be structured.

`strftime` Examples

The `strftime(timestamp, format)` converts timestamps or dates to strings according to the specified pattern.

```
SELECT strftime(DATE '1992-03-02', '%d/%m/%Y');
```

```
02/03/1992
```

```
SELECT strftime(TIMESTAMP '1992-03-02 20:32:45', '%A, %-d %B %Y - %I:%M:%S %p');
```

```
Monday, 2 March 1992 - 08:32:45 PM
```

`strptime` Examples

The `strptime(text, format)` function converts strings to timestamps according to the specified pattern.

```
SELECT strptime('02/03/1992', '%d/%m/%Y');
```

```
1992-03-02 00:00:00
```

```
SELECT strptime('Monday, 2 March 1992 - 08:32:45 PM', '%A, %-d %B %Y - %I:%M:%S %p');
```

```
1992-03-02 20:32:45
```

The `strptime` function throws an error on failure:

```
SELECT strptime('02/50/1992', '%d/%m/%Y') AS x;
```

```
Invalid Input Error:
Could not parse string "02/50/1992" according to format specifier "%d/%m/%Y"
02/50/1992
   ^
Error: Month out of range, expected a value between 1 and 12
```

To return `NULL` on failure, use the `try_strptime` function:

```
NULL
```

CSV Parsing

The date formats can also be specified during CSV parsing, either in the COPY statement or in the `read_csv` function. This can be done by either specifying a `DATEFORMAT` or a `TIMESTAMPFORMAT` (or both). `DATEFORMAT` will be used for converting dates, and `TIMESTAMPFORMAT` will be used for converting timestamps. Below are some examples for how to use this.

In a COPY statement:

```
COPY dates FROM 'test.csv' (DATEFORMAT '%d/%m/%Y', TIMESTAMPFORMAT '%A, %-d %B %Y - %I:%M:%S %p');
```

In a `read_csv` function:

```
SELECT *
FROM read_csv('test.csv', dateformat = '%m/%d/%Y', timestampformat = '%A, %-d %B %Y - %I:%M:%S %p');
```

Format Specifiers

Below is a full list of all available format specifiers.

Specifier	Description	Example
%a	Abbreviated weekday name.	Sun, Mon, ...
%A	Full weekday name.	Sunday, Monday, ...
%b	Abbreviated month name.	Jan, Feb, ..., Dec
%B	Full month name.	January, February, ...
%c	ISO date and time representation	1992-03-02 10:30:20
%d	Day of the month as a zero-padded decimal.	01, 02, ..., 31

Specifier	Description	Example
%-d	Day of the month as a decimal number.	1, 2, ..., 30
%f	Microsecond as a decimal number, zero-padded on the left.	000000 - 999999
%g	Millisecond as a decimal number, zero-padded on the left.	000 - 999
%G	ISO 8601 year with century representing the year that contains the greater part of the ISO week (see %V).	0001, 0002, ..., 2013, 2014, ..., 9998, 9999
%H	Hour (24-hour clock) as a zero-padded decimal number.	00, 01, ..., 23
%-H	Hour (24-hour clock) as a decimal number.	0, 1, ..., 23
%I	Hour (12-hour clock) as a zero-padded decimal number.	01, 02, ..., 12
%-I	Hour (12-hour clock) as a decimal number.	1, 2, ... 12
%j	Day of the year as a zero-padded decimal number.	001, 002, ..., 366
%-j	Day of the year as a decimal number.	1, 2, ..., 366
%m	Month as a zero-padded decimal number.	01, 02, ..., 12
%-m	Month as a decimal number.	1, 2, ..., 12
%M	Minute as a zero-padded decimal number.	00, 01, ..., 59
%-M	Minute as a decimal number.	0, 1, ..., 59
%n	Nanosecond as a decimal number, zero-padded on the left.	000000000 - 999999999
%p	Locale's AM or PM.	AM, PM
%S	Second as a zero-padded decimal number.	00, 01, ..., 59
%-S	Second as a decimal number.	0, 1, ..., 59
%u	ISO 8601 weekday as a decimal number where 1 is Monday.	1, 2, ..., 7
%U	Week number of the year. Week 01 starts on the first Sunday of the year, so there can be week 00. Note that this is not compliant with the week date standard in ISO 8601.	00, 01, ..., 53
%V	ISO 8601 week as a decimal number with Monday as the first day of the week. Week 01 is the week containing Jan 4. Note that %V is incompatible with year directive %Y. Use the ISO year %G instead.	01, ..., 53
%w	Weekday as a decimal number.	0, 1, ..., 6
%W	Week number of the year. Week 01 starts on the first Monday of the year, so there can be week 00. Note that this is not compliant with the week date standard in ISO 8601.	00, 01, ..., 53
%x	ISO date representation	1992-03-02
%X	ISO time representation	10:30:20
%y	Year without century as a zero-padded decimal number. Numbers 00 to 68 are turned into 2000 to 2068. Numbers 69 to 99 are turned into 1969 to 1999.	00, 01, ..., 99
%-y	Year without century as a decimal number. Numbers 0 to 68 are turned into 2000 to 2068. Numbers 69 to 99 are turned into 1969 to 1999.	0, 1, ..., 99
%Y	Year with century as a decimal number.	2013, 2019 etc.
%z	Time offset from UTC in the form ±HH:MM, ±HHMM, or ±HH.	-0700
%Z	Time zone name.	Europe/Amsterdam
%%	A literal % character.	%

Date Functions

This section describes functions and operators for examining and manipulating DATE values.

Date Operators

The table below shows the available mathematical operators for DATE types.

Operator	Description	Example	Result
+	addition of days (integers)	`DATE '1992-03-22' + 5`{:.language-sql .highlight}	`1992-03-27`
+	addition of AN `INTERVAL`	`DATE '1992-03-22' + INTERVAL 5 DAY`{:.language-sql .highlight}	`1992-03-27 00:00:00`
+	addition of a variable `INTERVAL`	`SELECT DATE '1992-03-22' + INTERVAL (d.days) DAY FROM (VALUES (5), (11)) d(days)`{:.language-sql .highlight}	`1992-03-27 00:00:00` and `1992-04-02 00:00:00`
-	subtraction of DATEs	`DATE '1992-03-27' - DATE '1992-03-22'`{:.language-sql .highlight}	`5`
-	subtraction of an `INTERVAL`	`DATE '1992-03-27' - INTERVAL 5 DAY`{:.language-sql .highlight}	`1992-03-22 00:00:00`
-	subtraction of a variable `INTERVAL`	`SELECT DATE '1992-03-27' - INTERVAL (d.days) DAY FROM (VALUES (5), (11)) d(days)`{:.language-sql .highlight}	`1992-03-22 00:00:00` and `1992-03-16 00:00:00`

Adding to or subtracting from infinite values produces the same infinite value.

Date Functions

The table below shows the available functions for DATE types. Dates can also be manipulated with the timestamp functions through type promotion.

Name	Description
`date_add(date, interval)`	Add the interval to the date and return a `DATETIME` value.
`date_diff(part, startdate, enddate)`	The number of `part` boundaries between `startdate` and `enddate`, inclusive of the larger date and exclusive of the smaller date.
`date_part(part, date)`	Get subfield (equivalent to `extract`).
`date_sub(part, startdate, enddate)`	The signed length of the interval between `startdate` and `enddate`, truncated to whole multiples of `part`.
`date_trunc(part, date)`	Truncate to specified precision.
`dayname(date)`	The (English) name of the weekday.
`days_in_month(date)`	The number of days in the month of the given date.
`extract(part from date)`	Get subfield from a date.
`greatest(date, date)`	The later of two dates.

Name	Description
`isfinite(date)`	Returns true if the date is finite, false otherwise.
`isinf(date)`	Returns true if the date is infinite, false otherwise.
`julian(date)`	Extract the Julian Day number from a date.
`last_day(date)`	The last day of the corresponding month in the date.
`least(date, date)`	The earlier of two dates.
`make_date(year, month, day)`	The date for the given parts.
`monthname(date)`	The (English) name of the month.
`strftime(date, format)`	Converts a date to a string according to the format string.
`time_bucket(bucket_width, date[, offset])`	Truncate `date` to a grid of width `bucket_width`. The grid is anchored at `2000-01-01[ + offset]` when `bucket_width` is a number of months or coarser units, else `2000-01-03[ + offset]`. Note that `2000-01-03` is a Monday.
`time_bucket(bucket_width, date[, origin])`	Truncate `timestamptz` to a grid of width `bucket_width`. The grid is anchored at the `origin` timestamp, which defaults to `2000-01-01` when `bucket_width` is a number of months or coarser units, else `2000-01-03`. Note that `2000-01-03` is a Monday.
`today()`	Current date (start of current transaction) in the local time zone.

`date_add(date, interval)`

Description	Add the interval to the date and return a `DATETIME` value.
Example	`date_add(DATE '1992-09-15', INTERVAL 2 MONTH)`
Result	`1992-11-15 00:00:00`

`date_diff(part, startdate, enddate)`

Description	The number of `part` boundaries between `startdate` and `enddate`, inclusive of the larger date and exclusive of the smaller date.
Example	`date_diff('month', DATE '1992-09-15', DATE '1992-11-14')`
Result	2
Alias	`datediff`

`date_part(part, date)`

Description	Get the subfield (equivalent to `extract`).
Example	`date_part('year', DATE '1992-09-20')`
Result	1992
Alias	`datepart`

`date_sub(part, startdate, enddate)`

Description	The signed length of the interval between `startdate` and `enddate`, truncated to whole multiples of `part`.
Example	`date_sub('month', DATE '1992-09-15', DATE '1992-11-14')`
Result	`1`
Alias	`datesub`

`date_trunc(part, date)`

Description	Truncate to specified precision. Always returns a `TIMESTAMP`, even when the input is a `DATE`.
Example	`date_trunc('month', DATE '1992-03-07')`
Result	`1992-03-01 00:00:00`
Alias	`datetrunc`

`dayname(date)`

Description	The (English) name of the weekday.
Example	`dayname(DATE '1992-09-20')`
Result	Sunday

`days_in_month(date)`

Description	The number of days in the month of the given date.
Example	`days_in_month(DATE '1992-02-15')`
Result	`29`

`extract(part from date)`

Description	Get subfield from a date.
Example	`extract('year' FROM DATE '1992-09-20')`
Result	`1992`

`greatest(date, date)`

Description	The later of two dates.
Example	`greatest(DATE '1992-09-20', DATE '1992-03-07')`
Result	`1992-09-20`

`isfinite(date)`

Description	Returns `true` if the date is finite, false otherwise.
Example	`isfinite(DATE '1992-03-07')`
Result	`true`

`isinf(date)`

Description	Returns `true` if the date is infinite, false otherwise.
Example	`isinf(DATE '-infinity')`
Result	`true`

`julian(date)`

Description	Extract the Julian Day number from a date.
Example	`julian(DATE '1992-09-20')`
Result	`2448886.0`

`last_day(date)`

Description	The last day of the corresponding month in the date.
Example	`last_day(DATE '1992-09-20')`
Result	`1992-09-30`

`least(date, date)`

Description	The earlier of two dates.
Example	`least(DATE '1992-09-20', DATE '1992-03-07')`
Result	`1992-03-07`

`make_date(year, month, day)`

Description	The date for the given parts.
Example	`make_date(1992, 9, 20)`
Result	`1992-09-20`

`monthname(date)`

Description	The (English) name of the month.
Example	`monthname(DATE '1992-09-20')`
Result	`September`

`strftime(date, format)`

Description	Converts a date to a string according to the format string.
Example	`strftime(DATE '1992-01-01', '%a, %-d %B %Y')`
Result	`Wed, 1 January 1992`

`time_bucket(bucket_width, date[, offset])`

Description	Truncate `date` to a grid of width `bucket_width`. The grid is anchored at `2000-01-01[ + offset]` when `bucket_width` is a number of months or coarser units, else `2000-01-03[ + offset]`. Note that `2000-01-03` is a Monday.
Example	`time_bucket(INTERVAL '2 months', DATE '1992-04-20', INTERVAL '1 month')`
Result	`1992-04-01`

`time_bucket(bucket_width, date[, origin])`

Description	Truncate `timestamptz` to a grid of width `bucket_width`. The grid is anchored at the `origin` timestamp, which defaults to `2000-01-01` when `bucket_width` is a number of months or coarser units, else `2000-01-03`. Note that `2000-01-03` is a Monday.
Example	`time_bucket(INTERVAL '2 weeks', DATE '1992-04-20', DATE '1992-04-01')`
Result	`1992-04-15`

`today()`

Description	Current date (start of current transaction) in the local time zone.
Example	`today()`
Result	`2022-10-08`
Alias	`current_date` (no parentheses necessary)

Date Part Extraction Functions

There are also dedicated extraction functions to get the subfields. A few examples include extracting the day from a date, or the day of the week from a date.

Functions applied to infinite dates will either return the same infinite dates (e.g., `greatest`) or `NULL` (e.g., `date_part`) depending on what "makes sense". In general, if the function needs to examine the parts of the infinite date, the result will be `NULL`.

Date Part Functions

The `date_part`, `date_trunc` and `date_diff` functions can be used to extract or manipulate parts of temporal types such as `TIMESTAMP`, `TIMESTAMPTZ`, `DATE` and `INTERVAL`.

The parts to be extracted or manipulated are specified by one of the strings in the tables below. The example column provides the corresponding parts of the timestamp `2021-08-03 11:59:44.123456`. Only the entries of the first table can be extracted from `INTERVAL`s or used to construct them.

> Except for `julian` and `epoch`, which return `DOUBLE`s, all parts are extracted as integers. Since there are no infinite integer values in DuckDB, `NULL`s are returned for infinite timestamps.

Part Specifiers Usable as Date Part Specifiers and in Intervals

Specifier	Description	Synonyms	Example
`century`	Gregorian century	`cent`, `centuries`, `c`	21
`day`	Gregorian day	`days`, `d`, `dayofmonth`	3
`decade`	Gregorian decade	`dec`, `decades`, `decs`	202
`hour`	Hours	`hr`, `hours`, `hrs`, `h`	11
`microseconds`	Sub-minute microseconds	`microsecond`, `us`, `usec`, `usecs`, `usecond`, `useconds`	44123456
`millennium`	Gregorian millennium	`mil`, `millenniums`, `millenia`, `mils`, `millenium`	3
`milliseconds`	Sub-minute milliseconds	`millisecond`, `ms`, `msec`, `msecs`, `msecond`, `mseconds`	44123
`minute`	Minutes	`min`, `minutes`, `mins`, `m`	59
`month`	Gregorian month	`mon`, `months`, `mons`	8
`quarter`	Quarter of the year (1-4)	`quarters`	3
`second`	Seconds	`sec`, `seconds`, `secs`, `s`	44
`year`	Gregorian year	`yr`, `y`, `years`, `yrs`	2021

Part Specifiers Only Usable as Date Part Specifiers

Specifier	Description	Synonyms	Example
`dayofweek`	Day of the week (Sunday = 0, Saturday = 6)	`weekday`, `dow`	2
`dayofyear`	Day of the year (1-365/366)	`doy`	215
`epoch`	Seconds since 1970-01-01		1760465850.6698709
`era`	Gregorian era (CE/AD, BCE/BC)		1
`isodow`	ISO day of the week (Monday = 1, Sunday = 7)		2
`isoyear`	ISO Year number (Starts on Monday of week containing Jan 4th)		2021
`julian`	Julian Day number.		2459430.4998162435
`timezone_hour`	Time zone offset hour portion		0
`timezone_minute`	Time zone offset minute portion		0
`timezone`	Time zone offset in seconds		0

Specifier	Description	Synonyms	Example
week	Week number	weeks, w	31
yearweek	ISO year and week number in YYYYWW format		202131

Note that the time zone parts are all zero unless a time zone extension such as ICU has been installed to support `TIMESTAMP WITH TIME ZONE`.

Part Functions

There are dedicated extraction functions to get certain subfields:

Name	Description
century(date)	Century.
day(date)	Day.
dayofmonth(date)	Day (synonym).
dayofweek(date)	Numeric weekday (Sunday = 0, Saturday = 6).
dayofyear(date)	Day of the year (starts from 1, i.e., January 1 = 1).
decade(date)	Decade (year / 10).
epoch(date)	Seconds since 1970-01-01.
era(date)	Calendar era.
hour(date)	Hours.
isodow(date)	Numeric ISO weekday (Monday = 1, Sunday = 7).
isoyear(date)	ISO Year number (Starts on Monday of week containing Jan 4th).
julian(date)	DOUBLE Julian Day number.
microsecond(date)	Sub-minute microseconds.
millennium(date)	Millennium.
millisecond(date)	Sub-minute milliseconds.
minute(date)	Minutes.
month(date)	Month.
quarter(date)	Quarter.
second(date)	Seconds.
timezone_hour(date)	Time zone offset hour portion.
timezone_minute(date)	Time zone offset minutes portion.
timezone(date)	Time zone offset in seconds.
week(date)	ISO Week.
weekday(date)	Numeric weekday synonym (Sunday = 0, Saturday = 6).
weekofyear(date)	ISO Week (synonym).
year(date)	Year.
yearweek(date)	BIGINT of combined ISO Year number and 2-digit version of ISO Week number.

century(date)

Description	Century.
Example	`century(DATE '1992-02-15')`
Result	`20`

day(date)

Description	Day.
Example	`day(DATE '1992-02-15')`
Result	`15`

dayofmonth(date)

Description	Day (synonym).
Example	`dayofmonth(DATE '1992-02-15')`
Result	`15`

dayofweek(date)

Description	Numeric weekday (Sunday = 0, Saturday = 6).
Example	`dayofweek(DATE '1992-02-15')`
Result	`6`

dayofyear(date)

Description	Day of the year (starts from 1, i.e., January 1 = 1).
Example	`dayofyear(DATE '1992-02-15')`
Result	`46`

decade(date)

Description	Decade (year / 10).
Example	`decade(DATE '1992-02-15')`
Result	`199`

epoch(date)

Description	Seconds since 1970-01-01.
Example	`epoch(DATE '1992-02-15')`

Result	`698112000`

`era(date)`

Description	Calendar era.
Example	`era(DATE '0044-03-15 (BC)')`
Result	`0`

`hour(date)`

Description	Hours.
Example	`hour(timestamp '2021-08-03 11:59:44.123456')`
Result	`11`

`isodow(date)`

Description	Numeric ISO weekday (Monday = 1, Sunday = 7).
Example	`isodow(DATE '1992-02-15')`
Result	`6`

`isoyear(date)`

Description	ISO Year number (Starts on Monday of week containing Jan 4th).
Example	`isoyear(DATE '2022-01-01')`
Result	`2021`

`julian(date)`

Description	DOUBLE Julian Day number.
Example	`julian(DATE '1992-09-20')`
Result	`2448886.0`

`microsecond(date)`

Description	Sub-minute microseconds.
Example	`microsecond(timestamp '2021-08-03 11:59:44.123456')`
Result	`44123456`

millennium(date)

Description	Millennium.
Example	`millennium(DATE '1992-02-15')`
Result	2

millisecond(date)

Description	Sub-minute milliseconds.
Example	`millisecond(timestamp '2021-08-03 11:59:44.123456')`
Result	44123

minute(date)

Description	Minutes.
Example	`minute(timestamp '2021-08-03 11:59:44.123456')`
Result	59

month(date)

Description	Month.
Example	`month(DATE '1992-02-15')`
Result	2

quarter(date)

Description	Quarter.
Example	`quarter(DATE '1992-02-15')`
Result	1

second(date)

Description	Seconds.
Example	`second(timestamp '2021-08-03 11:59:44.123456')`
Result	44

timezone_hour(date)

Description	Time zone offset hour portion.
Example	`timezone_hour(DATE '1992-02-15')`

Result	`0`

`timezone_minute(date)`

Description	Time zone offset minutes portion.
Example	`timezone_minute(DATE '1992-02-15')`
Result	`0`

`timezone(date)`

Description	Time zone offset in minutes.
Example	`timezone(DATE '1992-02-15')`
Result	`0`

`week(date)`

Description	ISO Week.
Example	`week(DATE '1992-02-15')`
Result	`7`

`weekday(date)`

Description	Numeric weekday synonym (Sunday = 0, Saturday = 6).
Example	`weekday(DATE '1992-02-15')`
Result	`6`

`weekofyear(date)`

Description	ISO Week (synonym).
Example	`weekofyear(DATE '1992-02-15')`
Result	`7`

`year(date)`

Description	Year.
Example	`year(DATE '1992-02-15')`
Result	`1992`

`yearweek(date)`

Description	BIGINT of combined ISO Year number and 2-digit version of ISO Week number.
Example	`yearweek(DATE '1992-02-15')`
Result	`199207`

Enum Functions

This section describes functions and operators for examining and manipulating ENUM values. The examples assume an enum type created as:

```
CREATE TYPE mood AS ENUM ('sad', 'ok', 'happy', 'anxious');
```

These functions can take `NULL` or a specific value of the type as argument(s). With the exception of `enum_range_boundary`, the result depends only on the type of the argument and not on its value.

Name	Description
`enum_code(enum_value)`	Returns the numeric value backing the given enum value.
`enum_first(enum)`	Returns the first value of the input enum type.
`enum_last(enum)`	Returns the last value of the input enum type.
`enum_range(enum)`	Returns all values of the input enum type as an array.
`enum_range_boundary(enum, enum)`	Returns the range between the two given enum values as an array.

`enum_code(enum_value)`

Description	Returns the numeric value backing the given enum value.
Example	`enum_code('happy'::mood)`
Result	2

`enum_first(enum)`

Description	Returns the first value of the input enum type.
Example	`enum_first(NULL::mood)`
Result	`sad`

`enum_last(enum)`

Description	Returns the last value of the input enum type.
Example	`enum_last(NULL::mood)`
Result	`anxious`

`enum_range(enum)`

Description	Returns all values of the input enum type as an array.
Example	`enum_range(NULL::mood)`
Result	`[sad, ok, happy, anxious]`

`enum_range_boundary(enum, enum)`

Description	Returns the range between the two given enum values as an array. The values must be of the same enum type. When the first parameter is `NULL`, the result starts with the first value of the enum type. When the second parameter is `NULL`, the result ends with the last value of the enum type.
Example	`enum_range_boundary(NULL, 'happy'::mood)`
Result	`[sad, ok, happy]`

Geometry Functions

This section describes the functions for for examining and manipulating `GEOMETRY` values.

> **Note.**: The `spatial` extension provides additional functions for working with `GEOMETRY` values, which are documented in the Spatial Functions section.

Geometry Operators

The table below lists the operators that can be used with `GEOMETRY` values.

Operator	Description	Example	Result
&&	Returns true if the geometries bounding boxes intersect. Equivalent to `ST_IntersectsExtent`.	`'POINT(5 5)'::GEOMETRY && 'LINESTRING(0 0, 10 20)'::GEOMETRY`	`true`

Built-in Geometry Functions

Name	Description
`ST_GeomFromWKB`	Creates a geometry from Well-Known Binary (WKB) representation
`ST_AsWKB`	Returns the Well-Known Binary (WKB) representation of the geometry
`ST_AsWKT`	Returns the Well-Known Text (WKT) representation of the geometry
`ST_Intersects_Extent`	Returns true if the geometries bounding boxes intersect
`ST_CRS`	Returns the Coordinate Reference System (CRS) identifier of the geometry
`ST_SetCRS`	Sets the Coordinate Reference System (CRS) identifier of the geometry

`ST_GeomFromWKB` function

Description	Creates a geometry from Well-Known Binary (WKB) representation
Example	`ST_GeomFromWKB('\x01\x01\x00\x00\x00\x00\x00\x00\x00\x00\x00\xF0?\x00\x00\x00\x00`
Result	`POINT(1 2)`

`ST_AsWKB` function

Description	Returns the Well-Known Binary (WKB) representation of the geometry
Example	`ST_AsWKB('POINT(1 2)::GEOMETRY')`
Result	`\x01\x01\x00\x00\x00\x00\x00\x00\x00\x00\x00\xF0?\x00\x00\x00\x00\x00\x00\x00`
Alias	`ST_AsBinary`

`ST_AsWKT` function

Description	Returns the Well-Known Text (WKT) representation of the geometry
Example	`ST_AsText('POINT(1 2)'::GEOMETRY)`
Result	`POINT (1 2)`
Alias	`ST_AsText`

`ST_Intersects_Extent` function

Description	Returns true if the geometries bounding boxes intersect
Example	`'POINT(5 5)'::GEOMETRY && 'LINESTRING(0 0, 10 20)'::GEOMETRY`
Result	`true`
Alias	`&&`

`ST_CRS` function

Description	Returns the Coordinate Reference System (CRS) identifier of the geometry
Example	`ST_CRS('POINT(1 2)'::GEOMETRY('OGC:CRS84'))`
Result	`OGC:CRS84`

`ST_SetCRS` function

Description	Sets the Coordinate Reference System (CRS) identifier of the geometry
Example	`typeof(ST_SetCRS('POINT(1 2)'::GEOMETRY, 'OGC:CRS84'))`
Result	`GEOMETRY('OGC:CRS84')`

Interval Functions

This section describes functions and operators for examining and manipulating `INTERVAL` values.

Interval Operators

The table below shows the available mathematical operators for `INTERVAL` types.

Operator	Description	Example	Result
`+`	Addition of an `INTERVAL`	`INTERVAL 1 HOUR + INTERVAL 5 HOUR`	`INTERVAL 6 HOUR`
`+`	Addition to a `DATE`	`DATE '1992-03-22' + INTERVAL 5 DAY`	`1992-03-27 00:00:00`
`+`	Addition to a `TIMESTAMP`	`TIMESTAMP '1992-03-22 01:02:03' + INTERVAL 5 DAY`	`1992-03-27 01:02:03`
`+`	Addition to a `TIME`	`TIME '01:02:03' + INTERVAL 5 HOUR`	`06:02:03`
`-`	Subtraction of an `INTERVAL`	`INTERVAL 5 HOUR - INTERVAL 1 HOUR`	`INTERVAL 4 HOUR`
`-`	Subtraction from a `DATE`	`DATE '1992-03-27' - INTERVAL 5 DAY`	`1992-03-22`
`-`	Subtraction from a `TIMESTAMP`	`TIMESTAMP '1992-03-27 01:02:03' - INTERVAL 5 DAY`	`1992-03-22 01:02:03`
`-`	Subtraction from a `TIME`	`TIME '06:02:03' - INTERVAL 5 HOUR`	`01:02:03`

Interval Functions

The table below shows the available scalar functions for `INTERVAL` types.

Name	Description
`date_part(part, interval)`	Extract datepart component (equivalent to `extract`). See `INTERVAL` for the sometimes surprising rules governing this extraction.
`datepart(part, interval)`	Alias of `date_part`.
`extract(part FROM interval)`	Alias of `date_part`.
`epoch(interval)`	Get total number of seconds, as double precision floating point number, in interval.
`to_centuries(integer)`	Construct a century interval.
`to_days(integer)`	Construct a day interval.
`to_decades(integer)`	Construct a decade interval.
`to_hours(integer)`	Construct an hour interval.
`to_microseconds(integer)`	Construct a microsecond interval.
`to_millennia(integer)`	Construct a millennium interval.
`to_milliseconds(integer)`	Construct a millisecond interval.
`to_minutes(integer)`	Construct a minute interval.
`to_months(integer)`	Construct a month interval.
`to_quarters(integer)`	Construct an interval of `integer` quarters.
`to_seconds(integer)`	Construct a second interval.

Name	Description
`to_weeks(integer)`	Construct a week interval.
`to_years(integer)`	Construct a year interval.

> Only the documented date part components are defined for intervals.

`date_part(part, interval)`

Description	Extract datepart component (equivalent to `extract`). See `INTERVAL` for the sometimes surprising rules governing this extraction.
Example	`date_part('year', INTERVAL '14 months')`
Result	`1`

`datepart(part, interval)`

Description	Alias of `date_part`.
Example	`datepart('year', INTERVAL '14 months')`
Result	`1`

`extract(part FROM interval)`

Description	Alias of `date_part`.
Example	`extract('month' FROM INTERVAL '14 months')`
Result	`2`

`epoch(interval)`

Description	Get total number of seconds, as double precision floating point number, in interval.
Example	`epoch(INTERVAL 5 HOUR)`
Result	`18000.0`

`to_centuries(integer)`

Description	Construct a century interval.
Example	`to_centuries(5)`
Result	`INTERVAL 500 YEAR`

`to_days(integer)`

Description	Construct a day interval.
Example	`to_days(5)`
Result	`INTERVAL 5 DAY`

`to_decades(integer)`

Description	Construct a decade interval.
Example	`to_decades(5)`
Result	`INTERVAL 50 YEAR`

`to_hours(integer)`

Description	Construct an hour interval.
Example	`to_hours(5)`
Result	`INTERVAL 5 HOUR`

`to_microseconds(integer)`

Description	Construct a microsecond interval.
Example	`to_microseconds(5)`
Result	`INTERVAL 5 MICROSECOND`

`to_millennia(integer)`

Description	Construct a millennium interval.
Example	`to_millennia(5)`
Result	`INTERVAL 5000 YEAR`

`to_milliseconds(integer)`

Description	Construct a millisecond interval.
Example	`to_milliseconds(5)`
Result	`INTERVAL 5 MILLISECOND`

`to_minutes(integer)`

Description	Construct a minute interval.
Example	`to_minutes(5)`
Result	`INTERVAL 5 MINUTE`

`to_months(integer)`

Description	Construct a month interval.
Example	`to_months(5)`
Result	`INTERVAL 5 MONTH`

`to_quarters(integer)`

Description	Construct an interval of `integer` quarters.
Example	`to_quarters(5)`
Result	`INTERVAL 1 YEAR 3 MONTHS`

`to_seconds(integer)`

Description	Construct a second interval.
Example	`to_seconds(5)`
Result	`INTERVAL 5 SECOND`

`to_weeks(integer)`

Description	Construct a week interval.
Example	`to_weeks(5)`
Result	`INTERVAL 35 DAY`

`to_years(integer)`

Description	Construct a year interval.
Example	`to_years(5)`
Result	`INTERVAL 5 YEAR`

Lambda Functions

> **Deprecated.** DuckDB v1.3 deprecated the old lambda single arrow syntax (`x -> x + 1`) in favor of the Python-style syntax (`lambda x : x + 1`).
>
> DuckDB v1.3 also introduces a new setting to configure the lambda syntax.

```
SET lambda_syntax = 'DEFAULT';
SET lambda_syntax = 'ENABLE_SINGLE_ARROW';
SET lambda_syntax = 'DISABLE_SINGLE_ARROW';
```

> Currently, `DEFAULT` enables both syntax styles, i.e., the old single arrow syntax and the Python-style syntax.
>
> DuckDB v1.5 is the last release supporting the single arrow syntax without explicitly enabling it.
>
> DuckDB v2.0 will disable the single arrow syntax by default.

> DuckDB v2.1 will remove the `lambda_syntax` flag and fully deprecates the single arrow syntax, so the old behavior will no longer be possible.

Lambda functions enable the use of more complex and flexible expressions in queries. DuckDB supports several scalar functions that operate on LISTs and accept lambda functions as parameters in the form `lambda <parameter1>, <parameter2>, ... : <expression>`{:.language-sql .highlight}. If the lambda function has only one parameter, then the parentheses can be omitted. The parameters can have any names. For example, the following are all valid lambda functions:

- `lambda param : param > 1`{:.language-sql .highlight}
- `lambda s : contains(concat(s, 'DB'), 'duck')`{:.language-sql .highlight}
- `lambda acc, x : acc + x`{:.language-sql .highlight}

Scalar Functions That Accept Lambda Functions

Function	Description
`apply(list, lambda(x))`	Alias for `list_transform`.
`array_apply(list, lambda(x))`	Alias for `list_transform`.
`array_filter(list, lambda(x))`	Alias for `list_filter`.
`array_reduce(list, lambda(x, y)[, initial_value])`	Alias for `list_reduce`.
`array_transform(list, lambda(x))`	Alias for `list_transform`.
`filter(list, lambda(x))`	Alias for `list_filter`.
`list_apply(list, lambda(x))`	Alias for `list_transform`.
`list_filter(list, lambda(x))`	Constructs a list from those elements of the input `list` for which the `lambda` function returns `true`. DuckDB must be able to cast the `lambda` function's return type to `BOOL`. The return type of `list_filter` is the same as the input list's. See `list_filter` examples.
`list_reduce(list, lambda(x, y)[, initial_value])`	Reduces all elements of the input `list` into a single scalar value by executing the `lambda` function on a running result and the next list element. The `lambda` function has an optional `initial_value` argument. See `list_reduce` examples.
`list_transform(list, lambda(x))`	Returns a list that is the result of applying the `lambda` function to each element of the input `list`. The return type is defined by the return type of the `lambda` function. See `list_transform` examples.
`reduce(list, lambda(x, y)[, initial_value])`	Alias for `list_reduce`.

`list_filter(list, lambda(x))`

Description	Constructs a list from those elements of the input `list` for which the `lambda` function returns `true`. DuckDB must be able to cast the `lambda` function's return type to `BOOL`. The return type of `list_filter` is the same as the input list's. See `list_filter` examples.
Example	`list_filter([3, 4, 5], lambda x : x > 4)`

Result	`[5]`
Aliases	`array_filter`, `filter`

`list_reduce(list, lambda(x, y)[, initial_value])`

Description	Reduces all elements of the input `list` into a single scalar value by executing the `lambda` function on a running result and the next list element. The `lambda` function has an optional `initial_value` argument. See `list_reduce` examples.
Example	`list_reduce([1, 2, 3], lambda x, y : x + y)`
Result	6
Aliases	`array_reduce`, `reduce`

`list_transform(list, lambda(x))`

Description	Returns a list that is the result of applying the `lambda` function to each element of the input `list`. The return type is defined by the return type of the `lambda` function. See `list_transform` examples.
Example	`list_transform([1, 2, 3], lambda x : x + 1)`
Result	`[2, 3, 4]`
Aliases	`apply`, `array_apply`, `array_transform`, `list_apply`

Nesting Lambda Functions

All scalar functions can be arbitrarily nested. For example, nested lambda functions to get all squares of even list elements:

```
SELECT list_transform(
        list_filter([0, 1, 2, 3, 4, 5], lambda x: x % 2 = 0),
        lambda y: y * y
    );
```

```
[0, 4, 16]
```

Nested lambda function to add each element of the first list to the sum of the second list:

```
SELECT list_transform(
        [1, 2, 3],
        lambda x :
            list_reduce([4, 5, 6], lambda a, b: a + b) + x
    );
```

```
[16, 17, 18]
```

Scoping

Lambda functions conform to scoping rules in the following order:

- inner lambda parameters
- outer lambda parameters
- column names

- macro parameters

```
CREATE TABLE tbl (x INTEGER);
INSERT INTO tbl VALUES (10);
SELECT list_apply(
            [1, 2],
            lambda x: list_apply([4], lambda x: x + tbl.x)[1] + x
    )
FROM tbl;
```

```
[15, 16]
```

Indexes as Parameters

All lambda functions accept an optional extra parameter that represents the index of the current element. This is always the last parameter of the lambda function (e.g., `i` in `(x, i)`), and is 1-based (i.e., the first element has index 1).

Get all elements that are larger than their index:

```
SELECT list_filter([1, 3, 1, 5], lambda x, i: x > i);
```

```
[3, 5]
```

Examples

`list_transform` Examples

Incrementing each list element by one:

```
SELECT list_transform([1, 2, NULL, 3], lambda x: x + 1);
```

```
[2, 3, NULL, 4]
```

Transforming strings:

```
SELECT list_transform(['Duck', 'Goose', 'Sparrow'], lambda s: concat(s, 'DB'));
```

```
[DuckDB, GooseDB, SparrowDB]
```

Combining lambda functions with other functions:

```
SELECT list_transform([5, NULL, 6], lambda x: coalesce(x, 0) + 1);
```

```
[6, 1, 7]
```

`list_filter` Examples

Filter out negative values:

```
SELECT list_filter([5, -6, NULL, 7], lambda x: x > 0);
```

```
[5, 7]
```

Divisible by 2 and 5:

```
SELECT list_filter(
        list_filter([2, 4, 3, 1, 20, 10, 3, 30], lambda x: x % 2 = 0),
        lambda y: y % 5 = 0
    );
```

```
[20, 10, 30]
```

In combination with `range(...)` to construct lists:

```
SELECT list_filter([1, 2, 3, 4], lambda x: x > #1) FROM range(4);
```

```
[1, 2, 3, 4]
[2, 3, 4]
[3, 4]
[4]
```

`list_reduce` Examples

Sum of all list elements:

```
SELECT list_reduce([1, 2, 3, 4], lambda acc, x: acc + x);
```

```
10
```

Only add up list elements if they are greater than 2:

```
SELECT list_reduce(
        list_filter([1, 2, 3, 4], lambda x: x > 2),
        lambda acc, x: acc + x
    );
```

```
7
```

Concat all list elements:

```
SELECT list_reduce(['DuckDB', 'is', 'awesome'], lambda acc, x: concat(acc, ' ', x));
```

```
DuckDB is awesome
```

Concatenate elements with the index without an initial value:

```
SELECT list_reduce(
        ['a', 'b', 'c', 'd'],
        lambda x, y, i: x || ' - ' || CAST(i AS VARCHAR) || ' - ' || y
    );
```

```
a - 2 - b - 3 - c - 4 - d
```

Concatenate elements with the index with an initial value:

```
SELECT list_reduce(
        ['a', 'b', 'c', 'd'],
        lambda x, y, i: x || ' - ' || CAST(i AS VARCHAR) || ' - ' || y, 'INITIAL'
    );
```

```
INITIAL - 1 - a - 2 - b - 3 - c - 4 - d
```

Limitations

Subqueries in lambda expressions are currently not supported. For example:

```
SELECT list_apply([1, 2, 3], lambda x: (SELECT 42) + x);
```

```
Binder Error:
subqueries in lambda expressions are not supported
```

List Functions

Function	Description
`list[index]`	Extracts a single list element using a (1-based) `index`.
`list[begin[:end][:step]]`	Extracts a sublist using slice conventions. Negative values are accepted.
`list1 && list2`	Alias for `list_has_any`.
`list1 <-> list2`	Alias for `list_distance`.
`list1 <=> list2`	Alias for `list_cosine_distance`.
`list1 <@ list2`	Alias for `list_has_all`.
`list1 @> list2`	Alias for `list_has_all`.
`arg1 || arg2`	Concatenates two strings, lists, or blobs. Any `NULL` input results in `NULL`. See also `concat(arg1, arg2, ...)` and `list_concat(list1, list2, ...)`.
`aggregate(list, function_name, ...)`	Alias for `list_aggregate`.
`apply(list, lambda(x))`	Alias for `list_transform`.
`array_aggr(list, function_name, ...)`	Alias for `list_aggregate`.
`array_aggregate(list, function_name, ...)`	Alias for `list_aggregate`.
`array_append(list, element)`	Alias for `list_append`.
`array_apply(list, lambda(x))`	Alias for `list_transform`.
`array_cat(list_1, ..., list_n)`	Alias for `list_concat`.
`array_concat(list_1, ..., list_n)`	Alias for `list_concat`.
`array_contains(list, element)`	Alias for `list_contains`.
`array_distinct(list)`	Alias for `list_distinct`.
`array_extract(list, index)`	Extracts the `index`th (1-based) value from the `list`.
`array_filter(list, lambda(x))`	Alias for `list_filter`.
`array_grade_up(list[, col1][, col2])`	Alias for `list_grade_up`.
`array_has(list, element)`	Alias for `list_contains`.
`array_has_all(list1, list2)`	Alias for `list_has_all`.
`array_has_any(list1, list2)`	Alias for `list_has_any`.
`array_indexof(list, element)`	Alias for `list_position`.

Function	Description
`array_intersect(list1, list2)`	Alias for `list_intersect`.
`array_length(list)`	Alias for `length`.
`array_pop_back(list)`	Returns the `list` without the last element.
`array_pop_front(list)`	Returns the `list` without the first element.
`array_position(list, element)`	Alias for `list_position`.
`array_prepend(element, list)`	Alias for `list_prepend`.
`array_push_back(list, element)`	Alias for `list_append`.
`array_push_front(list, element)`	Prepends `element` to `list`.
`array_reduce(list, lambda(x,y)[, initial_value])`	Alias for `list_reduce`.
`array_resize(list, size[[, value]])`	Alias for `list_resize`.
`array_reverse(list)`	Alias for `list_reverse`.
`array_reverse_sort(list[, col1])`	Alias for `list_reverse_sort`.
`array_select(value_list, index_list)`	Alias for `list_select`.
`array_slice(list, begin, end)`	Alias for `list_slice`.
`array_slice(list, begin, end, step)`	Alias for `list_slice`.
`array_sort(list[, col1][, col2])`	Alias for `list_sort`.
`array_to_string(list, delimiter)`	Concatenates list/array elements using an optional `delimiter`.
`array_to_string_comma_default(array)`	Concatenates list/array elements with a comma delimiter.
`array_transform(list, lambda(x))`	Alias for `list_transform`.
`array_unique(list)`	Alias for `list_unique`.
`array_where(value_list, mask_list)`	Alias for `list_where`.
`array_zip(list_1, ..., list_n[, truncate])`	Alias for `list_zip`.
`char_length(list)`	Alias for `length`.
`character_length(list)`	Alias for `length`.
`concat(value, ...)`	Concatenates multiple strings or lists. `NULL` inputs are skipped. See also operator `||`.
`contains(list, element)`	Returns `true` if the `list` contains the `element`.

Function	Description
`filter(list, lambda(x))`	Alias for `list_filter`.
`flatten(nested_list)`	Flattens a nested list by one level.
`generate_series(start[, stop][, step])`	Creates a list of values between `start` and `stop` - the stop parameter is inclusive.
`grade_up(list[, col1][, col2])`	Alias for `list_grade_up`.
`len(list)`	Alias for `length`.
`length(list)`	Returns the length of the `list`.
`list_aggr(list, function_name, ...)`	Alias for `list_aggregate`.
`list_aggregate(list, function_name, ...)`	Executes the aggregate function `function_name` on the elements of `list`. See the List Aggregates section for more details.
`list_any_value(list)`	Applies aggregate function `any_value` to the `list`.
`list_append(list, element)`	Appends `element` to `list`.
`list_apply(list, lambda(x))`	Alias for `list_transform`.
`list_approx_count_distinct(list)`	Applies aggregate function `approx_count_distinct` to the `list`.
`list_avg(list)`	Applies aggregate function `avg` to the `list`.
`list_bit_and(list)`	Applies aggregate function `bit_and` to the `list`.
`list_bit_or(list)`	Applies aggregate function `bit_or` to the `list`.
`list_bit_xor(list)`	Applies aggregate function `bit_xor` to the `list`.
`list_bool_and(list)`	Applies aggregate function `bool_and` to the `list`.
`list_bool_or(list)`	Applies aggregate function `bool_or` to the `list`.
`list_cat(list_1, ..., list_n)`	Alias for `list_concat`.
`list_concat(list_1, ..., list_n)`	Concatenates lists. `NULL` inputs are skipped. See also operator `||`.
`list_contains(list, element)`	Returns true if the list contains the element.
`list_cosine_distance(list1, list2)`	Computes the cosine distance between two same-sized lists.
`list_cosine_similarity(list1, list2)`	Computes the cosine similarity between two same-sized lists.
`list_count(list)`	Applies aggregate function `count` to the `list`.
`list_distance(list1, list2)`	Calculates the Euclidean distance between two points with coordinates given in two inputs lists of equal length.
`list_distinct(list)`	Removes all duplicates and `NULL` values from a list. Does not preserve the original order.
`list_dot_product(list1, list2)`	Alias for `list_inner_product`.
`list_element(list, index)`	Alias for `list_extract`.
`list_entropy(list)`	Applies aggregate function `entropy` to the `list`.

Function	Description
`list_extract(list, index)`	Extract the `index`th (1-based) value from the list.
`list_filter(list, lambda(x))`	Constructs a list from those elements of the input `list` for which the `lambda` function returns `true`. DuckDB must be able to cast the `lambda` function's return type to `BOOL`. The return type of `list_filter` is the same as the input list's. See `list_filter` examples.
`list_first(list)`	Applies aggregate function `first` to the `list`.
`list_grade_up(list[, col1][, col2])`	Works like `list_sort`, but the results are the indexes that correspond to the position in the original list instead of the actual values.
`list_has(list, element)`	Alias for `list_contains`.
`list_has_all(list1, list2)`	Returns true if all elements of list2 are in list1. NULLs are ignored.
`list_has_any(list1, list2)`	Returns true if the lists have any element in common. NULLs are ignored.
`list_histogram(list)`	Applies aggregate function `histogram` to the `list`.
`list_indexof(list, element)`	Alias for `list_position`.
`list_inner_product(list1, list2)`	Computes the inner product between two same-sized lists.
`list_intersect(list1, list2)`	Returns a list of all the elements that exist in both `list1` and `list2`, without duplicates.
`list_kurtosis(list)`	Applies aggregate function `kurtosis` to the `list`.
`list_kurtosis_pop(list)`	Applies aggregate function `kurtosis_pop` to the `list`.
`list_last(list)`	Applies aggregate function `last` to the `list`.
`list_mad(list)`	Applies aggregate function `mad` to the `list`.
`list_max(list)`	Applies aggregate function `max` to the `list`.
`list_median(list)`	Applies aggregate function `median` to the `list`.
`list_min(list)`	Applies aggregate function `min` to the `list`.
`list_mode(list)`	Applies aggregate function `mode` to the `list`.
`list_negative_dot_product(list1, list2)`	Alias for `list_negative_inner_product`.
`list_negative_inner_product(list1, list2)`	Computes the negative inner product between two same-sized lists.
`list_pack(arg, ...)`	Alias for `list_value`.
`list_position(list, element)`	Returns the index of the `element` if the `list` contains the `element`. If the `element` is not found, it returns `NULL`.
`list_prepend(element, list)`	Prepends `element` to `list`.
`list_product(list)`	Applies aggregate function `product` to the `list`.
`list_reduce(list, lambda(x,y)[, initial_value])`	Reduces all elements of the input `list` into a single scalar value by executing the `lambda` function on a running result and the next list element. The `lambda` function has an optional `initial_value` argument. See `list_reduce` examples.
`list_resize(list, size[[, value]])`	Resizes the `list` to contain `size` elements. Initializes new elements with `value` or `NULL` if `value` is not set.
`list_reverse(list)`	Reverses the `list`.

Function	Description
`list_reverse_sort(list[, col1])`	Sorts the elements of the list in reverse order. See the Sorting Lists section for more details about sorting order and `NULL` values.
`list_select(value_list, index_list)`	Returns a list based on the elements selected by the `index_list`.
`list_sem(list)`	Applies aggregate function `sem` to the `list`.
`list_skewness(list)`	Applies aggregate function `skewness` to the `list`.
`list_slice(list, begin, end)`	Extracts a sublist or substring using slice conventions. Negative values are accepted.
`list_slice(list, begin, end, step)`	list_slice with added step feature.
`list_sort(list[, col1][, col2])`	Sorts the elements of the list. See the Sorting Lists section for more details about sorting order and `NULL` values.
`list_stddev_pop(list)`	Applies aggregate function `stddev_pop` to the `list`.
`list_stddev_samp(list)`	Applies aggregate function `stddev_samp` to the `list`.
`list_string_agg(list)`	Applies aggregate function `string_agg` to the `list`.
`list_sum(list)`	Applies aggregate function `sum` to the `list`.
`list_transform(list, lambda(x))`	Returns a list that is the result of applying the `lambda` function to each element of the input `list`. The return type is defined by the return type of the `lambda` function. See `list_transform` examples.
`list_unique(list)`	Counts the unique elements of a `list`.
`list_value(arg, ...)`	Creates a LIST containing the argument values.
`list_var_pop(list)`	Applies aggregate function `var_pop` to the `list`.
`list_var_samp(list)`	Applies aggregate function `var_samp` to the `list`.
`list_where(value_list, mask_list)`	Returns a list with the BOOLEANs in `mask_list` applied as a mask to the `value_list`.
`list_zip(list_1, ..., list_n[, truncate])`	Zips n `LIST`s to a new `LIST` whose length will be that of the longest list. Its elements are structs of n elements from each list `list_1`, …, `list_n`, missing elements are replaced with `NULL`. If `truncate` is set, all lists are truncated to the smallest list length.
`range(start[, stop][, step])`	Creates a list of values between `start` and `stop` - the stop parameter is exclusive.
`reduce(list, lambda(x,y)[, initial_value])`	Alias for `list_reduce`.
`repeat(list, count)`	Repeats the `list` `count` number of times.
`unnest(list)`	Unnests a list by one level. Note that this is a special function that alters the cardinality of the result. See the unnest page for more details.
`unpivot_list(arg, ...)`	Identical to list_value, but generated as part of unpivot for better error messages.

`list[index]`

Description	Extracts a single list element using a (1-based) `index`.
Example	`[4, 5, 6][3]`

Result	6
Alias	`list_extract`

`list[begin[:end][:step]]`

Description	Extracts a sublist using slice conventions. Negative values are accepted.
Example	`[4, 5, 6][3]`
Result	6
Alias	`list_slice`

`arg1 || arg2`

Description	Concatenates two strings, lists, or blobs. Any `NULL` input results in `NULL`. See also `concat(arg1, arg2, ...)` and `list_concat(list1, list2, ...)`.
Example 1	`'Duck' || 'DB'`
Result	DuckDB
Example 2	`[1, 2, 3] || [4, 5, 6]`
Result	`[1, 2, 3, 4, 5, 6]`
Example 3	`'\xAA'::BLOB || '\xBB'::BLOB`
Result	\xAA\xBB

`array_extract(list, index)`

Description	Extracts the `index`th (1-based) value from the `list`.
Example	`array_extract([4, 5, 6], 3)`
Result	6

`array_pop_back(list)`

Description	Returns the `list` without the last element.
Example	`array_pop_back([4, 5, 6])`
Result	`[4, 5]`

`array_pop_front(list)`

Description	Returns the `list` without the first element.
Example	`array_pop_front([4, 5, 6])`
Result	`[5, 6]`

array_push_front(list, element)

Description	Prepends `element` to `list`.
Example	`array_push_front([4, 5, 6], 3)`
Result	`[3, 4, 5, 6]`

array_to_string(list, delimiter)

Description	Concatenates list/array elements using an optional `delimiter`.
Example 1	`array_to_string([1, 2, 3], '-')`
Result	`1-2-3`
Example 2	`array_to_string(['aa', 'bb', 'cc'], '')`
Result	`aabbcc`

array_to_string_comma_default(array)

Description	Concatenates list/array elements with a comma delimiter.
Example	`array_to_string_comma_default(['Banana', 'Apple', 'Melon'])`
Result	`Banana,Apple,Melon`

concat(value, ...)

Description	Concatenates multiple strings or lists. `NULL` inputs are skipped. See also operator `||`.
Example 1	`concat('Hello', ' ', 'World')`
Result	`Hello World`
Example 2	`concat([1, 2, 3], NULL, [4, 5, 6])`
Result	`[1, 2, 3, 4, 5, 6]`

contains(list, element)

Description	Returns `true` if the `list` contains the `element`.
Example	`contains([1, 2, NULL], 1)`
Result	`true`

flatten(nested_list)

Description	Flattens a nested list by one level.
Example	`flatten([[1, 2, 3], [4, 5]])`
Result	`[1, 2, 3, 4, 5]`

`generate_series(start[, stop][, step])`

Description	Creates a list of values between `start` and `stop` - the stop parameter is inclusive.
Example	`generate_series(2, 5, 3)`
Result	`[2, 5]`

`length(list)`

Description	Returns the length of the `list`.
Example	`length([1,2,3])`
Result	3
Aliases	`char_length`, `character_length`, `len`

`list_aggregate(list, function_name, ...)`

Description	Executes the aggregate function `function_name` on the elements of `list`. See the List Aggregates section for more details.
Example	`list_aggregate([1, 2, NULL], 'min')`
Result	1
Aliases	`aggregate`, `array_aggr`, `array_aggregate`, `list_aggr`

`list_any_value(list)`

Description	Applies aggregate function `any_value` to the `list`.
Example	`list_any_value([3,3,9])`
Result	3

`list_append(list, element)`

Description	Appends `element` to `list`.
Example	`list_append([2, 3], 4)`
Result	`[2, 3, 4]`
Aliases	`array_append`, `array_push_back`

`list_approx_count_distinct(list)`

Description	Applies aggregate function `approx_count_distinct` to the `list`.
Example	`list_approx_count_distinct([3,3,9])`
Result	2

`list_avg(list)`

Description	Applies aggregate function `avg` to the `list`.
Example	`list_avg([3,3,9])`
Result	`5.0`

`list_bit_and(list)`

Description	Applies aggregate function `bit_and` to the `list`.
Example	`list_bit_and([3,3,9])`
Result	`1`

`list_bit_or(list)`

Description	Applies aggregate function `bit_or` to the `list`.
Example	`list_bit_or([3,3,9])`
Result	`11`

`list_bit_xor(list)`

Description	Applies aggregate function `bit_xor` to the `list`.
Example	`list_bit_xor([3,3,9])`
Result	`9`

`list_bool_and(list)`

Description	Applies aggregate function `bool_and` to the `list`.
Example	`list_bool_and([true, false])`
Result	`false`

`list_bool_or(list)`

Description	Applies aggregate function `bool_or` to the `list`.
Example	`list_bool_or([true, false])`
Result	`true`

`list_concat(list_1, ..., list_n)`

Description	Concatenates lists. `NULL` inputs are skipped. See also operator `||`.
Example	`list_concat([2, 3], [4, 5, 6], [7])`

Result	`[2, 3, 4, 5, 6, 7]`
Aliases	`list_cat`, `array_concat`, `array_cat`

`list_contains(list, element)`

Description	Returns true if the list contains the element.
Example	`list_contains([1, 2, NULL], 1)`
Result	`true`
Aliases	`array_contains`, `array_has`, `list_has`

`list_cosine_distance(list1, list2)`

Description	Computes the cosine distance between two same-sized lists.
Example	`list_cosine_distance([1, 2, 3], [1, 2, 3])`
Result	`0.0`
Alias	`<=>`

`list_cosine_similarity(list1, list2)`

Description	Computes the cosine similarity between two same-sized lists.
Example	`list_cosine_similarity([1, 2, 3], [1, 2, 3])`
Result	`1.0`

`list_count(list)`

Description	Applies aggregate function `count` to the `list`.
Example	`list_count([3,3,9])`
Result	`3`

`list_distance(list1, list2)`

Description	Calculates the Euclidean distance between two points with coordinates given in two inputs lists of equal length.
Example	`list_distance([1, 2, 3], [1, 2, 5])`
Result	`2.0`
Alias	`<->`

`list_distinct(list)`

Description	Removes all duplicates and NULL values from a list. Does not preserve the original order.
Example	`list_distinct([1, 1, NULL, -3, 1, 5])`
Result	`[5, -3, 1]`
Alias	`array_distinct`

`list_entropy(list)`

Description	Applies aggregate function `entropy` to the `list`.
Example	`list_entropy([3,3,9])`
Result	`0.9182958340544893`

`list_extract(list, index)`

Description	Extract the `index`th (1-based) value from the list.
Example	`list_extract([4, 5, 6], 3)`
Result	`6`
Alias	`list_element`

`list_filter(list, lambda(x))`

Description	Constructs a list from those elements of the input `list` for which the `lambda` function returns `true`. DuckDB must be able to cast the `lambda` function's return type to `BOOL`. The return type of `list_filter` is the same as the input list's. See `list_filter` examples.
Example	`list_filter([3, 4, 5], lambda x : x > 4)`
Result	`[5]`
Aliases	`array_filter`, `filter`

`list_first(list)`

Description	Applies aggregate function `first` to the `list`.
Example	`list_first([3,3,9])`
Result	`3`

`list_grade_up(list[, col1][, col2])`

Description	Works like `list_sort`, but the results are the indexes that correspond to the position in the original list instead of the actual values.
Example	`list_grade_up([3, 6, 1, 2])`
Result	`[3, 4, 1, 2]`
Aliases	`array_grade_up`, `grade_up`

`list_has_all(list1, list2)`

Description	Returns true if all elements of list2 are in list1. NULLs are ignored.
Example	`list_has_all([1, 2, 3], [2, 3])`
Result	`true`
Aliases	`<@`, `@>`, `array_has_all`

`list_has_any(list1, list2)`

Description	Returns true if the lists have any element in common. NULLs are ignored.
Example	`list_has_any([1, 2, 3], [2, 3, 4])`
Result	`true`
Aliases	`&&`, `array_has_any`

`list_histogram(list)`

Description	Applies aggregate function `histogram` to the `list`.
Example	`list_histogram([3,3,9])`
Result	`{3=2, 9=1}`

`list_inner_product(list1, list2)`

Description	Computes the inner product between two same-sized lists.
Example	`list_inner_product([1, 2, 3], [1, 2, 3])`
Result	`14.0`
Alias	`list_dot_product`

`list_intersect(list1, list2)`

Description	Returns a list of all the elements that exist in both `list1` and `list2`, without duplicates.
Example	`list_intersect([1, 2, 3], [2, 3, 4])`
Result	`[3, 2]`
Alias	`array_intersect`

`list_kurtosis(list)`

Description	Applies aggregate function `kurtosis` to the `list`.
Example	`list_kurtosis([3,3,9])`
Result	`NULL`

`list_kurtosis_pop(list)`

Description	Applies aggregate function `kurtosis_pop` to the `list`.
Example	`list_kurtosis_pop([3,3,9])`
Result	`-1.4999999999999978`

`list_last(list)`

Description	Applies aggregate function `last` to the `list`.
Example	`list_last([3,3,9])`
Result	`9`

`list_mad(list)`

Description	Applies aggregate function `mad` to the `list`.
Example	`list_mad([3,3,9])`
Result	`0.0`

`list_max(list)`

Description	Applies aggregate function `max` to the `list`.
Example	`list_max([3,3,9])`
Result	`9`

`list_median(list)`

Description	Applies aggregate function `median` to the `list`.
Example	`list_median([3,3,9])`
Result	`3.0`

`list_min(list)`

Description	Applies aggregate function `min` to the `list`.
Example	`list_min([3,3,9])`
Result	`3`

`list_mode(list)`

Description	Applies aggregate function `mode` to the `list`.
Example	`list_mode([3,3,9])`

Result	3

`list_negative_inner_product(list1, list2)`

Description	Computes the negative inner product between two same-sized lists.
Example	`list_negative_inner_product([1, 2, 3], [1, 2, 3])`
Result	`-14.0`
Alias	`list_negative_dot_product`

`list_position(list, element)`

Description	Returns the index of the `element` if the `list` contains the `element`. If the `element` is not found, it returns `NULL`.
Example	`list_position([1, 2, NULL], 2)`
Result	2
Aliases	`array_indexof`, `array_position`, `list_indexof`

`list_prepend(element, list)`

Description	Prepends `element` to `list`.
Example	`list_prepend(3, [4, 5, 6])`
Result	`[3, 4, 5, 6]`
Alias	`array_prepend`

`list_product(list)`

Description	Applies aggregate function `product` to the `list`.
Example	`list_product([3,3,9])`
Result	`81.0`

`list_reduce(list, lambda(x,y)[, initial_value])`

Description	Reduces all elements of the input `list` into a single scalar value by executing the `lambda` function on a running result and the next list element. The `lambda` function has an optional `initial_value` argument. See `list_reduce` examples.
Example	`list_reduce([1, 2, 3], lambda x, y : x + y)`
Result	6
Aliases	`array_reduce`, `reduce`

`list_resize(list, size[[, value]])`

Description	Resizes the `list` to contain `size` elements. Initializes new elements with `value` or `NULL` if `value` is not set.
Example	`list_resize([1, 2, 3], 5, 0)`
Result	`[1, 2, 3, 0, 0]`
Alias	`array_resize`

`list_reverse(list)`

Description	Reverses the `list`.
Example	`list_reverse([3, 6, 1, 2])`
Result	`[2, 1, 6, 3]`
Alias	`array_reverse`

`list_reverse_sort(list[, col1])`

Description	Sorts the elements of the list in reverse order. See the Sorting Lists section for more details about sorting order and `NULL` values.
Example	`list_reverse_sort([3, 6, 1, 2])`
Result	`[6, 3, 2, 1]`
Alias	`array_reverse_sort`

`list_select(value_list, index_list)`

Description	Returns a list based on the elements selected by the `index_list`.
Example	`list_select([10, 20, 30, 40], [1, 4])`
Result	`[10, 40]`
Alias	`array_select`

`list_sem(list)`

Description	Applies aggregate function `sem` to the `list`.
Example	`list_sem([3,3,9])`
Result	`1.6329931618554523`

`list_skewness(list)`

Description	Applies aggregate function `skewness` to the `list`.
Example	`list_skewness([3,3,9])`
Result	`1.7320508075688796`

`list_slice(list, begin, end)`

Description	Extracts a sublist or substring using slice conventions. Negative values are accepted.
Example	`list_slice([4, 5, 6], 2, 3)`
Result	`[5, 6]`
Alias	`array_slice`

`list_slice(list, begin, end, step)`

Description	list_slice with added step feature.
Example	`list_slice([4, 5, 6], 1, 3, 2)`
Result	`[4, 6]`
Alias	`array_slice`

`list_sort(list[, col1][, col2])`

Description	Sorts the elements of the list. See the Sorting Lists section for more details about sorting order and `NULL` values.
Example	`list_sort([3, 6, 1, 2])`
Result	`[1, 2, 3, 6]`
Alias	`array_sort`

`list_stddev_pop(list)`

Description	Applies aggregate function `stddev_pop` to the `list`.
Example	`list_stddev_pop([3,3,9])`
Result	`2.8284271247461903`

`list_stddev_samp(list)`

Description	Applies aggregate function `stddev_samp` to the `list`.
Example	`list_stddev_samp([3,3,9])`
Result	`3.4641016151377544`

`list_string_agg(list)`

Description	Applies aggregate function `string_agg` to the `list`.
Example	`list_string_agg([3,3,9])`
Result	`3,3,9`

`list_sum(list)`

Description	Applies aggregate function `sum` to the `list`.
Example	`list_sum([3,3,9])`
Result	`15`

`list_transform(list, lambda(x))`

Description	Returns a list that is the result of applying the `lambda` function to each element of the input `list`. The return type is defined by the return type of the `lambda` function. See `list_transform` examples.
Example	`list_transform([1, 2, 3], lambda x : x + 1)`
Result	`[2, 3, 4]`
Aliases	`apply`, `array_apply`, `array_transform`, `list_apply`

`list_unique(list)`

Description	Counts the unique elements of a `list`.
Example	`list_unique([1, 1, NULL, -3, 1, 5])`
Result	`3`
Alias	`array_unique`

`list_value(arg, ...)`

Description	Creates a LIST containing the argument values.
Example	`list_value(4, 5, 6)`
Result	`[4, 5, 6]`
Alias	`list_pack`

`list_var_pop(list)`

Description	Applies aggregate function `var_pop` to the `list`.
Example	`list_var_pop([3,3,9])`
Result	`8.0`

`list_var_samp(list)`

Description	Applies aggregate function `var_samp` to the `list`.
Example	`list_var_samp([3,3,9])`
Result	`12.0`

`list_where(value_list, mask_list)`

Description	Returns a list with the BOOLEANs in `mask_list` applied as a mask to the `value_list`.
Example	`list_where([10, 20, 30, 40], [true, false, false, true])`
Result	`[10, 40]`
Alias	`array_where`

`list_zip(list_1, ..., list_n[, truncate])`

Description	Zips n `LIST`s to a new `LIST` whose length will be that of the longest list. Its elements are structs of n elements from each list `list_1`, …, `list_n`, missing elements are replaced with `NULL`. If `truncate` is set, all lists are truncated to the smallest list length.
Example 1	`list_zip([1, 2], [3, 4], [5, 6])`
Result	`[(1, 3, 5), (2, 4, 6)]`
Example 2	`list_zip([1, 2], [3, 4], [5, 6, 7])`
Result	`[(1, 3, 5), (2, 4, 6), (NULL, NULL, 7)]`
Example 3	`list_zip([1, 2], [3, 4], [5, 6, 7], true)`
Result	`[(1, 3, 5), (2, 4, 6)]`
Alias	`array_zip`

`range(start[, stop][, step])`

Description	Creates a list of values between `start` and `stop` - the stop parameter is exclusive.
Example	`range(2, 5, 3)`
Result	`[2]`

`repeat(list, count)`

Description	Repeats the `list` `count` number of times.
Example	`repeat([1, 2, 3], 5)`
Result	`[1, 2, 3, 1, 2, 3, 1, 2, 3, 1, 2, 3, 1, 2, 3]`

`unnest(list)`

Description	Unnests a list by one level. Note that this is a special function that alters the cardinality of the result. See the unnest page for more details.
Example	`unnest([1, 2, 3])`
Result	Multiple rows: `'1'`,`'2'`,`'3'`

`unpivot_list(arg, ...)`

Description	Identical to list_value, but generated as part of unpivot for better error messages.
Example	`unpivot_list(4, 5, 6)`
Result	`[4, 5, 6]`

List Operators

The following operators are supported for lists:

Operator	Description	Example	Result
`&&`	Alias for `list_has_any`.	`[1, 2, 3, 4, 5] && [2, 5, 5, 6]`	`true`
`@>`	Alias for `list_has_all`, where the list on the **right** of the operator is the sublist.	`[1, 2, 3, 4] @> [3, 4, 3]`	`true`
`<@`	Alias for `list_has_all`, where the list on the **left** of the operator is the sublist.	`[1, 4] <@ [1, 2, 3, 4]`	`true`
`||`	Similar to `list_concat`, except any `NULL` input results in `NULL`.	`[1, 2, 3] || [4, 5, 6]`	`[1, 2, 3, 4, 5, 6]`
`<=>`	Alias for `list_cosine_distance`.	`[1, 2, 3] <=> [1, 2, 5]`	`0.007416606`
`<->`	Alias for `list_distance`.	`[1, 2, 3] <-> [1, 2, 5]`	`2.0`

List Comprehension

Python-style list comprehension can be used to compute expressions over elements in a list. For example:

```
SELECT [lower(x) FOR x IN strings] AS strings
FROM (VALUES (['Hello', '', 'World'])) t(strings);
```

strings
[hello, , world]

```
SELECT [upper(x) FOR x IN strings IF len(x) > 0] AS strings
FROM (VALUES (['Hello', '', 'World'])) t(strings);
```

strings
[HELLO, WORLD]

List comprehensions can also use the position of the list elements by adding a second variable. In the following example, we use `x, i`, where `x` is the value and `i` is the position:

```
SELECT [4, 5, 6] AS l, [x FOR x, i IN l IF i != 2] AS filtered;
```

l	filtered
[4, 5, 6]	[4, 6]

Under the hood, `[f(x) FOR x IN l IF g(x)]` is translated to:

```
l.list_apply(lambda x, i: {'filter': g(x, i), 'result': f(x, i)})
    .list_filter(lambda x: x.filter)
    .list_apply(lambda x: x.result)
```

Range Functions

DuckDB offers two range functions, `range(start, stop, step)` and `generate_series(start, stop, step)`, and their variants with default arguments for `stop` and `step`. The two functions' behavior is different regarding their `stop` argument. This is documented below.

`range`

The `range` function creates a list of values in the range between `start` and `stop`. The `start` parameter is inclusive, while the `stop` parameter is exclusive. The default value of `start` is 0 and the default value of `step` is 1.

Based on the number of arguments, the following variants of `range` exist.

`range(stop)`

```
SELECT range(5);
```

```
[0, 1, 2, 3, 4]
```

`range(start, stop)`

```
SELECT range(2, 5);
```

```
[2, 3, 4]
```

`range(start, stop, step)`

```
SELECT range(2, 5, 3);
```

```
[2]
```

`generate_series`

The `generate_series` function creates a list of values in the range between `start` and `stop`. Both the `start` and the `stop` parameters are inclusive. The default value of `start` is 0 and the default value of `step` is 1. Based on the number of arguments, the following variants of `generate_series` exist.

`generate_series(stop)`

```
SELECT generate_series(5);
```

```
[0, 1, 2, 3, 4, 5]
```

`generate_series(start, stop)`

```
SELECT generate_series(2, 5);
```

```
[2, 3, 4, 5]
```

`generate_series(start, stop, step)`

```
SELECT generate_series(2, 5, 3);
```

```
[2, 5]
```

`generate_subscripts(arr, dim)` The `generate_subscripts(arr, dim)` function generates indexes along the `dim`th dimension of array `arr`.

```
SELECT generate_subscripts([4, 5, 6], 1) AS i;
```

i
1
2
3

Date Ranges

Date ranges are also supported for `TIMESTAMP` and `TIMESTAMP WITH TIME ZONE` values. Note that for these types, the `stop` and `step` arguments have to be specified explicitly (a default value is not provided).

`range` for Date Ranges

```
SELECT *
FROM range(DATE '1992-01-01', DATE '1992-03-01', INTERVAL '1' MONTH);
```

range
1992-01-01 00:00:00
1992-02-01 00:00:00

`generate_series` for Date Ranges

```
SELECT *
FROM generate_series(DATE '1992-01-01', DATE '1992-03-01', INTERVAL '1' MONTH);
```

generate_series
1992-01-01 00:00:00
1992-02-01 00:00:00
1992-03-01 00:00:00

Slicing

The function `list_slice` can be used to extract a sublist from a list. The following variants exist:

- `list_slice(list, begin, end)`
- `list_slice(list, begin, end, step)`
- `array_slice(list, begin, end)`
- `array_slice(list, begin, end, step)`
- `list[begin:end]`
- `list[begin:end:step]`

The arguments are as follows:

- `list`
  - Is the list to be sliced
- `begin`
  - Is the index of the first element to be included in the slice
  - When `begin < 0` the index is counted from the end of the list
  - When `begin < 0` and `-begin > length`, `begin` is clamped to the beginning of the list
  - When `begin > length`, the result is an empty list
  - **Bracket Notation:** When `begin` is omitted, it defaults to the beginning of the list
- `end`
  - Is the index of the last element to be included in the slice
  - When `end < 0` the index is counted from the end of the list
  - When `end > length`, `end` is clamped to `length`
  - When `end < begin`, the result is an empty list
  - **Bracket Notation:** When `end` is omitted, it defaults to the end of the list. When `end` is omitted and a `step` is provided, `end` must be replaced with a `-`
- `step` *(optional)*
  - Is the step size between elements in the slice
  - When `step < 0` the slice is reversed, and `begin` and `end` are swapped
  - Must be non-zero

Examples:

```
SELECT list_slice([1, 2, 3, 4, 5], 2, 4);
```

```
[2, 3, 4]
```

```
SELECT ([1, 2, 3, 4, 5])[2:4:2];
```

```
[2, 4]
```

```
SELECT([1, 2, 3, 4, 5])[4:2:-2];
```

```
[4, 2]
```

```
SELECT ([1, 2, 3, 4, 5])[:];
```

```
[1, 2, 3, 4, 5]
```

```
SELECT ([1, 2, 3, 4, 5])[:-:2];
```

```
[1, 3, 5]
```

```
SELECT ([1, 2, 3, 4, 5])[:-:-2];
```

```
[5, 3, 1]
```

List Aggregates

The function `list_aggregate` allows the execution of arbitrary existing aggregate functions on the elements of a list. Its first argument is the list (column), its second argument is the aggregate function name, e.g., `min`, `histogram` or `sum`.

`list_aggregate` accepts additional arguments after the aggregate function name. These extra arguments are passed directly to the aggregate function, which serves as the second argument of `list_aggregate`.

Order-sensitive aggregate functions are applied in the order of the list. The `ORDER BY`, `DISTINCT` and `FILTER` clauses are not supported by `list_aggregate`. They may instead be emulated using `list_sort`, `list_grade_up`, `list_select`, `list_distinct` and `list_filter`.

```
SELECT list_aggregate([1, 2, -4, NULL], 'min');
```

```
-4
```

```
SELECT list_aggregate([2, 4, 8, 42], 'sum');
```

```
56
```

```
SELECT list_aggregate([[1, 2], [NULL], [2, 10, 3]], 'last');
```

```
[2, 10, 3]
```

```
SELECT list_aggregate([2, 4, 8, 42], 'string_agg', '|');
```

```
2|4|8|42
```

`list_*` Rewrite Functions

The following is a list of existing rewrites. Rewrites simplify the use of the list aggregate function by only taking the list (column) as their argument. `list_avg`, `list_var_samp`, `list_var_pop`, `list_stddev_pop`, `list_stddev_samp`, `list_sem`, `list_approx_count_distinct`, `list_bit_xor`, `list_bit_or`, `list_bit_and`, `list_bool_and`, `list_bool_or`, `list_count`, `list_entropy`, `list_last`, `list_first`, `list_kurtosis`, `list_kurtosis_pop`, `list_min`, `list_max`, `list_product`, `list_skewness`, `list_sum`, `list_string_agg`, `list_mode`, `list_median`, `list_mad` and `list_histogram`.

```
SELECT list_min([1, 2, -4, NULL]);
```

```
-4
```

```
SELECT list_sum([2, 4, 8, 42]);
```

```
56
```

```
SELECT list_last([[1, 2], [NULL], [2, 10, 3]]);
```

```
[2, 10, 3]
```

`array_to_string` Concatenates list/array elements using an optional delimiter.

```
SELECT array_to_string([1, 2, 3], '-') AS str;
```

```
1-2-3
```

This is equivalent to the following SQL:

```
SELECT list_aggr([1, 2, 3], 'string_agg', '-') AS str;
```

```
1-2-3
```

Sorting Lists

The function `list_sort` sorts the elements of a list either in ascending or descending order. In addition, it allows specifying whether `NULL` values should be moved to the beginning or to the end of the list. It has the same sorting behavior as DuckDB's `ORDER BY` clause. Therefore, (nested) values compare the same in `list_sort` as in `ORDER BY`.

By default, if no modifiers are provided, DuckDB sorts `ASC NULLS LAST`. I.e., the values are sorted in ascending order and `NULL` values are placed last. This is identical to the default sort order of SQLite. The default sort order can be changed using `PRAGMA` statements..

`list_sort` leaves it open to the user whether they want to use the default sort order or a custom order. `list_sort` takes up to two additional optional parameters. The second parameter provides the sort order and can be either `ASC` or `DESC`. The third parameter provides the `NULL` order and can be either `NULLS FIRST` or `NULLS LAST`.

This query uses the default sort order and the default `NULL` order.

```
SELECT list_sort([1, 3, NULL, 5, NULL, -5]);
```

```
[-5, 1, 3, 5, NULL, NULL]
```

This query provides the sort order. The `NULL` order uses the configurable default value.

```
SELECT list_sort([1, 3, NULL, 2], 'ASC');
```

```
[1, 2, 3, NULL]
```

This query provides both the sort order and the `NULL` order.

```
SELECT list_sort([1, 3, NULL, 2], 'DESC', 'NULLS FIRST');
```

```
[NULL, 3, 2, 1]
```

`list_reverse_sort` has an optional second parameter providing the `NULL` sort order. It can be either `NULLS FIRST` or `NULLS LAST`.

This query uses the default `NULL` sort order.

```
SELECT list_sort([1, 3, NULL, 5, NULL, -5]);
```

```
[-5, 1, 3, 5, NULL, NULL]
```

This query provides the `NULL` sort order.

```
SELECT list_reverse_sort([1, 3, NULL, 2], 'NULLS LAST');
```

```
[3, 2, 1, NULL]
```

Flattening

The flatten function is a scalar function that converts a list of lists into a single list by concatenating each sub-list together. Note that this only flattens one level at a time, not all levels of sub-lists.

Convert a list of lists into a single list:

```
SELECT
    flatten([
        [1, 2],
        [3, 4]
    ]);
```

```
[1, 2, 3, 4]
```

If the list has multiple levels of lists, only the first level of sub-lists is concatenated into a single list:

```
SELECT
    flatten([
        [
            [1, 2],
            [3, 4],
        ],
        [
            [5, 6],
            [7, 8],
        ]
    ]);
```

```
[[1, 2], [3, 4], [5, 6], [7, 8]]
```

In general, the input to the flatten function should be a list of lists (not a single level list). However, the flatten function has specific behavior when handling empty lists and `NULL` values.

If the input list is empty, return an empty list:

```
SELECT flatten([]);
```

```
[]
```

If the entire input to flatten is `NULL`, return `NULL`:

```
SELECT flatten(NULL);
```

```
NULL
```

If a list whose only entry is `NULL` is flattened, return an empty list:

```
SELECT flatten([NULL]);
```

```
[]
```

If the sub-list in a list of lists only contains `NULL`, do not modify the sub-list:

```
-- (Note the extra set of parentheses vs. the prior example)
SELECT flatten([[NULL]]);
```

```
[NULL]
```

Even if the only contents of each sub-list is `NULL`, still concatenate them together. Note that no de-duplication occurs when flattening. See `list_distinct` function for de-duplication:

```
SELECT flatten([[NULL], [NULL]]);
```

```
[NULL, NULL]
```

Lambda Functions

DuckDB supports lambda functions in the form `lambda parameter1, parameter2, ...: expression`. For details, see the lambda functions page.

Related Functions

- The aggregate functions `list` and `histogram` produce lists and lists of structs.
- The `unnest` function is used to unnest a list by one level.

Map Functions

Name	Description
`cardinality(map)`	Return the size of the map (or the number of entries in the map).
`element_at(map, key)`	Return the value for a given `key` as a list, or an empty list if the key is not contained in the map. The type of the key provided in the second parameter must match the type of the map's keys; else, an error is thrown.
`map_concat(maps...)`	Returns a map created from merging the input `maps`. On key collision the value is taken from the last map with that key.
`map_contains(map, key)`	Checks if a map contains a given key.
`map_contains_entry(map, key, value)`	Check if a map contains a given key-value pair.
`map_contains_value(map, value)`	Checks if a map contains a given value.
`map_entries(map)`	Return a list of struct(k, v) for each key-value pair in the map.
`map_extract(map, key)`	Return the value for a given `key` as a list, or an empty list if the key is not contained in the map. The type of the key provided in the second parameter must match the type of the map's keys; else, an error is thrown.
`map_extract_value(map, key)`	Returns the value for a given `key` or `NULL` if the `key` is not contained in the map. The type of the key provided in the second parameter must match the type of the map's keys; else, an error is thrown.
`map_from_entries(STRUCT(k, v)[])`	Returns a map created from the entries of the array.
`map_keys(map)`	Return a list of all keys in the map.
`map_values(map)`	Return a list of all values in the map.
`map()`	Returns an empty map.
`map[entry]`	Returns the value for a given `key` or `NULL` if the `key` is not contained in the map. The type of the key provided in the second parameter must match the type of the map's keys; else, an error is thrown.

`cardinality(map)`

Description	Return the size of the map (or the number of entries in the map).
Example	`cardinality(map([4, 2], ['a', 'b']))`
Result	2

`element_at(map, key)`

Description	Return the value for a given `key` as a list, or an empty list if the key is not contained in the map. The type of the key provided in the second parameter must match the type of the map's keys; else, an error is thrown.
Example	`element_at(map([100, 5], [42, 43]), 100)`
Result	`[42]`

Aliases	`map_extract(map, key)`

`map_concat(maps...)`

Description	Returns a map created from merging the input `maps`. On key collision the value is taken from the last map with that key.
Example	`map_concat(MAP {'key1': 10, 'key2': 20}, MAP {'key3': 30}, MAP {'key2': 5})`
Result	`{key1=10, key2=5, key3=30}`

`map_contains(map, key)`

Description	Checks if a map contains a given key.
Example	`map_contains(MAP {'key1': 10, 'key2': 20, 'key3': 30}, 'key2')`
Result	`true`

`map_contains_entry(map, key, value)`

Description	Check if a map contains a given key-value pair.
Example	`map_contains_entry(MAP {'key1': 10, 'key2': 20, 'key3': 30}, 'key2', 20)`
Result	`true`

`map_contains_value(map, value)`

Description	Checks if a map contains a given value.
Example	`map_contains_value(MAP {'key1': 10, 'key2': 20, 'key3': 30}, 20)`
Result	`true`

`map_entries(map)`

Description	Return a list of struct(k, v) for each key-value pair in the map.
Example	`map_entries(map([100, 5], [42, 43]))`
Result	`[{'key': 100, 'value': 42}, {'key': 5, 'value': 43}]`

`map_extract(map, key)`

Description	Return the value for a given `key` as a list, or `NULL` if the key is not contained in the map. The type of the key provided in the second parameter must match the type of the map's keys else an error is returned.

Example	`map_extract(map([100, 5], [42, 43]), 100)`
Result	`[42]`
Aliases	`element_at(map, key)`

`map_extract_value(map, key)`

Description	Returns the value for a given `key` or `NULL` if the `key` is not contained in the map. The type of the key provided in the second parameter must match the type of the map's keys; else, an error is thrown.
Example	`map_extract_value(map([100, 5], [42, 43]), 100);`
Result	`42`
Aliases	`map[key]`

`map_from_entries(STRUCT(k, v)[])`

Description	Returns a map created from the entries of the array.
Example	`map_from_entries([{k: 5, v: 'val1'}, {k: 3, v: 'val2'}])`
Result	`{5=val1, 3=val2}`

`map_keys(map)`

Description	Return a list of all keys in the map.
Example	`map_keys(map([100, 5], [42,43]))`
Result	`[100, 5]`

`map_values(map)`

Description	Return a list of all values in the map.
Example	`map_values(map([100, 5], [42, 43]))`
Result	`[42, 43]`

`map()`

Description	Returns an empty map.
Example	`map()`
Result	`{}`

`map[entry]`

Description	Returns the value for a given `key` or `NULL` if the `key` is not contained in the map. The type of the key provided in the second parameter must match the type of the map's keys; else, an error is thrown.
Example	`map([100, 5], ['a', 'b'])[100]`
Result	a
Aliases	`map_extract_value(map, key)`

Nested Functions

There are five nested data types:

Name	Type page	Functions page
`ARRAY`	ARRAY type	ARRAY functions
`LIST`	LIST type	LIST functions
`MAP`	MAP type	MAP functions
`STRUCT`	STRUCT type	STRUCT functions
`UNION`	UNION type	UNION functions

Numeric Functions

Numeric Operators

The table below shows the available mathematical operators for numeric types.

Operator	Description	Example	Result
`+`	Addition	`2 + 3`	`5`
`-`	Subtraction	`2 - 3`	`-1`
`*`	Multiplication	`2 * 3`	`6`
`/`	Float division	`5 / 2`	`2.5`
`//`	Division	`5 // 2`	`2`
`%`	Modulo (remainder)	`5 % 4`	`1`
`**`	Exponent	`3 ** 4`	`81`
`^`	Exponent (alias for `**`)	`3 ^ 4`	`81`
`&`	Bitwise AND	`91 & 15`	`11`
`|`	Bitwise OR	`32 | 3`	`35`
`<<`	Bitwise shift left	`1 << 4`	`16`
`>>`	Bitwise shift right	`8 >> 2`	`2`
`~`	Bitwise negation	`~15`	`-16`
`!`	Factorial of x	`4!`	`24`

Division and Modulo Operators

There are two division operators: `/` and `//`. They are equivalent when at least one of the operands is a `FLOAT` or a `DOUBLE`. When both operands are integers, `/` performs floating points division (`5 / 2 = 2.5`) while `//` performs integer division (`5 // 2 = 2`).

Supported Types

The modulo, bitwise, negation, and factorial operators work only on integral data types, whereas the others are available for all numeric data types.

Numeric Functions

The table below shows the available mathematical functions.

Name	Description
`@(x)`	Absolute value. Parentheses are optional if `x` is a column name.
`abs(x)`	Absolute value.
`acos(x)`	Computes the inverse cosine of `x`.
`acosh(x)`	Computes the inverse hyperbolic cosine of `x`.
`add(x, y)`	Alias for `x + y`.
`asin(x)`	Computes the inverse sine of `x`.
`asinh(x)`	Computes the inverse hyperbolic sine of `x`.
`atan(x)`	Computes the inverse tangent of `x`.
`atanh(x)`	Computes the inverse hyperbolic tangent of `x`.
`atan2(y, x)`	Computes the inverse tangent of `(y, x)`.
`bit_count(x)`	Returns the number of bits that are set.
`cbrt(x)`	Returns the cube root of the number.
`ceil(x)`	Rounds the number up.
`ceiling(x)`	Rounds the number up. Alias of `ceil`.
`cos(x)`	Computes the cosine of `x`.
`cot(x)`	Computes the cotangent of `x`.
`degrees(x)`	Converts radians to degrees.
`divide(x, y)`	Alias for `x // y`.
`even(x)`	Round to next even number by rounding away from zero.
`exp(x)`	Computes `e ** x`.
`factorial(x)`	See the `!` operator. Computes the product of the current integer and all integers below it.
`fdiv(x, y)`	Performs integer division (`x // y`) but returns a `DOUBLE` value.
`floor(x)`	Rounds the number down.
`fmod(x, y)`	Calculates the modulo value. Always returns a `DOUBLE` value.
`gamma(x)`	Interpolation of the factorial of `x - 1`. Fractional inputs are allowed.
`gcd(x, y)`	Computes the greatest common divisor of `x` and `y`.
`greatest_common_divisor(x, y)`	Computes the greatest common divisor of `x` and `y`.

Name	Description
`greatest(x1, x2, ...)`	Selects the largest value.
`isfinite(x)`	Returns true if the floating point value is finite, false otherwise.
`isinf(x)`	Returns true if the floating point value is infinite, false otherwise.
`isnan(x)`	Returns true if the floating point value is not a number, false otherwise.
`lcm(x, y)`	Computes the least common multiple of `x` and `y`.
`least_common_multiple(x, y)`	Computes the least common multiple of `x` and `y`.
`least(x1, x2, ...)`	Selects the smallest value.
`lgamma(x)`	Computes the log of the gamma function.
`ln(x)`	Computes the natural logarithm of `x`.
`log(x)`	Computes the base-10 logarithm of `x`.
`log10(x)`	Alias of `log`. Computes the base-10 logarithm of `x`.
`log2(x)`	Computes the base-2 log of `x`.
`multiply(x, y)`	Alias for `x * y`.
`nextafter(x, y)`	Return the next floating point value after `x` in the direction of `y`.
`pi()`	Returns the value of pi.
`pow(x, y)`	Computes `x` to the power of `y`.
`power(x, y)`	Alias of pow. Computes `x` to the power of `y`.
`radians(x)`	Converts degrees to radians.
`random()`	Returns a random number `x` in the range `0.0 <= x < 1.0`.
`round_even(v NUMERIC, s INTEGER)`	Alias of `roundbankers(v, s)`. Round to `s` decimal places using the *rounding half to even* rule. Values `s < 0` are allowed.
`roundbankers(v NUMERIC, s INTEGER)`	Alias of `round_even(v, s)`. Round to `s` decimal places using the *rounding half to even* rule. Values `s < 0` are allowed.
`round(v NUMERIC, s INTEGER)`	Round to `s` decimal places. Values `s < 0` are allowed.
`setseed(x)`	Sets the seed to be used for the random function.
`sign(x)`	Returns the sign of `x` as -1, 0 or 1.
`signbit(x)`	Returns whether the signbit is set or not.
`sin(x)`	Computes the sin of `x`.
`sqrt(x)`	Returns the square root of the number.
`subtract(x, y)`	Alias for `x - y`.
`tan(x)`	Computes the tangent of `x`.
`trunc(x)`	Truncates the number.
`xor(x, y)`	Bitwise XOR.

`@(x)`

Description	Absolute value. Parentheses are optional if `x` is a column name.
Example	`@(-17.4)`

Result	`17.4`
Alias	`abs`

`abs(x)`

Description	Absolute value.
Example	`abs(-17.4)`
Result	`17.4`
Alias	`@`

`acos(x)`

Description	Computes the inverse cosine of `x`.
Example	`acos(0.5)`
Result	`1.0471975511965976`

`acosh(x)`

Description	Computes the inverse hyperbolic cosine of `x`.
Example	`acosh(1.5)`
Result	`0.9624236501192069`

`add(x, y)`

Description	Alias for `x + y`.
Example	`add(2, 3)`
Result	`5`

`asin(x)`

Description	Computes the inverse sine of `x`.
Example	`asin(0.5)`
Result	`0.5235987755982989`

`asinh(x)`

Description	Computes the inverse hyperbolic sine of `x`.
Example	`asinh(0.5)`
Result	`0.48121182505960347`

atan(x)

Description	Computes the inverse tangent of x.
Example	`atan(0.5)`
Result	`0.4636476090008061`

atanh(x)

Description	Computes the inverse hyperbolic tangent of x.
Example	`atanh(0.5)`
Result	`0.5493061443340549`

atan2(y, x)

Description	Computes the inverse tangent (y, x).
Example	`atan2(0.5, 0.5)`
Result	`0.7853981633974483`

bit_count(x)

Description	Returns the number of bits that are set.
Example	`bit_count(31)`
Result	`5`

cbrt(x)

Description	Returns the cube root of the number.
Example	`cbrt(8)`
Result	`2`

ceil(x)

Description	Rounds the number up.
Example	`ceil(17.4)`
Result	`18`

ceiling(x)

Description	Rounds the number up. Alias of `ceil`.
Example	`ceiling(17.4)`

Result	18

cos(x)

Description	Computes the cosine of x.
Example	`cos(pi() / 3)`
Result	`0.5000000000000001`

cot(x)

Description	Computes the cotangent of x.
Example	`cot(0.5)`
Result	`1.830487721712452`

degrees(x)

Description	Converts radians to degrees.
Example	`degrees(pi())`
Result	`180`

divide(x, y)

Description	Alias for `x // y`.
Example	`divide(5, 2)`
Result	2

even(x)

Description	Round to next even number by rounding away from zero.
Example	`even(2.9)`
Result	4

exp(x)

Description	Computes `e ** x`.
Example	`exp(0.693)`
Result	2

`factorial(x)`

Description	See the `!` operator. Computes the product of the current integer and all integers below it.
Example	`factorial(4)`
Result	`24`

`fdiv(x, y)`

Description	Performs integer division (`x // y`) but returns a DOUBLE value.
Example	`fdiv(5, 2)`
Result	`2.0`

`floor(x)`

Description	Rounds the number down.
Example	`floor(17.4)`
Result	`17`

`fmod(x, y)`

Description	Calculates the modulo value. Always returns a DOUBLE value.
Example	`fmod(5, 2)`
Result	`1.0`

`gamma(x)`

Description	Interpolation of the factorial of `x - 1`. Fractional inputs are allowed.
Example	`gamma(5.5)`
Result	`52.34277778455352`

`gcd(x, y)`

Description	Computes the greatest common divisor of `x` and `y`.
Example	`gcd(42, 57)`
Result	`3`

`greatest_common_divisor(x, y)`

Description	Computes the greatest common divisor of `x` and `y`.
Example	`greatest_common_divisor(42, 57)`

Result	3

`greatest(x1, x2, ...)`

Description	Selects the largest value.
Example	`greatest(3, 2, 4, 4)`
Result	4

`isfinite(x)`

Description	Returns true if the floating point value is finite, false otherwise.
Example	`isfinite(5.5)`
Result	`true`

`isinf(x)`

Description	Returns true if the floating point value is infinite, false otherwise.
Example	`isinf('Infinity'::float)`
Result	`true`

`isnan(x)`

Description	Returns true if the floating point value is not a number, false otherwise.
Example	`isnan('NaN'::float)`
Result	`true`

`lcm(x, y)`

Description	Computes the least common multiple of x and y.
Example	`lcm(42, 57)`
Result	798

`least_common_multiple(x, y)`

Description	Computes the least common multiple of x and y.
Example	`least_common_multiple(42, 57)`
Result	798

least(x1, x2, ...)

Description	Selects the smallest value.
Example	`least(3, 2, 4, 4)`
Result	`2`

lgamma(x)

Description	Computes the log of the gamma function.
Example	`lgamma(2)`
Result	`0`

ln(x)

Description	Computes the natural logarithm of `x`.
Example	`ln(2)`
Result	`0.693`

log(x)

Description	Computes the base-10 log of `x`.
Example	`log(100)`
Result	`2`

log10(x)

Description	Alias of `log`. Computes the base-10 log of `x`.
Example	`log10(1000)`
Result	`3`

log2(x)

Description	Computes the base-2 log of `x`.
Example	`log2(8)`
Result	`3`

multiply(x, y)

Description	Alias for `x * y`.
Example	`multiply(2, 3)`

Result	6

`nextafter(x, y)`

Description	Return the next floating point value after x in the direction of y.
Example	`nextafter(1::float, 2::float)`
Result	`1.0000001`

`pi()`

Description	Returns the value of pi.
Example	`pi()`
Result	`3.141592653589793`

`pow(x, y)`

Description	Computes x to the power of y.
Example	`pow(2, 3)`
Result	8

`power(x, y)`

Description	Alias of pow. Computes x to the power of y.
Example	`power(2, 3)`
Result	8

`radians(x)`

Description	Converts degrees to radians.
Example	`radians(90)`
Result	`1.5707963267948966`

`random()`

Description	Returns a random number x in the range `0.0 <= x < 1.0`.
Example	`random()`
Result	various

`round_even(v NUMERIC, s INTEGER)`

Description	Alias of `roundbankers(v, s)`. Round to `s` decimal places using the *rounding half to even* rule. Values `s < 0` are allowed.
Example	`round_even(24.5, 0)`
Result	`24.0`

`roundbankers(v NUMERIC, s INTEGER)`

Description	Alias of `round_even(v, s)`. Round to `s` decimal places using the *rounding half to even* rule. Values `s < 0` are allowed.
Example	`roundbankers(24.5, 0)`
Result	`24.0`

`round(v NUMERIC, s INTEGER)`

Description	Round to `s` decimal places. Values `s < 0` are allowed.
Example	`round(42.4332, 2)`
Result	`42.43`

`setseed(x)`

Description	Sets the seed to be used for the random function.
Example	`setseed(0.42)`

`sign(x)`

Description	Returns the sign of `x` as -1, 0 or 1.
Example	`sign(-349)`
Result	`-1`

`signbit(x)`

Description	Returns whether the signbit is set or not.
Example	`signbit(-1.0)`
Result	`true`

`sin(x)`

Description	Computes the sin of `x`.
Example	`sin(pi() / 6)`

Result	`0.49999999999999994`

`sqrt(x)`

Description	Returns the square root of the number.
Example	`sqrt(9)`
Result	`3`

`subtract(x, y)`

Description	Alias for `x - y`.
Example	`subtract(2, 3)`
Result	`-1`

`tan(x)`

Description	Computes the tangent of `x`.
Example	`tan(pi() / 4)`
Result	`0.9999999999999999`

`trunc(x)`

Description	Truncates the number.
Example	`trunc(17.4)`
Result	`17`

`xor(x, y)`

Description	Bitwise XOR.
Example	`xor(17, 5)`
Result	`20`

Pattern Matching

There are four separate approaches to pattern matching provided by DuckDB: the traditional SQL `LIKE` operator, the more recent `SIMILAR TO` operator (added in SQL:1999), a `GLOB` operator, and POSIX-style regular expressions.

LIKE

The `LIKE` expression returns `true` if the string matches the supplied pattern. (As expected, the `NOT LIKE` expression returns `false` if `LIKE` returns `true`, and vice versa. An equivalent expression is `NOT (string LIKE pattern)`.)

If pattern does not contain percent signs or underscores, then the pattern only represents the string itself; in that case `LIKE` acts like the equals operator. An underscore (_) in pattern stands for (matches) any single character; a percent sign (%) matches any sequence of zero or more characters.

`LIKE` pattern matching always covers the entire string. Therefore, if it's desired to match a sequence anywhere within a string, the pattern must start and end with a percent sign.

Some examples:

```
SELECT 'abc' LIKE 'abc';     -- true
SELECT 'abc' LIKE 'a%' ;     -- true
SELECT 'abc' LIKE '_b_';     -- true
SELECT 'abc' LIKE 'c';       -- false
SELECT 'abc' LIKE 'c%' ;     -- false
SELECT 'abc' LIKE '%c';      -- true
SELECT 'abc' NOT LIKE '%c'; -- false
```

The keyword `ILIKE` can be used instead of `LIKE` to make the match case-insensitive according to the active locale:

```
SELECT 'abc' ILIKE '%C'; -- true
```

```
SELECT 'abc' NOT ILIKE '%C'; -- false
```

To search within a string for a character that is a wildcard (% or _), the pattern must use an `ESCAPE` clause and an escape character to indicate the wildcard should be treated as a literal character instead of a wildcard. See an example below.

Additionally, the function `like_escape` has the same functionality as a `LIKE` expression with an `ESCAPE` clause, but using function syntax. See the Text Functions page for details.

Search for strings with 'a' then a literal percent sign then 'c':

```
SELECT 'a%c' LIKE 'a$%c' ESCAPE '$'; -- true
SELECT 'azc' LIKE 'a$%c' ESCAPE '$'; -- false
```

Case-insensitive `ILIKE` with ESCAPE:

```
SELECT 'A%c' ILIKE 'a$%c' ESCAPE '$'; -- true
```

There are also alternative characters that can be used as keywords in place of `LIKE` expressions. These enhance PostgreSQL compatibility.

PostgreSQL-style	LIKE-style
`~~`	`LIKE`
`!~~`	`NOT LIKE`
`~~*`	`ILIKE`
`!~~*`	`NOT ILIKE`

SIMILAR TO

The `SIMILAR TO` operator returns true or false depending on whether its pattern matches the given string. It is similar to `LIKE`, except that it interprets the pattern using a regular expression. Like `LIKE`, the `SIMILAR TO` operator succeeds only if its pattern matches the entire string; this is unlike common regular expression behavior where the pattern can match any part of the string.

A regular expression is a character sequence that is an abbreviated definition of a set of strings (a regular set). A string is said to match a regular expression if it is a member of the regular set described by the regular expression. As with `LIKE`, pattern characters match string characters exactly unless they are special characters in the regular expression language — but regular expressions use different special characters than `LIKE` does.

Some examples:

```
SELECT 'abc' SIMILAR TO 'abc';       -- true
SELECT 'abc' SIMILAR TO 'a';         -- false
SELECT 'abc' SIMILAR TO '.*(b|d).*'; -- true
SELECT 'abc' SIMILAR TO '(b|c).*';   -- false
SELECT 'abc' NOT SIMILAR TO 'abc';   -- false
```

> In PostgreSQL, `~` is equivalent to `SIMILAR TO` and `!~` is equivalent to `NOT SIMILAR TO`. In DuckDB, these equivalences do not hold currently, see the PostgreSQL compatibility page.

Globbing

DuckDB supports file name expansion, also known as globbing, for discovering files. DuckDB's glob syntax uses the question mark (`?`) wildcard to match any single character and the asterisk (`*`) to match zero or more characters. In addition, you can use the bracket syntax (`[...]`) to match any single character contained within the brackets, or within the character range specified by the brackets. An exclamation mark (`!`) may be used inside the first bracket to search for a character that is not contained within the brackets. To learn more, visit the "glob (programming)" Wikipedia page.

GLOB

The `GLOB` operator returns `true` or `false` if the string matches the `GLOB` pattern. The `GLOB` operator is most commonly used when searching for filenames that follow a specific pattern (for example a specific file extension).

Some examples:

```
SELECT 'best.txt' GLOB '*.txt';            -- true
SELECT 'best.txt' GLOB '????.txt';         -- true
SELECT 'best.txt' GLOB '?.txt';            -- false
SELECT 'best.txt' GLOB '[abc]est.txt';     -- true
SELECT 'best.txt' GLOB '[a-z]est.txt';     -- true
```

The bracket syntax is case-sensitive:

```
SELECT 'Best.txt' GLOB '[a-z]est.txt';     -- false
SELECT 'Best.txt' GLOB '[a-zA-Z]est.txt';  -- true
```

The `!` applies to all characters within the brackets:

```
SELECT 'Best.txt' GLOB '[!a-zA-Z]est.txt'; -- false
```

To negate a GLOB operator, negate the entire expression:

```
SELECT NOT 'best.txt' GLOB '*.txt';        -- false
```

Three tildes (~~~) may also be used in place of the `GLOB` keyword.

GLOB-style	Symbolic-style
GLOB	~~~

Glob Function to Find Filenames

The glob pattern matching syntax can also be used to search for filenames using the `glob` table function. It accepts one parameter: the path to search (which may include glob patterns).

Search the current directory for all files:

```
SELECT * FROM glob('*');
```

file
duckdb.exe
test.csv
test.json
test.parquet
test2.csv
test2.parquet
todos.json

Globbing Semantics

DuckDB's globbing implementation follows the semantics of Python's `glob` and not the `glob` used in the shell. A notable difference is the behavior of the `**/` construct: `**/<filename>{:.language-sql .highlight}` will not return a file with `<filename>{:.language-sql .highlight}` in top-level directory. For example, with a `README.md` file present in the directory, the following query finds it:

```
SELECT * FROM glob('README.md');
```

file
README.md

However, the following query returns an empty result:

```
SELECT * FROM glob('**/README.md');
```

Meanwhile, the globbing of Bash, Zsh, etc. finds the file using the same syntax:

```
ls **/README.md
```

```
README.md
```

Regular Expressions

DuckDB's regular expression support is documented on the Regular Expressions page. DuckDB supports some PostgreSQL-style operators for regular expression matching:

PostgreSQL-style	Equivalent expression
`~`	`regexp_full_match`
`!~`	NOT `regexp_full_match`
`~*`	(not supported)

PostgreSQL-style	Equivalent expression
`!~*`	(not supported)

Regular Expressions

DuckDB offers pattern matching operators (`LIKE`, `SIMILAR TO`, `GLOB`), as well as support for regular expressions via functions.

Regular Expression Syntax

DuckDB uses the RE2 library as its regular expression engine. For the regular expression syntax, see the RE2 docs.

Functions

All functions accept an optional set of options.

Name	Description
`regexp_extract(string, pattern[, group = 0][, options])`	If `string` contains the regexp `pattern`, returns the capturing group specified by optional parameter `group`; otherwise, returns the empty string. The `group` must be a constant value. If no `group` is given, it defaults to 0. A set of optional `options` can be set.
`regexp_extract(string, pattern, name_list[, options])`	If `string` contains the regexp `pattern`, returns the capturing groups as a struct with corresponding names from `name_list`; otherwise, returns a struct with the same keys and empty strings as values.
`regexp_extract_all(string, regex[, group = 0][, options])`	Finds non-overlapping occurrences of `regex` in `string` and returns the corresponding values of `group`.
`regexp_extract_all(string, regex, name_list[, options])`	Finds non-overlapping occurrences of `regex` in `string` and returns the capturing groups as a list of structs with corresponding names from `name_list`.
`regexp_full_match(string, regex[, options])`	Returns `true` if the entire `string` matches the `regex`.
`regexp_matches(string, pattern[, options])`	Returns `true` if `string` contains the regexp `pattern`, `false` otherwise.
`regexp_replace(string, pattern, replacement[, options])`	If `string` contains the regexp `pattern`, replaces the matching part with `replacement`. By default, only the first occurrence is replaced. A set of optional `options`, including the global flag `g`, can be set.
`regexp_split_to_array(string, regex[, options])`	Alias of `string_split_regex`. Splits the `string` along the `regex`.
`regexp_split_to_table(string, regex[, options])`	Splits the `string` along the `regex` and returns a row for each part.

`regexp_extract(string, pattern[, group = 0][, options])`

Description	If `string` contains the regexp `pattern`, returns the capturing group specified by optional parameter `group`; otherwise, returns the empty string. The `group` must be a constant value. If no `group` is given, it defaults to 0. A set of optional `options` can be set.
Example	`regexp_extract('abc', '([a-z])(b)', 1)`
Result	a

`regexp_extract(string, pattern, name_list[, options])`

Description	If `string` contains the regexp `pattern`, returns the capturing groups as a struct with corresponding names from `name_list`; otherwise, returns a struct with the same keys and empty strings as values. A set of optional `options` can be set.
Example	`regexp_extract('2023-04-15', '(\d+)-(\d+)-(\d+)', ['y', 'm', 'd'])`
Result	`{'y':'2023', 'm':'04', 'd':'15'}`

`regexp_extract_all(string, regex[, group = 0][, options])`

Description	Finds non-overlapping occurrences of `regex` in `string` and returns the corresponding values of `group`. A set of optional `options` can be set.
Example	`regexp_extract_all('Peter: 33, Paul:14', '(\w+):\s*(\d+)', 2)`
Result	`[33, 14]`

`regexp_extract_all(string, regex, name_list[, options])`

Description	Finds non-overlapping occurrences of `regex` in `string` and returns the capturing groups as a list of structs with corresponding names from `name_list`. A set of optional `options` can be set.
Example	`regexp_extract_all('Peter: 33, Paul: 14', '(\w+):\s*(\d+)', ['name', 'age'])`
Result	`[{'name': Peter, 'age': 33}, {'name': Paul, 'age': 14}]`

`regexp_full_match(string, regex[, options])`

Description	Returns `true` if the entire `string` matches the `regex`. A set of optional `options` can be set.
Example	`regexp_full_match('anabanana', '(an)*')`
Result	`false`

`regexp_matches(string, pattern[, options])`

Description	Returns `true` if `string` contains the regexp `pattern`, `false` otherwise. A set of optional `options` can be set.
Example	`regexp_matches('anabanana', '(an)*')`
Result	`true`

`regexp_replace(string, pattern, replacement[, options])`

Description	If `string` contains the regexp `pattern`, replaces the matching part with `replacement`. By default, only the first occurrence is replaced. A set of optional `options`, including the global flag `g`, can be set.
Example	`regexp_replace('hello', '[lo]', '-')`
Result	`he-lo`

`regexp_split_to_array(string, regex[, options])`

Description	Alias of `string_split_regex`. Splits the `string` along the `regex`. A set of optional `options` can be set.
Example	`regexp_split_to_array('hello world; 42', ';? ')`
Result	`['hello', 'world', '42']`

`regexp_split_to_table(string, regex[, options])`

Description	Splits the `string` along the `regex` and returns a row for each part. A set of optional `options` can be set.
Example	`regexp_split_to_table('hello world; 42', ';? ')`
Result	Three rows: `'hello'`, `'world'`, `'42'`

The `regexp_matches` function is similar to the `SIMILAR TO` operator, however, it does not require the entire string to match. Instead, `regexp_matches` returns `true` if the string merely contains the pattern (unless the special tokens `^` and `$` are used to anchor the regular expression to the start and end of the string). Below are some examples:

```
SELECT regexp_matches('abc', 'abc');       -- true
SELECT regexp_matches('abc', '^abc$');     -- true
SELECT regexp_matches('abc', 'a');         -- true
SELECT regexp_matches('abc', '^a$');       -- false
SELECT regexp_matches('abc', '.*(b|d).*'); -- true
SELECT regexp_matches('abc', '(b|c).*');   -- true
SELECT regexp_matches('abc', '^(b|c).*');  -- false
SELECT regexp_matches('abc', '(?i)A');     -- true
SELECT regexp_matches('abc', 'A', 'i');    -- true
```

Options for Regular Expression Functions

The regex functions support the following `options`.

Option	Description
`'c'`	Case-sensitive matching
`'i'`	Case-insensitive matching
`'l'`	Match literals instead of regular expression tokens
`'m'`, `'n'`, `'p'`	Newline sensitive matching
`'g'`	Global replace, only available for `regexp_replace`

Option	Description
's'	Non-newline sensitive matching

For example:

```
SELECT regexp_matches('abcd', 'ABC', 'c'); -- false
SELECT regexp_matches('abcd', 'ABC', 'i'); -- true
SELECT regexp_matches('ab^/$cd', '^/$', 'l'); -- true
SELECT regexp_matches(E'hello\nworld', 'hello.world', 'p'); -- false
SELECT regexp_matches(E'hello\nworld', 'hello.world', 's'); -- true
```

Using `regexp_matches`

The `regexp_matches` operator will be optimized to the `LIKE` operator when possible. To achieve best performance, the `'c'` option (case-sensitive matching) should be passed if applicable. Note that by default the RE2 library doesn't match the `.` character to newline.

Original	Optimized equivalent
`regexp_matches('hello world', '^hello', 'c')`	`prefix('hello world', 'hello')`
`regexp_matches('hello world', 'world$', 'c')`	`suffix('hello world', 'world')`
`regexp_matches('hello world', 'hello.world', 'c')`	`LIKE 'hello_world'`
`regexp_matches('hello world', 'he.*rld', 'c')`	`LIKE '%he%rld'`

Using `regexp_replace`

The `regexp_replace` function can be used to replace the part of a string that matches the regexp pattern with a replacement string. The notation \d (where d is a number indicating the group) can be used to refer to groups captured in the regular expression in the replacement string. Note that by default, `regexp_replace` only replaces the first occurrence of the regular expression. To replace all occurrences, use the global replace (g) flag.

Some examples for using `regexp_replace`:

```
SELECT regexp_replace('abc', '(b|c)', 'X');        -- aXc
SELECT regexp_replace('abc', '(b|c)', 'X', 'g');   -- aXX
SELECT regexp_replace('abc', '(b|c)', '\1\1\1\1'); -- abbbbc
SELECT regexp_replace('abc', '(.*)c', '\1e');      -- abe
SELECT regexp_replace('abc', '(a)(b)', '\2\1');    -- bac
```

Using `regexp_extract`

The `regexp_extract` function is used to extract a part of a string that matches the regexp pattern. A specific capturing group within the pattern can be extracted using the `group` parameter. If `group` is not specified, it defaults to 0, extracting the first match with the whole pattern.

```
SELECT regexp_extract('abc', '.b.');           -- abc
SELECT regexp_extract('abc', '.b.', 0);        -- abc
SELECT regexp_extract('abc', '.b.', 1);        -- (empty)
SELECT regexp_extract('abc', '([a-z])(b)', 1); -- a
SELECT regexp_extract('abc', '([a-z])(b)', 2); -- b
```

The `regexp_extract` function also supports a `name_list` argument, which is a `LIST` of strings. Using `name_list`, the `regexp_extract` will return the corresponding capture groups as fields of a `STRUCT`:

```
SELECT regexp_extract('2023-04-15', '(\d+)-(\d+)-(\d+)', ['y', 'm', 'd']);
```

```
{'y': 2023, 'm': 04, 'd': 15}
```

```
SELECT regexp_extract('2023-04-15 07:59:56', '^(\d+)-(\d+)-(\d+) (\d+):(\d+):(\d+)', ['y', 'm', 'd']);
```

```
{'y': 2023, 'm': 04, 'd': 15}
```

```
SELECT regexp_extract('duckdb_0_7_1', '^(\w+)_(\d+)_(\d+)', ['tool', 'major', 'minor', 'fix']);
```

```
Binder Error:
Not enough group names in regexp_extract
```

If the number of column names is less than the number of capture groups, then only the first groups are returned. If the number of column names is greater, then an error is generated.

Limitations

Regular expressions only support 9 capture groups: `\1`, `\2`, `\3`, ..., `\9`. Capture groups with two or more digits are not supported.

Struct Functions

Name	Description
`struct.entry`	Dot notation that serves as an alias for `struct_extract` from named STRUCTs.
`struct[entry]`	Bracket notation that serves as an alias for `struct_extract` from named STRUCTs.
`struct[idx]`	Bracket notation that serves as an alias for `struct_extract` from unnamed STRUCTs (tuples), using an index (1-based).
`row(any, ...)`	Create an unnamed STRUCT (tuple) containing the argument values.
`struct_concat(structs...)`	Merge the multiple `structs` into a single STRUCT.
`struct_contains(struct, entry)`	Check if the STRUCT contains the specified entry.
`struct_extract(struct, 'entry')`	Extract the named entry from the STRUCT.
`struct_extract(struct, idx)`	Extract the entry from an unnamed STRUCT (tuple) using an index (1-based).
`struct_extract_at(struct, idx)`	Extract the entry from a STRUCT (tuple) using an index (1-based).
`struct_insert(struct, name := any, ...)`	Add field(s) to an existing STRUCT.
`struct_pack(name := any, ...)`	Create a STRUCT containing the argument values. The entry name will be the bound variable name.
`struct_position(struct, entry)`	Return the index of the entry within the STRUCT (1-based), or `NULL` if not found.
`struct_update(struct, name := any, ...)`	Add or update field(s) of an existing STRUCT.
`struct_values(struct)`	Return the values of a STRUCT as an unnamed STRUCT (tuple).

`struct.entry`

Description	Dot notation that serves as an alias for `struct_extract` from named STRUCTs.
Example	`({'i': 3, 's': 'string'}).i`
Result	3

`struct[entry]`

Description	Bracket notation that serves as an alias for `struct_extract` from named STRUCTs.
Example	`({'i': 3, 's': 'string'})['i']`
Result	3

`struct[idx]`

Description	Bracket notation that serves as an alias for `struct_extract` from unnamed STRUCTs (tuples), using an index (1-based).
Example	`(row(42, 84))[1]`
Result	42

`row(any, ...)`

Description	Create an unnamed STRUCT (tuple) containing the argument values.
Example	`row(i, i % 4, i / 4)`
Result	`(10, 2, 2.5)`

`struct_concat(structs...)`

Description	Merge the multiple `structs` into a single STRUCT.
Example	`struct_concat(struct_pack(i := 4), struct_pack(s := 'string'))`
Result	`{'i': 4, 's': string}`

`struct_contains(struct, entry)`

Description	Check if the STRUCT contains the specified entry.
Example	`struct_contains(row(1, 2, 3), 2)`
Result	`true`
Alias	`struct_has`

`struct_extract(struct, 'entry')`

Description	Extract the named entry from the STRUCT.
Example	`struct_extract({'i': 3, 'v2': 3, 'v3': 0}, 'i')`
Result	3

`struct_extract(struct, idx)`

Description	Extract the entry from an unnamed STRUCT (tuple) using an index (1-based).
Example	`struct_extract(row(42, 84), 1)`
Result	42

`struct_extract_at(struct, idx)`

Description	Extract the entry from a STRUCT (tuple) using an index (1-based).
Example	`struct_extract_at({'v1': 10, 'v2': 20, 'v3': 3}, 20)`
Result	20

`struct_insert(struct, name := any, ...)`

Description	Add field(s) to an existing STRUCT.
Example	`struct_insert({'a': 1}, b := 2)`
Result	`{'a': 1, 'b': 2}`

`struct_pack(name := any, ...)`

Description	Create a STRUCT containing the argument values. The entry name will be the bound variable name.
Example	`struct_pack(i := 4, s := 'string')`
Result	`{'i': 4, 's': string}`

`struct_position(struct, entry)`

Description	Return the index of the entry within the STRUCT (1-based), or `NULL` if not found.
Example	`struct_position(row(1, 2, 3), 2)`
Result	2
Alias	`struct_indexof`

`struct_update(struct, name := any, ...)`

Description	Add or update field(s) of an existing STRUCT.
Example	`struct_update({'a': 1, 'b': 2}, b := 3, c := 4)`

Result	`{'a': 1, 'b': 3, 'c': 4}`

`struct_values(struct)`

Description	Return the values of a STRUCT as an unnamed STRUCT (tuple).
Example	`struct_values({'a': 1, 'b': 2, 'c': 3})`
Result	`(1, 2, 3)`

Text Functions

Text Functions and Operators

This section describes functions and operators for examining and manipulating `STRING` values.

Function	Description
`string[index]`	Extracts a single character using a (1-based) `index`.
`string[begin:end]`	Extracts a string using slice conventions similar to Python. Missing `begin` or `end` arguments are interpreted as the beginning or end of the list respectively. Negative values are accepted.
`string LIKE target`	Returns `true` if the `string` matches the like specifier (see Pattern Matching).
`string SIMILAR TO regex`	Returns `true` if the `string` matches the `regex` (see Pattern Matching).
`string ^@ search_string`	Alias for `starts_with`.
`arg1 || arg2`	Concatenates two strings, lists, or blobs. Any `NULL` input results in `NULL`. See also `concat(arg1, arg2, ...)` and `list_concat(list1, list2, ...)`.
`array_extract(string, index)`	Extracts a single character from a `string` using a (1-based) `index`.
`array_slice(list, begin, end)`	Extracts a sublist or substring using slice conventions. Negative values are accepted.
`ascii(string)`	Returns an integer that represents the Unicode code point of the first character of the `string`.
`bar(x, min, max[, width])`	Draws a band whose width is proportional to (`x - min`) and equal to `width` characters when `x` = `max`. `width` defaults to 80.
`base64(blob)`	Alias for `to_base64`.
`bin(string)`	Converts the `string` to binary representation.
`bit_length(string)`	Number of bits in a `string`.
`char_length(string)`	Alias for `length`.
`character_length(string)`	Alias for `length`.
`chr(code_point)`	Returns a character which is corresponding the ASCII code value or Unicode code point.
`concat(value, ...)`	Concatenates multiple strings or lists. `NULL` inputs are skipped. See also operator `||`.
`concat_ws(separator, string, ...)`	Concatenates many strings, separated by `separator`. `NULL` inputs are skipped.
`contains(string, search_string)`	Returns `true` if `search_string` is found within `string`. Note that collations are not supported.

Function	Description
`ends_with(string, search_string)`	Alias for `suffix`.
`format(format, ...)`	Formats a string using the fmt syntax.
`formatReadableDecimalSize(integer)`	Converts `integer` to a human-readable representation using units based on powers of 10 (KB, MB, GB, etc.).
`format_bytes(integer)`	Converts `integer` to a human-readable representation using units based on powers of 2 (KiB, MiB, GiB, etc.).
`from_base64(string)`	Converts a base64 encoded `string` to a character string (`BLOB`).
`from_binary(value)`	Alias for `unbin`.
`from_hex(value)`	Alias for `unhex`.
`greatest(arg1, ...)`	Returns the largest value in lexicographical order. Note that lowercase characters are considered larger than uppercase characters and collations are not supported.
`hash(value, ...)`	Returns a `UBIGINT` with the hash of the `value`. Note that this is not a cryptographic hash.
`hex(string)`	Converts the `string` to hexadecimal representation.
`ilike_escape(string, like_specifier, escape_character)`	Returns `true` if the `string` matches the `like_specifier` (see Pattern Matching) using case-insensitive matching. `escape_character` is used to search for wildcard characters in the `string`.
`instr(string, search_string)`	Returns location of first occurrence of `search_string` in `string`, counting from 1. Returns 0 if no match found.
`lcase(string)`	Alias for `lower`.
`least(arg1, ...)`	Returns the smallest value in lexicographical order. Note that uppercase characters are considered smaller than lowercase characters and collations are not supported.
`left(string, count)`	Extracts the left-most count characters.
`left_grapheme(string, count)`	Extracts the left-most count grapheme clusters.
`len(string)`	Alias for `length`.
`length(string)`	Number of characters in `string`.
`length_grapheme(string)`	Number of grapheme clusters in `string`.
`like_escape(string, like_specifier, escape_character)`	Returns `true` if the `string` matches the `like_specifier` (see Pattern Matching) using case-sensitive matching. `escape_character` is used to search for wildcard characters in the `string`.
`lower(string)`	Converts `string` to lower case.
`lpad(string, count, character)`	Pads the `string` with the `character` on the left until it has `count` characters. Truncates the `string` on the right if it has more than `count` characters.
`ltrim(string[, characters])`	Removes any occurrences of any of the `characters` from the left side of the `string`. `characters` defaults to `space`.
`md5(string)`	Returns the MD5 hash of the `string` as a `VARCHAR`.
`md5_number(string)`	Returns the MD5 hash of the `string` as a `HUGEINT`.
`md5_number_lower(string)`	Returns the lower 64-bit segment of the MD5 hash of the `string` as a `UBIGINT`.
`md5_number_upper(string)`	Returns the upper 64-bit segment of the MD5 hash of the `string` as a `UBIGINT`.
`nfc_normalize(string)`	Converts `string` to Unicode NFC normalized string. Useful for comparisons and ordering if text data is mixed between NFC normalized and not.

Function	Description
`not_ilike_escape(string, like_specifier, escape_character)`	Returns `false` if the `string` matches the `like_specifier` (see Pattern Matching) using case-insensitive matching. `escape_character` is used to search for wildcard characters in the `string`.
`not_like_escape(string, like_specifier, escape_character)`	Returns `false` if the `string` matches the `like_specifier` (see Pattern Matching) using case-sensitive matching. `escape_character` is used to search for wildcard characters in the `string`.
`ord(string)`	Alias for `unicode`.
`parse_dirname(path[, separator])`	Returns the top-level directory name from the given `path`. `separator` options: `system`, `both_slash` (default), `forward_slash`, `backslash`.
`parse_dirpath(path[, separator])`	Returns the head of the `path` (the pathname until the last slash) similarly to Python's `os.path.dirname`. `separator` options: `system`, `both_slash` (default), `forward_slash`, `backslash`.
`parse_filename(string[, trim_extension][, separator])`	Returns the last component of the `path` similarly to Python's `os.path.basename` function. If `trim_extension` is `true`, the file extension will be removed (defaults to `false`). `separator` options: `system`, `both_slash` (default), `forward_slash`, `backslash`.
`parse_path(path[, separator])`	Returns a list of the components (directories and filename) in the `path` similarly to Python's `pathlib.parts` function. `separator` options: `system`, `both_slash` (default), `forward_slash`, `backslash`.
`position(search_string IN string)`	Return location of first occurrence of `search_string` in `string`, counting from 1. Returns 0 if no match found.
`position(string, search_string)`	Alias for `instr`.
`prefix(string, search_string)`	Returns `true` if `string` starts with `search_string`.
`printf(format, ...)`	Formats a `string` using printf syntax.
`read_text(source)`	Returns the content from `source` (a filename, a list of filenames, or a glob pattern) as a VARCHAR. The file content is first validated to be valid UTF-8. If `read_text` attempts to read a file with invalid UTF-8 an error is thrown suggesting to use `read_blob` instead. See the `read_text` guide for more details.
`regexp_escape(string)`	Escapes special patterns to turn `string` into a regular expression similarly to Python's `re.escape` function.
`regexp_extract(string, regex[, group][, options])`	If `string` contains the `regex` pattern, returns the capturing group specified by optional parameter `group`; otherwise, returns the empty string. The `group` must be a constant value. If no `group` is given, it defaults to 0. A set of optional regex `options` can be set.
`regexp_extract(string, regex, name_list[, options])`	If `string` contains the `regex` pattern, returns the capturing groups as a struct with corresponding names from `name_list`; otherwise, returns a struct with the same keys and empty strings as values. A set of optional regex `options` can be set.
`regexp_extract_all(string, regex[, group][, options])`	Finds non-overlapping occurrences of the `regex` in the `string` and returns the corresponding values of the capturing `group`. A set of optional regex `options` can be set.
`regexp_extract_all(string, regex, name_list[, options])`	Finds non-overlapping occurrences of `regex` in `string` and returns the capturing groups as a list of structs with corresponding names from `name_list`. A set of optional regex `options` can be set.
`regexp_full_match(string, regex[, col2])`	Returns `true` if the entire `string` matches the `regex`. A set of optional regex `options` can be set.

Function	Description
`regexp_matches(string, regex[, options])`	Returns `true` if `string` contains the `regex`, `false` otherwise. A set of optional regex `options` can be set.
`regexp_replace(string, regex, replacement[, options])`	If `string` contains the `regex`, replaces the matching part with `replacement`. A set of optional regex `options` can be set.
`regexp_split_to_array(string, regex[, options])`	Alias for `string_split_regex`.
`regexp_split_to_table(string, regex)`	Splits the `string` along the `regex` and returns a row for each part.
`repeat(string, count)`	Repeats the `string` `count` number of times.
`replace(string, source, target)`	Replaces any occurrences of the `source` with `target` in `string`.
`reverse(string)`	Reverses the `string`.
`right(string, count)`	Extract the right-most `count` characters.
`right_grapheme(string, count)`	Extracts the right-most `count` grapheme clusters.
`rpad(string, count, character)`	Pads the `string` with the `character` on the right until it has `count` characters. Truncates the `string` on the right if it has more than `count` characters.
`rtrim(string[, characters])`	Removes any occurrences of any of the `characters` from the right side of the `string`. `characters` defaults to `space`.
`sha1(value)`	Returns a VARCHAR with the SHA-1 hash of the `value`.
`sha256(value)`	Returns a VARCHAR with the SHA-256 hash of the `value`.
`split(string, separator)`	Alias for `string_split`.
`split_part(string, separator, index)`	Splits the `string` along the `separator` and returns the data at the (1-based) `index` of the list. If the `index` is outside the bounds of the list, return an empty string (to match PostgreSQL's behavior).
`starts_with(string, search_string)`	Returns `true` if `string` begins with `search_string`.
`str_split(string, separator)`	Alias for `string_split`.
`str_split_regex(string, regex[, options])`	Alias for `string_split_regex`.
`string_split(string, separator)`	Splits the `string` along the `separator`.
`string_split_regex(string, regex[, options])`	Splits the `string` along the `regex`. A set of optional regex `options` can be set.
`string_to_array(string, separator)`	Alias for `string_split`.
`strip_accents(string)`	Strips accents from `string`.
`strlen(string)`	Number of bytes in `string`.
`strpos(string, search_string)`	Alias for `instr`.

Function	Description
`substr(string, start[, length])`	Alias for `substring`.
`substring(string, start[, length])`	Extracts substring starting from character `start` up to the end of the string. If optional argument `length` is set, extracts a substring of `length` characters instead. Note that a `start` value of `1` refers to the first character of the `string`.
`substring_grapheme(string, start[, length])`	Extracts substring starting from grapheme clusters `start` up to the end of the string. If optional argument `length` is set, extracts a substring of `length` grapheme clusters instead. Note that a `start` value of `1` refers to the `first` character of the `string`.
`suffix(string, search_string)`	Returns `true` if `string` ends with `search_string`. Note that collations are not supported.
`to_base(number, radix[, min_length])`	Converts `number` to a string in the given base `radix`, optionally padding with leading zeros to `min_length`.
`to_base64(blob)`	Converts a `blob` to a base64 encoded string.
`to_binary(string)`	Alias for `bin`.
`to_hex(string)`	Alias for `hex`.
`translate(string, from, to)`	Replaces each character in `string` that matches a character in the `from` set with the corresponding character in the `to` set. If `from` is longer than `to`, occurrences of the extra characters in `from` are deleted.
`trim(string[, characters])`	Removes any occurrences of any of the `characters` from either side of the `string`. `characters` defaults to `space`.
`ucase(string)`	Alias for `upper`.
`unbin(value)`	Converts a `value` from binary representation to a blob.
`unhex(value)`	Converts a `value` from hexadecimal representation to a blob.
`unicode(string)`	Returns an `INTEGER` representing the `unicode` codepoint of the first character in the `string`.
`upper(string)`	Converts `string` to upper case.
`url_decode(string)`	Decodes a URL from a representation using Percent-Encoding.
`url_encode(string)`	Encodes a URL to a representation using Percent-Encoding.

`string[index]`

Description	Extracts a single character using a (1-based) `index`.
Example	`'DuckDB'[4]`
Result	k
Alias	`array_extract`

`string[begin:end]`

Description	Extracts a string using slice conventions similar to Python. Missing `begin` or `end` arguments are interpreted as the beginning or end of the list respectively. Negative values are accepted.
Example	`'DuckDB'[:4]`
Result	Duck
Alias	`array_slice`

`string LIKE target`

Description	Returns `true` if the `string` matches the like specifier (see Pattern Matching).
Example	`'hello' LIKE '%lo'`
Result	`true`

`string SIMILAR TO regex`

Description	Returns `true` if the `string` matches the `regex` (see Pattern Matching).
Example	`'hello' SIMILAR TO 'l+'`
Result	`false`
Alias	`regexp_full_match`

`arg1 || arg2`

Description	Concatenates two strings, lists, or blobs. Any `NULL` input results in `NULL`. See also `concat(arg1, arg2, ...)` and `list_concat(list1, list2, ...)`.
Example 1	`'Duck' || 'DB'`
Result	DuckDB
Example 2	`[1, 2, 3] || [4, 5, 6]`
Result	`[1, 2, 3, 4, 5, 6]`
Example 3	`'\xAA'::BLOB || '\xBB'::BLOB`
Result	\xAA\xBB

`array_extract(string, index)`

Description	Extracts a single character from a `string` using a (1-based) `index`.
Example	`array_extract('DuckDB', 2)`
Result	u

`array_slice(list, begin, end)`

Description	Extracts a sublist or substring using slice conventions. Negative values are accepted.
Example 1	`array_slice('DuckDB', 3, 4)`
Result	ck
Example 2	`array_slice('DuckDB', 3, NULL)`
Result	NULL
Example 3	`array_slice('DuckDB', 0, -3)`
Result	Duck

Alias	`list_slice`

`ascii(string)`

Description	Returns an integer that represents the Unicode code point of the first character of the `string`.
Example	`ascii('Ω')`
Result	`937`

`bar(x, min, max[, width])`

Description	Draws a band whose width is proportional to (`x - min`) and equal to `width` characters when x = `max`. `width` defaults to 80.
Example	`bar(5, 0, 20, 10)`
Result	██

`bin(string)`

Description	Converts the `string` to binary representation.
Example	`bin('Aa')`
Result	`0100000101100001`
Alias	`to_binary`

`bit_length(string)`

Description	Number of bits in a `string`.
Example	`bit_length('abc')`
Result	`24`

`chr(code_point)`

Description	Returns a character which is corresponding the ASCII code value or Unicode code point.
Example	`chr(65)`
Result	A

`concat(value, ...)`

Description	Concatenates multiple strings or lists. `NULL` inputs are skipped. See also operator `||`.
Example 1	`concat('Hello', ' ', 'World')`
Result	`Hello World`

Example 2	`concat([1, 2, 3], NULL, [4, 5, 6])`
Result	`[1, 2, 3, 4, 5, 6]`

`concat_ws(separator, string, ...)`

Description	Concatenates many strings, separated by `separator`. `NULL` inputs are skipped.
Example	`concat_ws(', ', 'Banana', 'Apple', 'Melon')`
Result	`Banana, Apple, Melon`

`contains(string, search_string)`

Description	Returns `true` if `search_string` is found within `string`.
Example	`contains('abc', 'a')`
Result	`true`

`format(format, ...)`

Description	Formats a string using the fmt syntax.
Example	`format('Benchmark "{}" took {} seconds', 'CSV', 42)`
Result	`Benchmark "CSV" took 42 seconds`

`formatReadableDecimalSize(integer)`

Description	Converts `integer` to a human-readable representation using units based on powers of 10 (KB, MB, GB, etc.).
Example	`formatReadableDecimalSize(16000)`
Result	`16.0 kB`

`format_bytes(integer)`

Description	Converts `integer` to a human-readable representation using units based on powers of 2 (KiB, MiB, GiB, etc.).
Example	`format_bytes(16_000)`
Result	`15.6 KiB`
Alias	`formatReadableSize`, `pg_size_pretty`

`from_base64(string)`

Description	Converts a base64 encoded `string` to a character string (`BLOB`).
Example	`from_base64('QQ==')`

Result	A

`greatest(arg1, ...)`

Description	Returns the largest value in lexicographical order. Note that lowercase characters are considered larger than uppercase characters and collations are not supported.
Example 1	`greatest(42, 84)`
Result	`84`
Example 2	`greatest('abc', 'bcd', 'cde', 'EFG')`
Result	`cde`

`hash(value, ...)`

Description	Returns a `UBIGINT` with the hash of the `value`. Note that this is not a cryptographic hash.
Example	`hash('🦆')`
Result	`4164431626903154684`

`hex(string)`

Description	Converts the `string` to hexadecimal representation.
Example	`hex('Hello')`
Result	`48656C6C6F`
Alias	`to_hex`

`ilike_escape(string, like_specifier, escape_character)`

Description	Returns `true` if the `string` matches the `like_specifier` (see Pattern Matching) using case-insensitive matching. `escape_character` is used to search for wildcard characters in the `string`.
Example	`ilike_escape('A%c', 'a$%C', '$')`
Result	`true`

`instr(string, search_string)`

Description	Returns location of first occurrence of `search_string` in `string`, counting from 1. Returns 0 if no match found.
Example	`instr('test test', 'es')`
Result	2
Aliases	`position`, `strpos`

`least(arg1, ...)`

Description	Returns the smallest value in lexicographical order. Note that uppercase characters are considered smaller than lowercase characters and collations are not supported.
Example 1	`least(42, 84)`
Result	42
Example 2	`least('abc', 'bcd', 'cde', 'EFG')`
Result	EFG

`left(string, count)`

Description	Extracts the left-most count characters.
Example	`left('Hello🦆', 2)`
Result	He

`left_grapheme(string, count)`

Description	Extracts the left-most count grapheme clusters.
Example	`left_grapheme('👩🏻‍♂️👩🏽‍♀️', 1)`
Result	👩🏻‍♂️

`length(string)`

Description	Number of characters in `string`.
Example	`length('Hello🦆')`
Result	6
Aliases	`char_length`, `character_length`, `len`

`length_grapheme(string)`

Description	Number of grapheme clusters in `string`.
Example	`length_grapheme('👩🏻‍♂️👩🏽‍♀️')`
Result	2

`like_escape(string, like_specifier, escape_character)`

Description	Returns `true` if the `string` matches the `like_specifier` (see Pattern Matching) using case-sensitive matching. `escape_character` is used to search for wildcard characters in the `string`.
Example	`like_escape('a%c', 'a$%c', '$')`
Result	`true`

`lower(string)`

Description	Converts `string` to lower case.
Example	`lower('Hello')`
Result	`hello`
Alias	`lcase`

`lpad(string, count, character)`

Description	Pads the `string` with the `character` on the left until it has `count` characters. Truncates the `string` on the right if it has more than `count` characters.
Example	`lpad('hello', 8, '>')`
Result	`>>>hello`

`ltrim(string[, characters])`

Description	Removes any occurrences of any of the `characters` from the left side of the `string`. `characters` defaults to `space`.
Example 1	ltrim(' test ')
Result	test
Example 2	`ltrim('>>>>test<<', '><')`
Result	`test<<`

`md5(string)`

Description	Returns the MD5 hash of the `string` as a VARCHAR.
Example	`md5('abc')`
Result	`900150983cd24fb0d6963f7d28e17f72`

`md5_number(string)`

Description	Returns the MD5 hash of the `string` as a HUGEINT.
Example	`md5_number('abc')`
Result	`152195979970564155685860391459828531600`

`md5_number_lower(string)`

Description	Returns the lower 64-bit segment of the MD5 hash of the `string` as a UBIGINT.
Example	`md5_number_lower('abc')`
Result	`8250560606382298838`

`md5_number_upper(string)`

Description	Returns the upper 64-bit segment of the MD5 hash of the `string` as a `UBIGINT`.
Example	`md5_number_upper('abc')`
Result	`12704604231530709392`

`nfc_normalize(string)`

Description	Converts `string` to Unicode NFC normalized string. Useful for comparisons and ordering if text data is mixed between NFC normalized and not.
Example	`nfc_normalize('ardèch')`
Result	`ardèch`

`not_ilike_escape(string, like_specifier, escape_character)`

Description	Returns `false` if the `string` matches the `like_specifier` (see Pattern Matching) using case-insensitive matching. `escape_character` is used to search for wildcard characters in the `string`.
Example	`not_ilike_escape('A%c', 'a$%C', '$')`
Result	`false`

`not_like_escape(string, like_specifier, escape_character)`

Description	Returns `false` if the `string` matches the `like_specifier` (see Pattern Matching) using case-sensitive matching. `escape_character` is used to search for wildcard characters in the `string`.
Example	`not_like_escape('a%c', 'a$%c', '$')`
Result	`false`

`parse_dirname(path[, separator])`

Description	Returns the top-level directory name from the given `path`. `separator` options: `system`, `both_slash` (default), `forward_slash`, `backslash`.
Example	`parse_dirname('path/to/file.csv', 'system')`
Result	`path`

`parse_dirpath(path[, separator])`

Description	Returns the head of the `path` (the pathname until the last slash) similarly to Python's `os.path.dirname`. `separator` options: `system`, `both_slash` (default), `forward_slash`, `backslash`.
Example	`parse_dirpath('path/to/file.csv', 'forward_slash')`

Result	`path/to`

`parse_filename(string[, trim_extension][, separator])`

Description	Returns the last component of the `path` similarly to Python's `os.path.basename` function. If `trim_extension` is `true`, the file extension will be removed (defaults to `false`). `separator` options: `system`, `both_slash` (default), `forward_slash`, `backslash`.
Example	`parse_filename('path/to/file.csv', true, 'forward_slash')`
Result	`file`

`parse_path(path[, separator])`

Description	Returns a list of the components (directories and filename) in the `path` similarly to Python's `pathlib.parts` function. `separator` options: `system`, `both_slash` (default), `forward_slash`, `backslash`.
Example	`parse_path('path/to/file.csv', 'system')`
Result	`[path, to, file.csv]`

`position(search_string IN string)`

Description	Return location of first occurrence of `search_string` in `string`, counting from 1. Returns 0 if no match found.
Example	`position('b' IN 'abc')`
Result	2
Aliases	`instr`, `strpos`

`prefix(string, search_string)`

Description	Returns `true` if `string` starts with `search_string`.
Example	`prefix('abc', 'ab')`
Result	`true`

`printf(format, ...)`

Description	Formats a `string` using printf syntax.
Example	`printf('Benchmark "%s" took %d seconds', 'CSV', 42)`
Result	`Benchmark "CSV" took 42 seconds`

`read_text(source)`

Description	Returns the content from `source` (a filename, a list of filenames, or a glob pattern) as a VARCHAR. The file content is first validated to be valid UTF-8. If `read_text` attempts to read a file with invalid UTF-8 an error is thrown suggesting to use `read_blob` instead. See the `read_text` guide for more details.
Example	`read_text('hello.txt')`
Result	`hello\n`

`regexp_escape(string)`

Description	Escapes special patterns to turn `string` into a regular expression similarly to Python's `re.escape` function.
Example	`regexp_escape('https://duckdb.org')`
Result	`https\:\/\/duckdb\.org`

`regexp_extract(string, regex[, group][, options])`

Description	If `string` contains the `regex` pattern, returns the capturing group specified by optional parameter `group`; otherwise, returns the empty string. The `group` must be a constant value. If no `group` is given, it defaults to 0. A set of optional regex `options` can be set.
Example	`regexp_extract('ABC', '([a-z])(b)', 1, 'i')`
Result	A

`regexp_extract(string, regex, name_list[, options])`

Description	If `string` contains the `regex` pattern, returns the capturing groups as a struct with corresponding names from `name_list`; otherwise, returns a struct with the same keys and empty strings as values. A set of optional regex `options` can be set.
Example	`regexp_extract('John Doe', '([a-z]+) ([a-z]+)', ['first_name', 'last_name'], 'i')`
Result	`{'first_name': John, 'last_name': Doe}`

`regexp_extract_all(string, regex[, group][, options])`

Description	Finds non-overlapping occurrences of the `regex` in the `string` and returns the corresponding values of the capturing `group`. A set of optional regex `options` can be set.
Example	`regexp_extract_all('Peter: 33, Paul:14', '(\w+):\s*(\d+)', 2)`
Result	`[33, 14]`

`regexp_extract_all(string, regex, name_list[, options])`

Description	Finds non-overlapping occurrences of `regex` in `string` and returns the capturing groups as a list of structs with corresponding names from `name_list`. A set of optional regex `options` can be set.

Example	`regexp_extract_all('Peter: 33, Paul: 14', '(\w+):\s*(\d+)', ['name', 'age'])`
Result	`[{'name': Peter, 'age': 33}, {'name': Paul, 'age': 14}]`

`regexp_full_match(string, regex[, col2])`

Description	Returns `true` if the entire `string` matches the `regex`. A set of optional regex `options` can be set.
Example	`regexp_full_match('anabanana', '(an)*')`
Result	`false`

`regexp_matches(string, regex[, options])`

Description	Returns `true` if `string` contains the `regex`, `false` otherwise. A set of optional regex `options` can be set.
Example	`regexp_matches('anabanana', '(an)*')`
Result	`true`

`regexp_replace(string, regex, replacement[, options])`

Description	If `string` contains the `regex`, replaces the matching part with `replacement`. A set of optional regex `options` can be set.
Example	`regexp_replace('hello', '[lo]', '-')`
Result	`he-lo`

`regexp_split_to_table(string, regex)`

Description	Splits the `string` along the `regex` and returns a row for each part.
Example	`regexp_split_to_table('hello world; 42', ';? ')`
Result	Multiple rows: `'hello'`, `'world'`, `'42'`

`repeat(string, count)`

Description	Repeats the `string` `count` number of times.
Example	`repeat('A', 5)`
Result	AAAAA

`replace(string, source, target)`

Description	Replaces any occurrences of the `source` with `target` in `string`.
Example	`replace('hello', 'l', '-')`

Result	`he--o`

`reverse(string)`

Description	Reverses the `string`.
Example	`reverse('hello')`
Result	`olleh`

`right(string, count)`

Description	Extract the right-most `count` characters.
Example	`right('Hello🦆', 3)`
Result	`lo🦆`

`right_grapheme(string, count)`

Description	Extracts the right-most `count` grapheme clusters.
Example	`right_grapheme('👩🏻‍♂️👩🏽‍♀️', 1)`
Result	👩🏽‍♀️

`rpad(string, count, character)`

Description	Pads the `string` with the `character` on the right until it has `count` characters. Truncates the `string` on the right if it has more than `count` characters.
Example	`rpad('hello', 10, '<')`
Result	`hello<<<<<`

`rtrim(string[, characters])`

Description	Removes any occurrences of any of the `characters` from the right side of the `string`. `characters` defaults to `space`.
Example 1	rtrim(' test ')
Result	test
Example 2	`rtrim('>>>>test<<', '><')`
Result	`>>>>test`

`sha1(value)`

Description	Returns a VARCHAR with the SHA-1 hash of the `value`.
Example	`sha1('🦆')`

Result	`949bf843dc338be348fb9525d1eb535d31241d76`

`sha256(value)`

Description	Returns a VARCHAR with the SHA-256 hash of the `value`
Example	`sha256('🦆')`
Result	`d7a5c5e0d1d94c32218539e7e47d4ba9c3c7b77d61332fb60d633dde89e473fb`

`split_part(string, separator, index)`

Description	Splits the `string` along the `separator` and returns the data at the (1-based) `index` of the list. If the `index` is outside the bounds of the list, return an empty string (to match PostgreSQL's behavior).
Example	`split_part('a;b;c', ';', 2)`
Result	b

`starts_with(string, search_string)`

Description	Returns `true` if `string` begins with `search_string`.
Example	`starts_with('abc', 'a')`
Result	`true`
Alias	`^@`

`string_split(string, separator)`

Description	Splits the `string` along the `separator`.
Example	`string_split('hello-world', '-')`
Result	`[hello, world]`
Aliases	`split`, `str_split`, `string_to_array`

`string_split_regex(string, regex[, options])`

Description	Splits the `string` along the `regex`. A set of optional regex `options` can be set.
Example	`string_split_regex('hello world; 42', ';? ')`
Result	`[hello, world, 42]`
Aliases	`regexp_split_to_array`, `str_split_regex`

`strip_accents(string)`

Description	Strips accents from `string`.

Example	`strip_accents('mühleisen')`
Result	`muhleisen`

`strlen(string)`

Description	Number of bytes in `string`.
Example	`strlen('🦆')`
Result	4

`substring(string, start[, length])`

Description	Extracts substring starting from character `start` up to the end of the string. If optional argument `length` is set, extracts a substring of `length` characters instead. Note that a `start` value of `1` refers to the first character of the `string`.
Example 1	`substring('Hello', 2)`
Result	`ello`
Example 2	`substring('Hello', 2, 2)`
Result	`el`
Alias	`substr`

`substring_grapheme(string, start[, length])`

Description	Extracts substring starting from grapheme clusters `start` up to the end of the string. If optional argument `length` is set, extracts a substring of `length` grapheme clusters instead. Note that a `start` value of `1` refers to the `first` character of the `string`.
Example 1	`substring_grapheme('🦆🤦🏼‍♂️🤦🏾‍♀️🦆', 3)`
Result	🤦🏾‍♀️🦆
Example 2	`substring_grapheme('🦆🤦🏼‍♂️🤦🏾‍♀️🦆', 3, 2)`
Result	🤦🏾‍♀️🦆

`suffix(string, search_string)`

Description	Returns `true` if `string` ends with `search_string`. Note that collations are not supported.
Example	`suffix('abc', 'bc')`
Result	`true`
Alias	`ends_with`

`to_base(number, radix[, min_length])`

Description	Converts `number` to a string in the given base `radix`, optionally padding with leading zeros to `min_length`.
Example	`to_base(42, 16, 5)`
Result	`0002A`

`to_base64(blob)`

Description	Converts a `blob` to a base64 encoded string.
Example	`to_base64('A'::BLOB)`
Result	`QQ==`
Alias	`base64`

`translate(string, from, to)`

Description	Replaces each character in `string` that matches a character in the `from` set with the corresponding character in the `to` set. If `from` is longer than `to`, occurrences of the extra characters in `from` are deleted.
Example	`translate('12345', '143', 'ax')`
Result	`a2x5`

`trim(string[, characters])`

Description	Removes any occurrences of any of the `characters` from either side of the `string`. `characters` defaults to `space`.
Example 1	trim(' test ')
Result	`test`
Example 2	`trim('>>>>test<<', '><')`
Result	`test`

`unbin(value)`

Description	Converts a `value` from binary representation to a blob.
Example	`unbin('0110')`
Result	`\x06`
Alias	`from_binary`

`unhex(value)`

Description	Converts a `value` from hexadecimal representation to a blob.
Example	`unhex('2A')`

Result	*
Alias	from_hex

unicode(string)

Description	Returns an INTEGER representing the unicode codepoint of the first character in the string.
Example	[unicode('âbcd'), unicode('â'), unicode(''), unicode(NULL)]
Result	[226, 226, -1, NULL]
Alias	ord

upper(string)

Description	Converts string to upper case.
Example	upper('Hello')
Result	HELLO
Alias	ucase

url_decode(string)

Description	Decodes a URL from a representation using Percent-Encoding.
Example	url_decode('https%3A%2F%2Fduckdb.org%2Fwhy_duckdb%23portable')
Result	https://duckdb.org/why_duckdb#portable

url_encode(string)

Description	Encodes a URL to a representation using Percent-Encoding.
Example	url_encode('this string has/ special+ characters>')
Result	this%20string%20has%2F%20special%2B%20characters%3E

Text Similarity Functions

These functions are used to measure the similarity of two strings using various similarity measures.

Function	Description
damerau_levenshtein(s1, s2)	Extension of Levenshtein distance to also include transposition of adjacent characters as an allowed edit operation. In other words, the minimum number of edit operations (insertions, deletions, substitutions or transpositions) required to change one string to another. Characters of different cases (e.g., a and A) are considered different.
editdist3(s1, s2)	Alias for levenshtein.

Function	Description
`hamming(s1, s2)`	The Hamming distance between two strings, i.e., the number of positions with different characters for two strings of equal length. Strings must be of equal length. Characters of different cases (e.g., a and A) are considered different.
`jaccard(s1, s2)`	The Jaccard similarity between two strings. Characters of different cases (e.g., a and A) are considered different. Returns a number between 0 and 1.
`jaro_similarity(s1, s2[, score_cutoff])`	The Jaro similarity between two strings. Characters of different cases (e.g., a and A) are considered different. Returns a number between 0 and 1. For similarity < `score_cutoff`, 0 is returned instead. `score_cutoff` defaults to 0.
`jaro_winkler_similarity(s1, s2[, score_cutoff])`	The Jaro-Winkler similarity between two strings. Characters of different cases (e.g., a and A) are considered different. Returns a number between 0 and 1. For similarity < `score_cutoff`, 0 is returned instead. `score_cutoff` defaults to 0.
`levenshtein(s1, s2)`	The minimum number of single-character edits (insertions, deletions or substitutions) required to change one string to the other. Characters of different cases (e.g., a and A) are considered different.
`mismatches(s1, s2)`	Alias for `hamming`.

`damerau_levenshtein(s1, s2)`

Description	Extension of Levenshtein distance to also include transposition of adjacent characters as an allowed edit operation. In other words, the minimum number of edit operations (insertions, deletions, substitutions or transpositions) required to change one string to another. Characters of different cases (e.g., a and A) are considered different.
Example	`damerau_levenshtein('duckdb', 'udckbd')`
Result	`2`

`hamming(s1, s2)`

Description	The Hamming distance between two strings, i.e., the number of positions with different characters for two strings of equal length. Strings must be of equal length. Characters of different cases (e.g., a and A) are considered different.
Example	`hamming('duck', 'luck')`
Result	`1`
Alias	`mismatches`

`jaccard(s1, s2)`

Description	The Jaccard similarity between two strings. Characters of different cases (e.g., a and A) are considered different. Returns a number between 0 and 1.
Example	`jaccard('duck', 'luck')`
Result	`0.6`

`jaro_similarity(s1, s2[, score_cutoff])`

Description	The Jaro similarity between two strings. Characters of different cases (e.g., a and A) are considered different. Returns a number between 0 and 1. For similarity < `score_cutoff`, 0 is returned instead. `score_cutoff` defaults to 0.
Example	`jaro_similarity('duck', 'duckdb')`
Result	`0.8888888888888888`

`jaro_winkler_similarity(s1, s2[, score_cutoff])`

Description	The Jaro-Winkler similarity between two strings. Characters of different cases (e.g., a and A) are considered different. Returns a number between 0 and 1. For similarity < `score_cutoff`, 0 is returned instead. `score_cutoff` defaults to 0.
Example	`jaro_winkler_similarity('duck', 'duckdb')`
Result	`0.9333333333333333`

`levenshtein(s1, s2)`

Description	The minimum number of single-character edits (insertions, deletions or substitutions) required to change one string to the other. Characters of different cases (e.g., a and A) are considered different.
Example	`levenshtein('duck', 'db')`
Result	3
Alias	`editdist3`

Formatters

`fmt` Syntax

The `format(format, parameters...)` function formats strings, loosely following the syntax of the {fmt} open-source formatting library.

Format without additional parameters:

```
SELECT format('Hello world'); -- Hello world
```

Format a string using {}:

```
SELECT format('The answer is {}', 42); -- The answer is 42
```

Format a string using positional arguments:

```
SELECT format('I''d rather be {1} than {0}.', 'right', 'happy'); -- I'd rather be happy than right.
```

Format Specifiers

Specifier	Description	Example
`{:d}`	integer	`654321`
`{:E}`	scientific notation	`3.141593E+00`

Specifier	Description	Example
`{:f}`	float	`4.560000`
`{:o}`	octal	`2375761`
`{:s}`	string	`asd`
`{:x}`	hexadecimal	`9fbf1`
`{:tX}`	integer, X is the thousand separator	`654 321`

Formatting Types Integers:

```
SELECT format('{} + {} = {}', 3, 5, 3 + 5); -- 3 + 5 = 8
```

Booleans:

```
SELECT format('{} != {}', true, false); -- true != false
```

Format datetime values:

```
SELECT format('{}', DATE '1992-01-01'); -- 1992-01-01
SELECT format('{}', TIME '12:01:00'); -- 12:01:00
SELECT format('{}', TIMESTAMP '1992-01-01 12:01:00'); -- 1992-01-01 12:01:00
```

Format BLOB:

```
SELECT format('{}', BLOB '\x00hello'); -- \x00hello
```

Pad integers with 0s:

```
SELECT format('{:04d}', 33); -- 0033
```

> Padding cannot currently be combined with the specification of a thousands separator.

Create timestamps from integers:

```
SELECT format('{:02d}:{:02d}:{:02d} {}', 12, 3, 16, 'AM'); -- 12:03:16 AM
```

Convert to hexadecimal:

```
SELECT format('{:x}', 123_456_789); -- 75bcd15
```

Convert to binary:

```
SELECT format('{:b}', 123_456_789); -- 111010110111100110100010101
```

Print Numbers with Thousand Separators Integers:

```
SELECT format('{:,}',  123_456_789); -- 123,456,789
SELECT format('{:t.}', 123_456_789); -- 123.456.789
SELECT format('{:''}', 123_456_789); -- 123'456'789
SELECT format('{:_}',  123_456_789); -- 123_456_789
SELECT format('{:t }', 123_456_789); -- 123 456 789
SELECT format('{:tX}', 123_456_789); -- 123X456X789
```

Float, double and decimal:

```
SELECT format('{:,f}',    123456.789); -- 123,456.78900
SELECT format('{:,.2f}',  123456.789); -- 123,456.79
SELECT format('{:t..2f}', 123456.789); -- 123.456,79
```

`printf` Syntax

The `printf(format, parameters...)` function formats strings using the `printf` syntax.

Format without additional parameters:

```
SELECT printf('Hello world');
```

```
Hello world
```

Format a string using arguments in a given order:

```
SELECT printf('The answer to %s is %d', 'life', 42);
```

```
The answer to life is 42
```

Format a string using positional arguments `%position$formatter`, e.g., the second parameter as a string is encoded as `%2$s`:

```
SELECT printf('I''d rather be %2$s than %1$s.', 'right', 'happy');
```

```
I'd rather be happy than right.
```

Format Specifiers

Specifier	Description	Example
%c	character code to character	a
%d	integer	654321
%Xd	integer with thousand separator X from `,`, `.`, `''`, `_`	654_321
%E	scientific notation	3.141593E+00
%f	float	4.560000
%hd	integer	654321
%hhd	integer	654321
%lld	integer	654321
%o	octal	2375761
%s	string	asd
%x	hexadecimal	9fbf1

Formatting Types Integers:

```
SELECT printf('%d + %d = %d', 3, 5, 3 + 5); -- 3 + 5 = 8
```

Booleans:

```
SELECT printf('%s != %s', true, false); -- true != false
```

Format datetime values:

```
SELECT printf('%s', DATE '1992-01-01'); -- 1992-01-01
SELECT printf('%s', TIME '12:01:00'); -- 12:01:00
SELECT printf('%s', TIMESTAMP '1992-01-01 12:01:00'); -- 1992-01-01 12:01:00
```

Format BLOB:

```
SELECT printf('%s', BLOB '\x00hello'); -- \x00hello
```

Pad integers with 0s:

```
SELECT printf('%04d', 33); -- 0033
```

Create timestamps from integers:

```
SELECT printf('%02d:%02d:%02d %s', 12, 3, 16, 'AM'); -- 12:03:16 AM
```

Convert to hexadecimal:

```
SELECT printf('%x', 123_456_789); -- 75bcd15
```

Convert to binary:

```
SELECT printf('%b', 123_456_789); -- 111010110111100110100010101
```

Thousand Separators Integers:

```
SELECT printf('%,d',  123_456_789); -- 123,456,789
SELECT printf('%.d',  123_456_789); -- 123.456.789
SELECT printf('%''d', 123_456_789); -- 123'456'789
SELECT printf('%_d',  123_456_789); -- 123_456_789
```

Float, double and decimal:

```
SELECT printf('%,f',   123456.789); -- 123,456.789000
SELECT printf('%,.2f', 123456.789); -- 123,456.79
```

Time Functions

This section describes functions and operators for examining and manipulating `TIME` values.

Time Operators

The table below shows the available mathematical operators for `TIME` types.

Operator	Description	Example	Result
`+`	addition of an `INTERVAL`	`TIME '01:02:03' + INTERVAL 5 HOUR`	`06:02:03`
`-`	subtraction of an `INTERVAL`	`TIME '06:02:03' - INTERVAL 5 HOUR`	`01:02:03`

Time Functions

The table below shows the available scalar functions for `TIME` types.

Name	Description
`date_diff(part, starttime, endtime)`	The number of `part` boundaries between `starttime` and `endtime`, inclusive of the larger time and exclusive of the smaller time.
`date_part(part, time)`	Get subfield (equivalent to `extract`).
`date_sub(part, starttime, endtime)`	The signed length of the interval between `starttime` and `endtime`, truncated to whole multiples of `part`.
`extract(part FROM time)`	Get subfield from a time.

Name	Description
`get_current_time()`	Current time (start of current transaction).
`make_time(bigint, bigint, double)`	The time for the given parts.

The only date parts that are defined for times are `epoch`, `hours`, `minutes`, `seconds`, `milliseconds` and `microseconds`.

`date_diff(part, starttime, endtime)`

Description	The number of `part` boundaries between `starttime` and `endtime`, inclusive of the larger time and exclusive of the smaller time.
Example	`date_diff('hour', TIME '01:02:03', TIME '06:01:03')`
Result	5
Alias	`datediff`

`date_part(part, time)`

Description	Get subfield (equivalent to `extract`).
Example	`date_part('minute', TIME '14:21:13')`
Result	21
Alias	`datepart`

`date_sub(part, starttime, endtime)`

Description	The signed length of the interval between `starttime` and `endtime`, truncated to whole multiples of `part`.
Example	`date_sub('hour', TIME '01:02:03', TIME '06:01:03')`
Result	4
Alias	`datesub`

`extract(part FROM time)`

Description	Get subfield from a time.
Example	`extract('hour' FROM TIME '14:21:13')`
Result	14

`get_current_time()`

Description	Current time (start of current transaction) in the local time zone as `TIMETZ`.
Example	`get_current_time()`

Result	`06:09:59.988+2`
Alias	`current_time` (no parentheses necessary)

`make_time(bigint, bigint, double)`

Description	The time for the given parts.
Example	`make_time(13, 34, 27.123456)`
Result	`13:34:27.123456`

Timestamp Functions

This section describes functions and operators for examining and manipulating `TIMESTAMP` values. See also the related `TIMESTAMPTZ` functions.

Timestamp Operators

The table below shows the available mathematical operators for `TIMESTAMP` types.

Operator	Description	Example	Result
`+`	addition of an `INTERVAL`	`TIMESTAMP '1992-03-22 01:02:03' + INTERVAL 5 DAY`	`1992-03-27 01:02:03`
`-`	subtraction of `TIMESTAMP`s	`TIMESTAMP '1992-03-27' - TIMESTAMP '1992-03-22'`	`5 days`
`-`	subtraction of an `INTERVAL`	`TIMESTAMP '1992-03-27 01:02:03' - INTERVAL 5 DAY`	`1992-03-22 01:02:03`

Adding to or subtracting from infinite values produces the same infinite value.

Scalar Timestamp Functions

The table below shows the available scalar functions for `TIMESTAMP` values.

Name	Description
`age(timestamp, timestamp)`	Subtract arguments, resulting in the time difference between the two timestamps.
`age(timestamp)`	Subtract from current_date.
`ago(interval)`	Subtracts an interval from the current timestamp.
`century(timestamp)`	Extracts the century of a timestamp.
`current_localtimestamp()`	Returns the current timestamp (at the start of the transaction).
`date_diff(part, starttimestamp, endtimestamp)`	The number of `part` boundaries between `starttimestamp` and `endtimestamp`, inclusive of the larger timestamp and exclusive of the smaller timestamp.

Name	Description
`date_part([part, ...], timestamp)`	Get the listed subfields as a `struct`. The list must be constant.
`date_part(part, timestamp)`	Get subfield (equivalent to `extract`).
`date_sub(part, starttimestamp, endtimestamp)`	The signed length of the interval between `starttimestamp` and `endtimestamp`, truncated to whole multiples of `part`.
`date_trunc(part, timestamp)`	Truncate to specified precision.
`dayname(timestamp)`	The (English) name of the weekday.
`epoch_ms(timestamp)`	Returns the total number of milliseconds since the epoch.
`epoch_ns(timestamp)`	Returns the total number of nanoseconds since the epoch.
`epoch_us(timestamp)`	Returns the total number of microseconds since the epoch.
`epoch(timestamp)`	Returns the total number of seconds since the epoch.
`extract(field FROM timestamp)`	Get subfield from a timestamp.
`greatest(timestamp, timestamp)`	The later of two timestamps.
`isfinite(timestamp)`	Returns true if the timestamp is finite, false otherwise.
`isinf(timestamp)`	Returns true if the timestamp is infinite, false otherwise.
`julian(timestamp)`	Extract the Julian Day number from a timestamp.
`last_day(timestamp)`	The last day of the month.
`least(timestamp, timestamp)`	The earlier of two timestamps.
`make_timestamp(bigint, bigint, bigint, bigint, bigint, double)`	The timestamp for the given parts.
`make_timestamp(microseconds)`	Converts microseconds since the epoch to a timestamp.
`make_timestamp_ms(milliseconds)`	Converts milliseconds since the epoch to a timestamp.
`make_timestamp_ns(nanoseconds)`	Converts nanoseconds since the epoch to a timestamp.
`monthname(timestamp)`	The (English) name of the month.
`strftime(timestamp, format)`	Converts timestamp to string according to the format string.
`strptime(text, format-list)`	Converts the string `text` to timestamp applying the format strings in the list until one succeeds. Throws an error on failure. To return `NULL` on failure, use `try_strptime`.
`strptime(text, format)`	Converts the string `text` to timestamp according to the format string. Throws an error on failure. To return `NULL` on failure, use `try_strptime`.
`time_bucket(bucket_width, timestamp[, offset])`	Truncate `timestamp` to a grid of width `bucket_width`. The grid is anchored at `2000-01-01 00:00:00[ + offset]` when `bucket_width` is a number of months or coarser units, else `2000-01-03 00:00:00[ + offset]`. Note that `2000-01-03` is a Monday.

Name	Description
`time_bucket(bucket_width, timestamp[, origin])`	Truncate `timestamp` to a grid of width `bucket_width`. The grid is anchored at the `origin` timestamp, which defaults to `2000-01-01 00:00:00` when `bucket_width` is a number of months or coarser units, else `2000-01-03 00:00:00`. Note that `2000-01-03` is a Monday.
`try_strptime(text, format-list)`	Converts the string `text` to timestamp applying the format strings in the list until one succeeds. Returns `NULL` on failure.
`try_strptime(text, format)`	Converts the string `text` to timestamp according to the format string. Returns `NULL` on failure.

There are also dedicated extraction functions to get the subfields.

Functions applied to infinite dates will either return the same infinite dates (e.g., `greatest`) or `NULL` (e.g., `date_part`) depending on what "makes sense". In general, if the function needs to examine the parts of the infinite date, the result will be `NULL`.

`age(timestamp, timestamp)`

Description	Subtract arguments, resulting in the time difference between the two timestamps.
Example	`age(TIMESTAMP '2001-04-10', TIMESTAMP '1992-09-20')`
Result	`8 years 6 months 20 days`

`age(timestamp)`

Description	Subtract from current_date.
Example	`age(TIMESTAMP '1992-09-20')`
Result	`29 years 1 month 27 days 12:39:00.844`

`ago(interval)`

Description	Subtracts an interval from the current timestamp, returning a timestamp in the past. Equivalent to `current_timestamp - interval`.
Example	`ago(INTERVAL 1 HOUR)`
Result	`2024-11-30 12:28:48.895` (if current time is `2024-11-30 13:28:48.895`)

`century(timestamp)`

Description	Extracts the century of a timestamp.
Example	`century(TIMESTAMP '1992-03-22')`
Result	`20`

`current_localtimestamp()`

Description	Returns the current timestamp with time zone (at the start of the transaction).
Example	`current_localtimestamp()`
Result	`2024-11-30 13:28:48.895`

`date_diff(part, starttimestamp, endtimestamp)`

Description	The signed number of `part` boundaries between `starttimestamp` and `endtimestamp`, inclusive of the larger timestamp and exclusive of the smaller timestamp.
Example	`date_diff('hour', TIMESTAMP '1992-09-30 23:59:59', TIMESTAMP '1992-10-01 01:58:00')`
Result	`2`

`date_part([part, ...], timestamp)`

Description	Get the listed subfields as a `struct`. The list must be constant.
Example	`date_part(['year', 'month', 'day'], TIMESTAMP '1992-09-20 20:38:40')`
Result	`{year: 1992, month: 9, day: 20}`

`date_part(part, timestamp)`

Description	Get subfield (equivalent to `extract`).
Example	`date_part('minute', TIMESTAMP '1992-09-20 20:38:40')`
Result	`38`

`date_sub(part, starttimestamp, endtimestamp)`

Description	The signed length of the interval between `starttimestamp` and `endtimestamp`, truncated to whole multiples of `part`.
Example	`date_sub('hour', TIMESTAMP '1992-09-30 23:59:59', TIMESTAMP '1992-10-01 01:58:00')`
Result	`1`

`date_trunc(part, timestamp)`

Description	Truncate to specified precision.
Example	`date_trunc('hour', TIMESTAMP '1992-09-20 20:38:40')`
Result	`1992-09-20 20:00:00`

`dayname(timestamp)`

Description	The (English) name of the weekday.
Example	`dayname(TIMESTAMP '1992-03-22')`
Result	Sunday

`epoch_ms(timestamp)`

Description	Returns the total number of milliseconds since the epoch.
Example	`epoch_ms(TIMESTAMP '2021-08-03 11:59:44.123456')`
Result	`1627991984123`

`epoch_ns(timestamp)`

Description	Returns the total number of nanoseconds since the epoch.
Example	`epoch_ns(TIMESTAMP '2021-08-03 11:59:44.123456')`
Result	`1627991984123456000`

`epoch_us(timestamp)`

Description	Returns the total number of microseconds since the epoch.
Example	`epoch_us(TIMESTAMP '2021-08-03 11:59:44.123456')`
Result	`1627991984123456`

`epoch(timestamp)`

Description	Returns the total number of seconds since the epoch.
Example	`epoch('2022-11-07 08:43:04'::TIMESTAMP);`
Result	`1667810584`

`extract(field FROM timestamp)`

Description	Get subfield from a timestamp.
Example	`extract('hour' FROM TIMESTAMP '1992-09-20 20:38:48')`
Result	`20`

`greatest(timestamp, timestamp)`

Description	The later of two timestamps.

Example	`greatest(TIMESTAMP '1992-09-20 20:38:48', TIMESTAMP '1992-03-22 01:02:03.1234')`
Result	`1992-09-20 20:38:48`

`isfinite(timestamp)`

Description	Returns true if the timestamp is finite, false otherwise.
Example	`isfinite(TIMESTAMP '1992-03-07')`
Result	`true`

`isinf(timestamp)`

Description	Returns true if the timestamp is infinite, false otherwise.
Example	`isinf(TIMESTAMP '-infinity')`
Result	`true`

`julian(timestamp)`

Description	Extract the Julian Day number from a timestamp.
Example	`julian(TIMESTAMP '1992-03-22 01:02:03.1234')`
Result	`2448704.043091706`

`last_day(timestamp)`

Description	The last day of the month.
Example	`last_day(TIMESTAMP '1992-03-22 01:02:03.1234')`
Result	`1992-03-31`

`least(timestamp, timestamp)`

Description	The earlier of two timestamps.
Example	`least(TIMESTAMP '1992-09-20 20:38:48', TIMESTAMP '1992-03-22 01:02:03.1234')`
Result	`1992-03-22 01:02:03.1234`

`make_timestamp(bigint, bigint, bigint, bigint, bigint, double)`

Description	The timestamp for the given parts.
Example	`make_timestamp(1992, 9, 20, 13, 34, 27.123456)`
Result	`1992-09-20 13:34:27.123456`

`make_timestamp(microseconds)`

Description	Converts microseconds since the epoch to a timestamp.
Example	`make_timestamp(1667810584123456)`
Result	`2022-11-07 08:43:04.123456`

`make_timestamp_ms(milliseconds)`

Description	Converts milliseconds since the epoch to a timestamp.
Example	`make_timestamp_ms(1667810584123)`
Result	`2022-11-07 08:43:04.123`

`make_timestamp_ns(nanoseconds)`

Description	Converts nanoseconds since the epoch to a timestamp.
Example	`make_timestamp_ns(1667810584123456789)`
Result	`2022-11-07 08:43:04.123456789`

`monthname(timestamp)`

Description	The (English) name of the month.
Example	`monthname(TIMESTAMP '1992-09-20')`
Result	`September`

`strftime(timestamp, format)`

Description	Converts timestamp to string according to the format string.
Example	`strftime(timestamp '1992-01-01 20:38:40', '%a, %-d %B %Y - %I:%M:%S %p')`
Result	`Wed, 1 January 1992 - 08:38:40 PM`

`strptime(text, format-list)`

Description	Converts the string `text` to timestamp applying the format strings in the list until one succeeds. Throws an error on failure. To return `NULL` on failure, use `try_strptime`.
Example	`strptime('4/15/2023 10:56:00', ['%d/%m/%Y %H:%M:%S', '%m/%d/%Y %H:%M:%S'])`
Result	`2023-04-15 10:56:00`

`strptime(text, format)`

Description	Converts the string `text` to timestamp according to the format string. Throws an error on failure. To return `NULL` on failure, use `try_strptime`.
Example	`strptime('Wed, 1 January 1992 - 08:38:40 PM', '%a, %-d %B %Y - %I:%M:%S %p')`
Result	`1992-01-01 20:38:40`

`time_bucket(bucket_width, timestamp[, offset])`

Description	Truncate `timestamp` to a grid of width `bucket_width`. The grid includes `2000-01-01 00:00:00[ + offset]` when `bucket_width` is a number of months or coarser units, else `2000-01-03 00:00:00[ + offset]`. Note that `2000-01-03` is a Monday.
Example	`time_bucket(INTERVAL '10 minutes', TIMESTAMP '1992-04-20 15:26:00-07', INTERVAL '5 minutes')`
Result	`1992-04-20 15:25:00`

`time_bucket(bucket_width, timestamp[, origin])`

Description	Truncate `timestamp` to a grid of width `bucket_width`. The grid includes the `origin` timestamp, which defaults to `2000-01-01 00:00:00` when `bucket_width` is a number of months or coarser units, else `2000-01-03 00:00:00`. Note that `2000-01-03` is a Monday.
Example	`time_bucket(INTERVAL '2 weeks', TIMESTAMP '1992-04-20 15:26:00', TIMESTAMP '1992-04-01 00:00:00')`
Result	`1992-04-15 00:00:00`

`try_strptime(text, format-list)`

Description	Converts the string `text` to timestamp applying the format strings in the list until one succeeds. Returns `NULL` on failure.
Example	`try_strptime('4/15/2023 10:56:00', ['%d/%m/%Y %H:%M:%S', '%m/%d/%Y %H:%M:%S'])`
Result	`2023-04-15 10:56:00`

`try_strptime(text, format)`

Description	Converts the string `text` to timestamp according to the format string. Returns `NULL` on failure.
Example	`try_strptime('Wed, 1 January 1992 - 08:38:40 PM', '%a, %-d %B %Y - %I:%M:%S %p')`
Result	`1992-01-01 20:38:40`

Timestamp Table Functions

The table below shows the available table functions for `TIMESTAMP` types.

Name	Description
`generate_series(timestamp, timestamp, interval)`	Generate a table of timestamps in the closed range, stepping by the interval.
`range(timestamp, timestamp, interval)`	Generate a table of timestamps in the half open range, stepping by the interval.

> Infinite values are not allowed as table function bounds.

`generate_series(timestamp, timestamp, interval)`

Description	Generate a table of timestamps in the closed range, stepping by the interval.
Example	`generate_series(TIMESTAMP '2001-04-10', TIMESTAMP '2001-04-11', INTERVAL 30 MINUTE)`

`range(timestamp, timestamp, interval)`

Description	Generate a table of timestamps in the half open range, stepping by the interval.
Example	`range(TIMESTAMP '2001-04-10', TIMESTAMP '2001-04-11', INTERVAL 30 MINUTE)`

Timestamp with Time Zone Functions

This section describes functions and operators for examining and manipulating `TIMESTAMP WITH TIME ZONE` (or `TIMESTAMPTZ`) values. See also the related `TIMESTAMP` functions.

Time zone support is provided by the built-in ICU extension.

In the examples below, the current time zone is presumed to be `America/Los_Angeles` using the Gregorian calendar.

Built-In Timestamp with Time Zone Functions

The table below shows the available scalar functions for `TIMESTAMPTZ` values. Since these functions do not involve binning or display, they are always available.

Name	Description
`current_timestamp`	Current date and time (start of current transaction).
`get_current_timestamp()`	Current date and time (start of current transaction).
`greatest(timestamptz, timestamptz)`	The later of two timestamps.
`isfinite(timestamptz)`	Returns true if the timestamp with time zone is finite, false otherwise.
`isinf(timestamptz)`	Returns true if the timestamp with time zone is infinite, false otherwise.
`least(timestamptz, timestamptz)`	The earlier of two timestamps.

Name	Description
`now()`	Current date and time (start of current transaction).
`timetz_byte_comparable(timetz)`	Converts a `TIME WITH TIME ZONE` to a `UBIGINT` sort key.
`to_timestamp(double)`	Converts seconds since the epoch to a timestamp with time zone.
`transaction_timestamp()`	Current date and time (start of current transaction).

`current_timestamp`

Description	Current date and time (start of current transaction).
Example	`current_timestamp`
Result	`2022-10-08 12:44:46.122-07`

`get_current_timestamp()`

Description	Current date and time (start of current transaction).
Example	`get_current_timestamp()`
Result	`2022-10-08 12:44:46.122-07`

`greatest(timestamptz, timestamptz)`

Description	The later of two timestamps.
Example	`greatest(TIMESTAMPTZ '1992-09-20 20:38:48', TIMESTAMPTZ '1992-03-22 01:02:03.1234')`
Result	`1992-09-20 20:38:48-07`

`isfinite(timestamptz)`

Description	Returns true if the timestamp with time zone is finite, false otherwise.
Example	`isfinite(TIMESTAMPTZ '1992-03-07')`
Result	`true`

`isinf(timestamptz)`

Description	Returns true if the timestamp with time zone is infinite, false otherwise.
Example	`isinf(TIMESTAMPTZ '-infinity')`
Result	`true`

`least(timestamptz, timestamptz)`

Description	The earlier of two timestamps.
Example	`least(TIMESTAMPTZ '1992-09-20 20:38:48', TIMESTAMPTZ '1992-03-22 01:02:03.1234')`
Result	`1992-03-22 01:02:03.1234-08`

`now()`

Description	Current date and time (start of current transaction).
Example	`now()`
Result	`2022-10-08 12:44:46.122-07`

`timetz_byte_comparable(timetz)`

Description	Converts a `TIME WITH TIME ZONE` to a `UBIGINT` sort key.
Example	`timetz_byte_comparable('18:18:16.21-07:00'::TIMETZ)`
Result	`2496691656335442799`

`to_timestamp(double)`

Description	Converts seconds since the epoch to a timestamp with time zone.
Example	`to_timestamp(1284352323.5)`
Result	`2010-09-13 04:32:03.5+00`

`transaction_timestamp()`

Description	Current date and time (start of current transaction).
Example	`transaction_timestamp()`
Result	`2022-10-08 12:44:46.122-07`

Timestamp with Time Zone Strings

With no time zone extension loaded, `TIMESTAMPTZ` values will be cast to and from strings using offset notation. This will let you specify an instant correctly without access to time zone information. For portability, `TIMESTAMPTZ` values will always be displayed using GMT offsets:

```
SELECT '2022-10-08 13:13:34-07'::TIMESTAMPTZ;
```

```
2022-10-08 20:13:34+00
```

If a time zone extension such as ICU is loaded, then a time zone can be parsed from a string and cast to a representation in the local time zone:

```
SELECT '2022-10-08 13:13:34 Europe/Amsterdam'::TIMESTAMPTZ::VARCHAR;
```

```
2022-10-08 04:13:34-07 -- the offset will differ based on your local time zone
```

ICU Timestamp with Time Zone Operators

The table below shows the available mathematical operators for `TIMESTAMP WITH TIME ZONE` values provided by the ICU extension.

Operator	Description	Example	Result
`+`	addition of an `INTERVAL`	`TIMESTAMPTZ '1992-03-22 01:02:03' + INTERVAL 5 DAY`	`1992-03-27 01:02:03`
`-`	subtraction of `TIMESTAMPTZ`s	`TIMESTAMPTZ '1992-03-27' - TIMESTAMPTZ '1992-03-22'`	`5 days`
`-`	subtraction of an `INTERVAL`	`TIMESTAMPTZ '1992-03-27 01:02:03' - INTERVAL 5 DAY`	`1992-03-22 01:02:03`

Adding to or subtracting from infinite values produces the same infinite value.

Addition and subtraction of intervals uses the ICU Calendar add function. For positive intervals (forwards in time) the fields are incremented from least to most significant. For negative intervals (backwards in time) the fields are decremented from most to least significant. This produces the same results as Postgres, but does not match some more recent calendar RFCs.

ICU Timestamp with Time Zone Functions

The table below shows the ICU provided scalar functions for `TIMESTAMP WITH TIME ZONE` values.

Name	Description
`age(timestamptz, timestamptz)`	Subtract arguments, resulting in the time difference between the two timestamps.
`age(timestamptz)`	Subtract from current_date.
`date_diff(part, starttimestamptz, endtimestamptz)`	The number of `part` boundaries between `starttimestamptz` and `endtimestamptz` inclusive of the larger timestamp and exclusive of the smaller timestamp.
`date_part([part, ...], timestamp)`	Get the listed subfields as a `struct`. The list must be constant.
`date_part(part, timestamp)`	Get subfield (equivalent to `extract`).
`date_sub(part, starttimestamptz, endtimestamptz)`	The signed length of the interval between `starttimestamptz` and `endtimestamptz`, truncated to whole multiples of `part`.
`date_trunc(part, timestamptz)`	Truncate to specified precision.
`epoch_ns(timestamptz)`	Converts a timestamptz to nanoseconds since the epoch.
`epoch_us(timestamptz)`	Converts a timestamptz to microseconds since the epoch.
`extract(field FROM timestamptz)`	Get subfield from a `TIMESTAMP WITH TIME ZONE`.
`last_day(timestamptz)`	The last day of the month.
`make_timestamptz(bigint, bigint, bigint, bigint, bigint, double, string)`	The `TIMESTAMP WITH TIME ZONE` for the given parts and time zone.

Name	Description
`make_timestamptz(bigint, bigint, bigint, bigint, bigint, double)`	The `TIMESTAMP WITH TIME ZONE` for the given parts in the current time zone.
`make_timestamptz(microseconds)`	The `TIMESTAMP WITH TIME ZONE` for the given µs since the epoch.
`strftime(timestamptz, format)`	Converts a `TIMESTAMP WITH TIME ZONE` value to string according to the format string.
`strptime(text, format)`	Converts string to `TIMESTAMP WITH TIME ZONE` according to the format string if `%Z` is specified.
`time_bucket(bucket_width, timestamptz[, offset])`	Truncate `timestamptz` to a grid of width `bucket_width`. The grid is anchored at `2000-01-01 00:00:00+00:00[ + offset]` when `bucket_width` is a number of months or coarser units, else `2000-01-03 00:00:00+00:00[ + offset]`. Note that `2000-01-03` is a Monday.
`time_bucket(bucket_width, timestamptz[, origin])`	Truncate `timestamptz` to a grid of width `bucket_width`. The grid is anchored at the `origin` timestamp, which defaults to `2000-01-01 00:00:00+00:00` when `bucket_width` is a number of months or coarser units, else `2000-01-03 00:00:00+00:00`. Note that `2000-01-03` is a Monday.
`time_bucket(bucket_width, timestamptz[, timezone])`	Truncate `timestamptz` to a grid of width `bucket_width`. The grid is anchored at the `origin` timestamp, which defaults to `2000-01-01 00:00:00` in the provided `timezone` when `bucket_width` is a number of months or coarser units, else `2000-01-03 00:00:00` in the provided `timezone`. The default timezone is `'UTC'`. Note that `2000-01-03` is a Monday.

`age(timestamptz, timestamptz)`

Description	Subtract arguments, resulting in the time difference between the two timestamps.
Example	`age(TIMESTAMPTZ '2001-04-10', TIMESTAMPTZ '1992-09-20')`
Result	`8 years 6 months 20 days`

`age(timestamptz)`

Description	Subtract from current_date.
Example	`age(TIMESTAMP '1992-09-20')`
Result	`29 years 1 month 27 days 12:39:00.844`

`date_diff(part, starttimestamptz, endtimestamptz)`

Description	The signed number of `part` boundaries between `starttimestamptz` and `endtimestamptz`, inclusive of the larger timestamp and exclusive of the smaller timestamp.
Example	`date_diff('hour', TIMESTAMPTZ '1992-09-30 23:59:59', TIMESTAMPTZ '1992-10-01 01:58:00')`
Result	2

`date_part([part, ...], timestamptz)`

Description	Get the listed subfields as a `struct`. The list must be constant.
Example	`date_part(['year', 'month', 'day'], TIMESTAMPTZ '1992-09-20 20:38:40-07')`
Result	`{year: 1992, month: 9, day: 20}`

`date_part(part, timestamptz)`

Description	Get subfield (equivalent to *extract*).
Example	`date_part('minute', TIMESTAMPTZ '1992-09-20 20:38:40')`
Result	`38`

`date_sub(part, starttimestamptz, endtimestamptz)`

Description	The signed length of the interval between `starttimestamptz` and `endtimestamptz`, truncated to whole multiples of `part`.
Example	`date_sub('hour', TIMESTAMPTZ '1992-09-30 23:59:59', TIMESTAMPTZ '1992-10-01 01:58:00')`
Result	`1`

`date_trunc(part, timestamptz)`

Description	Truncate to specified precision.
Example	`date_trunc('hour', TIMESTAMPTZ '1992-09-20 20:38:40')`
Result	`1992-09-20 20:00:00`

`epoch_ns(timestamptz)`

Description	Converts a timestamptz to nanoseconds since the epoch.
Example	`epoch_ns('2022-11-07 08:43:04.123456+00'::TIMESTAMPTZ);`
Result	`1667810584123456000`

`epoch_us(timestamptz)`

Description	Converts a timestamptz to microseconds since the epoch.
Example	`epoch_us('2022-11-07 08:43:04.123456+00'::TIMESTAMPTZ);`
Result	`1667810584123456`

`extract(field FROM timestamptz)`

Description	Get subfield from a `TIMESTAMP WITH TIME ZONE`.
Example	`extract('hour' FROM TIMESTAMPTZ '1992-09-20 20:38:48')`
Result	`20`

`last_day(timestamptz)`

Description	The last day of the month.
Example	`last_day(TIMESTAMPTZ '1992-03-22 01:02:03.1234')`
Result	`1992-03-31`

`make_timestamptz(bigint, bigint, bigint, bigint, bigint, double, string)`

Description	The `TIMESTAMP WITH TIME ZONE` for the given parts and time zone.
Example	`make_timestamptz(1992, 9, 20, 15, 34, 27.123456, 'CET')`
Result	`1992-09-20 06:34:27.123456-07`

`make_timestamptz(bigint, bigint, bigint, bigint, bigint, double)`

Description	The `TIMESTAMP WITH TIME ZONE` for the given parts in the current time zone.
Example	`make_timestamptz(1992, 9, 20, 13, 34, 27.123456)`
Result	`1992-09-20 13:34:27.123456-07`

`make_timestamptz(microseconds)`

Description	The `TIMESTAMP WITH TIME ZONE` for the given µs since the epoch.
Example	`make_timestamptz(1667810584123456)`
Result	`2022-11-07 16:43:04.123456-08`

`strftime(timestamptz, format)`

Description	Converts a `TIMESTAMP WITH TIME ZONE` value to string according to the format string.
Example	`strftime(timestamptz '1992-01-01 20:38:40', '%a, %-d %B %Y - %I:%M:%S %p')`
Result	`Wed, 1 January 1992 - 08:38:40 PM`

`strptime(text, format)`

Description	Converts string to `TIMESTAMP WITH TIME ZONE` according to the format string if `%Z` is specified.
Example	`strptime('Wed, 1 January 1992 - 08:38:40 PST', '%a, %-d %B %Y - %H:%M:%S %Z')`

Result	`1992-01-01 08:38:40-08`

`time_bucket(bucket_width, timestamptz[, offset])`

Description	Truncate `timestamptz` to a grid of width `bucket_width`. The grid is anchored at `2000-01-01 00:00:00+00:00[ + offset]` when `bucket_width` is a number of months or coarser units, else `2000-01-03 00:00:00+00:00[ + offset]`. Note that `2000-01-03` is a Monday.
Example	`time_bucket(INTERVAL '10 minutes', TIMESTAMPTZ '1992-04-20 15:26:00-07', INTERVAL '5 minutes')`
Result	`1992-04-20 15:25:00-07`

`time_bucket(bucket_width, timestamptz[, origin])`

Description	Truncate `timestamptz` to a grid of width `bucket_width`. The grid is anchored at the `origin` timestamp, which defaults to `2000-01-01 00:00:00+00:00` when `bucket_width` is a number of months or coarser units, else `2000-01-03 00:00:00+00:00`. Note that `2000-01-03` is a Monday.
Example	`time_bucket(INTERVAL '2 weeks', TIMESTAMPTZ '1992-04-20 15:26:00-07', TIMESTAMPTZ '1992-04-01 00:00:00-07')`
Result	`1992-04-15 00:00:00-07`

`time_bucket(bucket_width, timestamptz[, timezone])`

Description	Truncate `timestamptz` to a grid of width `bucket_width`. The grid is anchored at the `origin` timestamp, which defaults to `2000-01-01 00:00:00` in the provided `timezone` when `bucket_width` is a number of months or coarser units, else `2000-01-03 00:00:00` in the provided `timezone`. The default timezone is `'UTC'`. Note that `2000-01-03` is a Monday.
Example	`time_bucket(INTERVAL '2 days', TIMESTAMPTZ '1992-04-20 15:26:00-07', 'Europe/Berlin')`
Result	`1992-04-19 15:00:00-07` (=`1992-04-20 00:00:00 Europe/Berlin`)

There are also dedicated extraction functions to get the subfields.

ICU Timestamp Table Functions

The table below shows the available table functions for `TIMESTAMP WITH TIME ZONE` types.

Name	Description
`generate_series(timestamptz, timestamptz, interval)`	Generate a table of timestamps in the closed range (including both the starting timestamp and the ending timestamp), stepping by the interval.
`range(timestamptz, timestamptz, interval)`	Generate a table of timestamps in the half open range (including the starting timestamp, but stopping before the ending timestamp), stepping by the interval.

> Infinite values are not allowed as table function bounds.

`generate_series(timestamptz, timestamptz, interval)`

Description	Generate a table of timestamps in the closed range (including both the starting timestamp and the ending timestamp), stepping by the interval.
Example	`generate_series(TIMESTAMPTZ '2001-04-10', TIMESTAMPTZ '2001-04-11', INTERVAL 30 MINUTE)`

`range(timestamptz, timestamptz, interval)`

Description	Generate a table of timestamps in the half open range (including the starting timestamp, but stopping before the ending timestamp), stepping by the interval.
Example	`range(TIMESTAMPTZ '2001-04-10', TIMESTAMPTZ '2001-04-11', INTERVAL 30 MINUTE)`

ICU Timestamp Without Time Zone Functions

The table below shows the ICU provided scalar functions that operate on plain `TIMESTAMP` values. These functions assume that the `TIMESTAMP` is a "local timestamp".

A local timestamp is effectively a way of encoding the part values from a time zone into a single value. They should be used with caution because the produced values can contain gaps and ambiguities thanks to daylight savings time. Often the same functionality can be implemented more reliably using the `struct` variant of the `date_part` function.

Name	Description
`current_localtime()`	Returns a `TIME` whose GMT bin values correspond to local time in the current time zone.
`current_localtimestamp()`	Returns a `TIMESTAMP` whose GMT bin values correspond to local date and time in the current time zone.
`localtime`	Synonym for the `current_localtime()` function call.
`localtimestamp`	Synonym for the `current_localtimestamp()` function call.
`timezone(text, timestamp)`	Use the date parts of the timestamp in GMT to construct a timestamp in the given time zone. Effectively, the argument is a "local" time.
`timezone(text, timestamptz)`	Use the date parts of the timestamp in the given time zone to construct a timestamp. Effectively, the result is a "local" time.

`current_localtime()`

Description	Returns a `TIME` whose GMT bin values correspond to local time in the current time zone.
Example	`current_localtime()`
Result	`08:47:56.497`

`current_localtimestamp()`

Description	Returns a TIMESTAMP whose GMT bin values correspond to local date and time in the current time zone.
Example	`current_localtimestamp()`
Result	`2022-12-17 08:47:56.497`

`localtime`

Description	Synonym for the `current_localtime()` function call.
Example	`localtime`
Result	`08:47:56.497`

`localtimestamp`

Description	Synonym for the `current_localtimestamp()` function call.
Example	`localtimestamp`
Result	`2022-12-17 08:47:56.497`

`timezone(text, timestamp)`

Description	Use the date parts of the timestamp in GMT to construct a timestamp in the given time zone. Effectively, the argument is a "local" time.
Example	`timezone('America/Denver', TIMESTAMP '2001-02-16 20:38:40')`
Result	`2001-02-16 19:38:40-08`

`timezone(text, timestamptz)`

Description	Use the date parts of the timestamp in the given time zone to construct a timestamp. Effectively, the result is a "local" time.
Example	`timezone('America/Denver', TIMESTAMPTZ '2001-02-16 20:38:40-05')`
Result	`2001-02-16 18:38:40`

At Time Zone

The `AT TIME ZONE` syntax is syntactic sugar for the (two argument) `timezone` function listed above:

```
SELECT TIMESTAMP '2001-02-16 20:38:40' AT TIME ZONE 'America/Denver' AS ts;
```

```
2001-02-16 19:38:40-08
```

```
SELECT TIMESTAMP WITH TIME ZONE '2001-02-16 20:38:40-05' AT TIME ZONE 'America/Denver' AS ts;
```

```
2001-02-16 18:38:40
```

Note that numeric timezones are not allowed:

```
SELECT TIMESTAMP '2001-02-16 20:38:40-05' AT TIME ZONE '0200' AS ts;
```

```
Not implemented Error: Unknown TimeZone '0200'
```

Infinities

Functions applied to infinite dates will either return the same infinite dates (e.g., `greatest`) or `NULL` (e.g., `date_part`) depending on what "makes sense". In general, if the function needs to examine the parts of the infinite temporal value, the result will be `NULL`.

Calendars

The ICU extension also supports non-Gregorian calendars. If such a calendar is current, then the display and binning operations will use that calendar.

Daylight Saving Time (DST) Transitions

When adding calendar intervals such as `INTERVAL '1 day'` to a `TIMESTAMPTZ`, the resulting local timestamp may fall on a non-existent time during daylight saving time transitions.

DuckDB follows PostgreSQL behavior and adjusts the result forward to the next valid timestamp.

Example:

```
SET timezone = 'Europe/Amsterdam';
```

```
SELECT TIMESTAMPTZ '2025-03-29 02:30:00+01' + INTERVAL '1 day';
```

```
2025-03-30 03:30:00+02
```

Union Functions

Name	Description
`union.tag`	Dot notation serves as an alias for `union_extract`.
`union_extract(union, 'tag')`	Extract the value with the named tags from the union. `NULL` if the tag is not currently selected.
`union_value(tag := any)`	Create a single member `UNION` containing the argument value. The tag of the value will be the bound variable name.
`union_tag(union)`	Retrieve the currently selected tag of the union as an Enum.

`union.tag`

Description	Dot notation serves as an alias for `union_extract`.
Example	`(union_value(k := 'hello')).k`
Result	`string`

`union_extract(union, 'tag')`

Description	Extract the value with the named tags from the union. `NULL` if the tag is not currently selected.
Example	`union_extract(s, 'k')`
Result	`hello`

`union_value(tag := any)`

Description	Create a single member `UNION` containing the argument value. The tag of the value will be the bound variable name.
Example	`union_value(k := 'hello')`
Result	`'hello'::UNION(k VARCHAR)`

`union_tag(union)`

Description	Retrieve the currently selected tag of the union as an Enum.
Example	`union_tag(union_value(k := 'foo'))`
Result	`'k'`

Utility Functions

Scalar Utility Functions

The functions below are difficult to categorize into specific function types and are broadly useful.

Name	Description
`alias(column)`	Return the name of the column.
`can_cast_implicitly(source_value, target_value)`	Whether or not we can implicitly cast from the types of the source value to the target value.
`checkpoint(database)`	Synchronize WAL with file for (optional) database without interrupting transactions.
`coalesce(expr, ...)`	Return the first expression that evaluates to a non-`NULL` value. Accepts 1 or more parameters. Each expression can be a column, literal value, function result, or many others.
`constant_or_null(arg1, arg2)`	If `arg2` is `NULL`, return `NULL`. Otherwise, return `arg1`.
`count_if(x)`	Aggregate function; rows contribute 1 if `x` is `true` or a non-zero number, else 0.
`create_sort_key(parameters...)`	Constructs a binary-comparable sort key based on a set of input parameters and sort qualifiers.
`current_catalog()`	Return the name of the currently active catalog. Default is memory.
`current_database()`	Return the name of the currently active database.
`current_query()`	Return the current query as a string.
`current_schema()`	Return the name of the currently active schema. Default is main.
`current_schemas(boolean)`	Return list of schemas. Pass a parameter of `true` to include implicit schemas.
`current_setting('setting_name')`	Return the current value of the configuration setting.
`currval('sequence_name')`	Return the current value of the sequence. Note that `nextval` must be called at least once prior to calling `currval`.
`error(message)`	Throws the given error `message`.

Name	Description
`equi_width_bins(min, max, bincount, nice := false)`	Returns the upper boundaries of a partition of the interval `[min, max]` into `bin_count` equal-sized subintervals (for use with, e.g., `histogram`). If `nice = true`, then `min`, `max` and `bincount` may be adjusted to produce more aesthetically pleasing results.
`force_checkpoint(database)`	Synchronize WAL with file for (optional) database interrupting transactions.
`gen_random_uuid()`	Return a random UUID similar to this: `eeccb8c5-9943-b2bb-bb5e-222f4e14b687`.
`getenv(var)`	Returns the value of the environment variable `var`. Only available in the command line client.
`hash(value)`	Returns a `UBIGINT` with a hash of `value`. The used hash function may change across DuckDB versions.
`icu_sort_key(string, collator)`	Surrogate sort key used to sort special characters according to the specific locale. Collator parameter is optional. Only available when the ICU extension is installed.
`if(a, b, c)`	Ternary conditional operator.
`ifnull(expr, other)`	A two-argument version of coalesce.
`is_histogram_other_bin(arg)`	Returns `true` when `arg` is the "catch-all element" of its datatype for the purpose of the `histogram_exact` function, which is equal to the "right-most boundary" of its datatype for the purpose of the `histogram` function.
`md5(string)`	Returns the MD5 hash of the `string` as a `VARCHAR`.
`md5_number(string)`	Returns the MD5 hash of the `string` as a `UHUGEINT`.
`md5_number_lower(string)`	Returns the lower 64-bit segment of the MD5 hash of the `string` as a `UBIGINT`.
`md5_number_upper(string)`	Returns the upper 64-bit segment of the MD5 hash of the `string` as a `UBIGINT`.
`nextval('sequence_name')`	Return the following value of the sequence.
`nullif(a, b)`	Return `NULL` if `a = b`, else return `a`. Equivalent to `CASE WHEN a = b THEN NULL ELSE a END`.
`parse_formatted_bytes(string)`	Parse a human-readable byte size string (e.g., `'16 KiB'`) into a `UBIGINT` number of bytes. Throws an error on invalid input.
`pg_typeof(expression)`	Returns the lower case name of the data type of the result of the expression. For PostgreSQL compatibility.
`query(`*`query_string`*`)`	Table function that parses and executes the query defined in *`query_string`*. Only constant strings are allowed. Warning: this function allows invoking arbitrary queries, potentially altering the database state.
`query_table(`*`tbl_name`*`)`	Table function that returns the table given in *`tbl_name`*.
`query_table(`*`tbl_names`*`, [`*`by_name`*`])`	Table function that returns the union of tables given in *`tbl_names`*. If the optional *`by_name`* parameter is set to `true`, it uses `UNION ALL BY NAME` semantics.
`read_blob(source)`	Returns the content from `source` (a filename, a list of filenames, or a glob pattern) as a `BLOB`. See the `read_blob` guide for more details.
`read_text(source)`	Returns the content from `source` (a filename, a list of filenames, or a glob pattern) as a `VARCHAR`. The file content is first validated to be valid UTF-8. If `read_text` attempts to read a file with invalid UTF-8 an error is thrown suggesting to use `read_blob` instead. See the `read_text` guide for more details.
`replace_type(value, source_type, target_type)`	Recursively casts every field of `value` that has type `source_type` to `target_type`. The types are supplied as `NULL`-typed values, e.g., `NULL::VARCHAR`.
`sha1(string)`	Returns a `VARCHAR` with the SHA-1 hash of the `string`.
`sha256(string)`	Returns a `VARCHAR` with the SHA-256 hash of the `string`.
`sleep_ms(milliseconds)`	Pause execution for the specified number of milliseconds. Returns `NULL`.

Name	Description
`stats(expression)`	Returns a string with statistics about the expression. Expression can be a column, constant, or SQL expression.
`txid_current()`	Returns the current transaction's identifier, a `BIGINT` value. It will assign a new one if the current transaction does not have one already.
`typeof(expression)`	Returns the name of the data type of the result of the expression.
`uuid()`	Return a random UUID (UUIDv4) similar to this: `eeccb8c5-9943-b2bb-bb5e-222f4e14b687`.
`uuidv4()`	Return a random UUID (UUIDv4) similar to this: `eeccb8c5-9943-b2bb-bb5e-222f4e14b687`.
`uuidv7()`	Return a random UUIDv7 similar to this: `81964ebe-00b1-7e1d-b0f9-43c29b6fb8f5`.
`uuid_extract_timestamp(uuidv7)`	Extracts `TIMESTAMP WITH TIME ZONE` from a UUIDv7 value.
`uuid_extract_version(uuid)`	Extracts UUID version (4 or 7).
`version()`	Return the currently active version of DuckDB in this format.

`alias(column)`

Description	Return the name of the column.
Example	`alias(column1)`
Result	`column1`

`can_cast_implicitly(source_value, target_value)`

Description	Whether or not we can implicitly cast from the types of the source value to the target value.
Example	`can_cast_implicitly(1::BIGINT, 1::SMALLINT)`
Result	`false`

`checkpoint(database)`

Description	Synchronize WAL with file for (optional) database without interrupting transactions.
Example	`checkpoint(my_db)`
Result	success Boolean

`coalesce(expr, ...)`

Description	Return the first expression that evaluates to a non-`NULL` value. Accepts 1 or more parameters. Each expression can be a column, literal value, function result, or many others.
Example	`coalesce(NULL, NULL, 'default_string')`
Result	`default_string`

constant_or_null(arg1, arg2)

Description	If `arg2` is `NULL`, return `NULL`. Otherwise, return `arg1`.
Example	`constant_or_null(42, NULL)`
Result	`NULL`

count_if(x)

Description	Aggregate function; rows contribute 1 if `x` is `true` or a non-zero number, else 0.
Example	`count_if(42)`
Result	`1`

create_sort_key(parameters...)

Description	Constructs a binary-comparable sort key based on a set of input parameters and sort qualifiers.
Example	`create_sort_key('abc', 'ASC NULLS FIRST');`
Result	`\x02bcd\x00`

current_catalog()

Description	Return the name of the currently active catalog. Default is memory.
Example	`current_catalog()`
Result	`memory`

current_database()

Description	Return the name of the currently active database.
Example	`current_database()`
Result	`memory`

current_query()

Description	Return the current query as a string.
Example	`current_query()`
Result	`SELECT current_query();`

current_schema()

Description	Return the name of the currently active schema. Default is main.
Example	`current_schema()`

Result	`main`

`current_schemas(boolean)`

Description	Return list of schemas. Pass a parameter of `true` to include implicit schemas.
Example	`current_schemas(true)`
Result	`['temp', 'main', 'pg_catalog']`

`current_setting('setting_name')`

Description	Return the current value of the configuration setting.
Example	`current_setting('access_mode')`
Result	`automatic`

`currval('sequence_name')`

Description	Return the current value of the sequence. Note that `nextval` must be called at least once prior to calling `currval`.
Example	`currval('my_sequence_name')`
Result	`1`

`error(message)`

Description	Throws the given error `message`.
Example	`error('access_mode')`

`equi_width_bins(min, max, bincount, nice := false)`

Description	Returns the upper boundaries of a partition of the interval `[min, max]` into `bin_count` equal-sized subintervals (for use with, e.g., `histogram`). If `nice = true`, then `min`, `max` and `bincount` may be adjusted to produce more aesthetically pleasing results.
Example	`equi_width_bins(0.1, 2.7, 4, true)`
Result	`[0.5, 1.0, 1.5, 2.0, 2.5, 3.0]`

`force_checkpoint(database)`

Description	Synchronize WAL with file for (optional) database interrupting transactions.
Example	`force_checkpoint(my_db)`
Result	success Boolean

`gen_random_uuid()`

Description	Return a random UUID (UUIDv4) similar to this: `eeccb8c5-9943-b2bb-bb5e-222f4e14b687`.
Example	`gen_random_uuid()`
Result	various

`getenv(var)`

Description	Returns the value of the environment variable `var`. Only available in the command line client.
Example	`getenv('HOME')`
Result	`/path/to/user/home`

`hash(value)`

Description	Returns a `UBIGINT` with the hash of the `value`. The used hash function may change across DuckDB versions.
Example	`hash('🦆')`
Result	`2595805878642663834`

`icu_sort_key(string, collator)`

Description	Surrogate sort key used to sort special characters according to the specific locale. Collator parameter is optional. Only available when the ICU extension is installed.
Example	`icu_sort_key('ö', 'DE')`
Result	`460145960106`

`if(a, b, c)`

Description	Ternary conditional operator; returns b if a, else returns c. Equivalent to `CASE WHEN a THEN b ELSE c END`.
Example	`if(2 > 1, 3, 4)`
Result	`3`

`ifnull(expr, other)`

Description	A two-argument version of coalesce.
Example	`ifnull(NULL, 'default_string')`
Result	`default_string`

`is_histogram_other_bin(arg)`

Description	Returns `true` when `arg` is the ”catch-all element” of its datatype for the purpose of the `histogram_exact` function, which is equal to the ”right-most boundary” of its datatype for the purpose of the `histogram` function.
Example	`is_histogram_other_bin('')`
Result	`true`

`md5(string)`

Description	Returns the MD5 hash of the `string` as a `VARCHAR`.
Example	`md5('abc')`
Result	`900150983cd24fb0d6963f7d28e17f72`

`md5_number(string)`

Description	Returns the MD5 hash of the `string` as a `UHUGEINT`.
Example	`md5_number('abc')`
Result	`152195979970564155685860391459828531600`

`md5_number_lower(string)`

Description	Returns the lower 8 bytes of the MD5 hash of `string` as a `UBIGINT`.
Example	`md5_number_lower('abc')`
Result	`8250560606382298838`

`md5_number_upper(string)`

Description	Returns the upper 8 bytes of the MD5 hash of `string` as a `UBIGINT`.
Example	`md5_number_upper('abc')`
Result	`12704604231530709392`

`nextval('sequence_name')`

Description	Return the following value of the sequence.
Example	`nextval('my_sequence_name')`
Result	2

`nullif(a, b)`

Description	Return `NULL` if a = b, else return a. Equivalent to `CASE WHEN a = b THEN NULL ELSE a END`.
Example	`nullif(1+1, 2)`

Result	`NULL`

`parse_formatted_bytes(string)`

Description	Parse a human-readable byte size string (e.g., `'16 KiB'`) into a `UBIGINT` number of bytes. Throws an error on invalid input.
Example	`parse_formatted_bytes('1.5 GiB')`
Result	`1610612736`

`pg_typeof(expression)`

Description	Returns the lower case name of the data type of the result of the expression. For PostgreSQL compatibility.
Example	`pg_typeof('abc')`
Result	`varchar`

`query(query_string)`

Description	Table function that parses and executes the query defined in `query_string`. Only constant strings are allowed. Warning: this function allows invoking arbitrary queries, potentially altering the database state.
Example	`query('SELECT 42 AS x')`
Result	`42`

`query_table(tbl_name)`

Description	Table function that returns the table given in `tbl_name`.
Example	`query_table('t1')`
Result	(the rows of `t1`)

`query_table(tbl_names, [by_name])`

Description	Table function that returns the union of tables given in `tbl_names`. If the optional `by_name` parameter is set to `true`, it uses `UNION ALL BY NAME` semantics.
Example	`query_table(['t1', 't2'])`
Result	(the union of the two tables)

`read_blob(source)`

Description	Returns the content from `source` (a filename, a list of filenames, or a glob pattern) as a BLOB. See the `read_blob` guide for more details.
Example	`read_blob('hello.bin')`
Result	`hello\x0A`

`read_text(source)`

Description	Returns the content from `source` (a filename, a list of filenames, or a glob pattern) as a VARCHAR. The file content is first validated to be valid UTF-8. If `read_text` attempts to read a file with invalid UTF-8 an error is thrown suggesting to use `read_blob` instead. See the `read_text` guide for more details.
Example	`read_text('hello.txt')`
Result	`hello\n`

`replace_type(value, source_type, target_type)`

Description	Recursively casts every field of `value` that has type `source_type` to `target_type`. The source and target types are supplied as `NULL`-typed values, e.g., `NULL::VARCHAR`. Useful for converting the field types of a deeply nested value (e.g., a `STRUCT` or `LIST`) in one call.
Example	`replace_type([{'a': '42'}], NULL::VARCHAR, NULL::INTEGER)`
Result	`[{'a': 42}]`

`sha1(string)`

Description	Returns a VARCHAR with the SHA-1 hash of the `string`.
Example	`sha1('🦆')`
Result	`949bf843dc338be348fb9525d1eb535d31241d76`

`sha256(string)`

Description	Returns a VARCHAR with the SHA-256 hash of the `string`.
Example	`sha256('🦆')`
Result	`d7a5c5e0d1d94c32218539e7e47d4ba9c3c7b77d61332fb60d633dde89e473fb`

`sleep_ms(milliseconds)`

Description	Pause execution for the specified number of milliseconds. Returns `NULL`.
Example	`sleep_ms(500)`
Result	`NULL`

`stats(expression)`

Description	Returns a string with statistics about the expression. Expression can be a column, constant, or SQL expression.
Example	`stats(5)`
Result	`'[Min: 5, Max: 5][Has Null: false]'`

`txid_current()`

Description	Returns the current transaction's identifier, a `BIGINT` value. It will assign a new one if the current transaction does not have one already.
Example	`txid_current()`
Result	various

`typeof(expression)`

Description	Returns the name of the data type of the result of the expression.
Example	`typeof('abc')`
Result	VARCHAR

`uuid()`

Description	Return a random UUID (UUIDv4) similar to this: `eeccb8c5-9943-b2bb-bb5e-222f4e14b687`.
Example	`uuid()`
Result	various

`uuidv4()`

Description	Return a random UUID (UUIDv4) similar to this: `eeccb8c5-9943-b2bb-bb5e-222f4e14b687`.
Example	`uuidv4()`
Result	various

`uuidv7()`

Description	Return a random UUIDv7 similar to this: `81964ebe-00b1-7e1d-b0f9-43c29b6fb8f5`.
Example	`uuidv7()`
Result	various

`uuid_extract_timestamp(uuidv7)`

Description	Extracts `TIMESTAMP WITH TIME ZONE` from a UUIDv7 value.
Example	`uuid_extract_timestamp(uuidv7())`
Result	`2025-04-19 15:51:20.07+00`

`uuid_extract_version(uuid)`

Description	Extracts UUID version (4 or 7).
Example	`uuid_extract_version(uuidv7())`
Result	7

`version()`

Description	Return the currently active version of DuckDB in this format.
Example	`version()`
Result	various

Utility Table Functions

A table function is used in place of a table in a `FROM` clause.

Name	Description
`glob(search_path)`	Return filenames found at the location indicated by the *search_path* in a single column named `file`. The *search_path* may contain glob pattern matching syntax.
`repeat_row(varargs, num_rows)`	Returns a table with `num_rows` rows, each containing the fields defined in `varargs`.

`glob(search_path)`

Description	Return filenames found at the location indicated by the *search_path* in a single column named `file`. The *search_path* may contain glob pattern matching syntax.
Example	`glob('*')`
Result	(table of filenames)

`repeat_row(varargs, num_rows)`

Description	Returns a table with `num_rows` rows, each containing the fields defined in `varargs`.
Example	`repeat_row(1, 2, 'foo', num_rows = 3)`
Result	3 rows of `1, 2, 'foo'`

Window Functions

DuckDB supports window functions, which can use multiple rows to calculate a value for each row. Window functions are blocking operators, i.e., they require their entire input to be buffered, making them one of the most memory-intensive operators in SQL.

Window functions are available in SQL since SQL:2003 and are supported by major SQL database systems.

Examples

Generate a `row_number` column to enumerate rows:

```
SELECT row_number() OVER ()
FROM sales;
```

> **Tip.** If you only need a number for each row in a table, you can use the `rowid` pseudocolumn.

Generate a `row_number` column to enumerate rows, ordered by `time`:

```
SELECT row_number() OVER (ORDER BY time)
FROM sales;
```

Generate a `row_number` column to enumerate rows, ordered by `time` and partitioned by `region`:

```
SELECT row_number() OVER (PARTITION BY region ORDER BY time)
FROM sales;
```

Compute the difference between the current and the previous-by-`time` `amount`:

```
SELECT amount - lag(amount) OVER (ORDER BY time)
FROM sales;
```

Compute the percentage of the total `amount` of sales per `region` for each row:

```
SELECT amount / sum(amount) OVER (PARTITION BY region)
FROM sales;
```

Syntax

Window functions can only be used in the `SELECT` clause. To share `OVER` specifications between functions, use the statement's `WINDOW` clause and use the `OVER <window_name>{:.language-sql .highlight}` syntax.

General-Purpose Window Functions

The table below shows the available general window functions.

Name	Description
`cume_dist([ORDER BY ordering])`	The cumulative distribution: (number of partition rows preceding or peer with current row) / total partition rows.
`dense_rank()`	The rank of the current row *without gaps;* this function counts peer groups.
`fill(expr [ ORDER BY ordering])`	Fill in missing values using linear interpolation with `ORDER BY` as the X-axis.
`first_value(expr[ ORDER BY ordering][ IGNORE NULLS])`	Returns `expr` evaluated at the row that is the first row (with a non-null value of `expr` if `IGNORE NULLS` is set) of the window frame.

Name	Description
`lag(expr[, offset[, default]][ ORDER BY ordering][ IGNORE NULLS])`	Returns `expr` evaluated at the row that is `offset` rows (among rows with a non-null value of `expr` if `IGNORE NULLS` is set) before the current row within the window frame; if there is no such row, instead return `default` (which must be of the same type as `expr`). Both `offset` and `default` are evaluated with respect to the current row. If omitted, `offset` defaults to `1` and default to `NULL`.
`last_value(expr[ ORDER BY ordering][ IGNORE NULLS])`	Returns `expr` evaluated at the row that is the last row (among rows with a non-null value of `expr` if `IGNORE NULLS` is set) of the window frame.
`lead(expr[, offset[, default]][ ORDER BY ordering][ IGNORE NULLS])`	Returns `expr` evaluated at the row that is `offset` rows after the current row (among rows with a non-null value of `expr` if `IGNORE NULLS` is set) within the window frame; if there is no such row, instead return `default` (which must be of the same type as `expr`). Both `offset` and `default` are evaluated with respect to the current row. If omitted, `offset` defaults to `1` and default to `NULL`.
`nth_value(expr, nth[ ORDER BY ordering][ IGNORE NULLS])`	Returns `expr` evaluated at the nth row (among rows with a non-null value of `expr` if `IGNORE NULLS` is set) of the window frame (counting from 1); `NULL` if no such row.
`ntile(num_buckets[ ORDER BY ordering])`	An integer ranging from 1 to `num_buckets`, dividing the partition as equally as possible.
`percent_rank([ORDER BY ordering])`	The relative rank of the current row: `(rank() - 1) / (total partition rows - 1)`.
`rank([ORDER BY ordering])`	The rank of the current row *with gaps;* same as `row_number` of its first peer.
`row_number([ORDER BY ordering])`	The number of the current row within the partition, counting from 1.

`cume_dist([ORDER BY ordering])`

Description	The cumulative distribution: (number of partition rows preceding or peer with current row) / total partition rows. If an `ORDER BY` clause is specified, the distribution is computed within the frame using the provided ordering instead of the frame ordering.
Return type	`DOUBLE`
Example	`cume_dist()`

`dense_rank()`

Description	The rank of the current row *without gaps;* this function counts peer groups.
Return type	`BIGINT`
Example	`dense_rank()`
Aliases	`rank_dense()`

`fill(expr[ ORDER BY ordering])`

Description	Replaces NULL values of expr with a linear interpolation based on the closest non-NULL values and the sort values. Both values must support arithmetic and there must be only one ordering key. For missing values at the ends, linear extrapolation is used. Failure to interpolate results in the NULL value being retained.
Return type	Same type as expr
Example	fill(column)

first_value(expr[ORDER BY ordering][IGNORE NULLS])

Description	Returns expr evaluated at the row that is the first row (with a non-null value of expr if IGNORE NULLS is set) of the window frame. If an ORDER BY clause is specified, the first row number is computed within the frame using the provided ordering instead of the frame ordering.
Return type	Same type as expr
Example	first_value(column)

lag(expr[, offset[, default]][ORDER BY ordering][IGNORE NULLS])

Description	Returns expr evaluated at the row that is offset rows (among rows with a non-null value of expr if IGNORE NULLS is set) before the current row within the window frame; if there is no such row, instead return default (which must be of the same type as expr). Both offset and default are evaluated with respect to the current row. If omitted, offset defaults to 1 and default to NULL. If an ORDER BY clause is specified, the lagged row number is computed within the frame using the provided ordering instead of the frame ordering.
Return type	Same type as expr
Example	lag(column, 3, 0)

last_value(expr[ORDER BY ordering][IGNORE NULLS])

Description	Returns expr evaluated at the row that is the last row (among rows with a non-null value of expr if IGNORE NULLS is set) of the window frame. If omitted, offset defaults to 1 and default to NULL. If an ORDER BY clause is specified, the last row is determined within the frame using the provided ordering instead of the frame ordering.
Return type	Same type as expr
Example	last_value(column)

lead(expr[, offset[, default]][ORDER BY ordering][IGNORE NULLS])

Description	Returns expr evaluated at the row that is offset rows after the current row (among rows with a non-null value of expr if IGNORE NULLS is set) within the window frame; if there is no such row, instead return default (which must be of the same type as expr). Both offset and default are evaluated with respect to the current row. If omitted, offset defaults to 1 and default to NULL. If an ORDER BY clause is specified, the leading row number is computed within the frame using the provided ordering instead of the frame ordering.
Return type	Same type as expr

Example	`lead(column, 3, 0)`

`nth_value(expr, nth[ ORDER BY ordering][ IGNORE NULLS])`

Description	Returns `expr` evaluated at the nth row (among rows with a non-null value of `expr` if `IGNORE NULLS` is set) of the window frame (counting from 1); `NULL` if no such row. If an `ORDER BY` clause is specified, the nth row number is computed within the frame using the provided ordering instead of the frame ordering.
Return type	Same type as `expr`
Example	`nth_value(column, 2)`

`ntile(num_buckets[ ORDER BY ordering])`

Description	An integer ranging from 1 to `num_buckets`, dividing the partition as equally as possible. If an `ORDER BY` clause is specified, the ntile is computed within the frame using the provided ordering instead of the frame ordering.
Return type	`BIGINT`
Example	`ntile(4)`

`percent_rank([ORDER BY ordering])`

Description	The relative rank of the current row: `(rank() - 1) / (total partition rows - 1)`. If an `ORDER BY` clause is specified, the relative rank is computed within the frame using the provided ordering instead of the frame ordering.
Return type	`DOUBLE`
Example	`percent_rank()`

`rank([ORDER BY ordering])`

Description	The rank of the current row *with gaps*; same as `row_number` of its first peer. If an `ORDER BY` clause is specified, the rank is computed within the frame using the provided ordering instead of the frame ordering.
Return type	`BIGINT`
Example	`rank()`

`row_number([ORDER BY ordering])`

Description	The number of the current row within the partition, counting from 1. If an `ORDER BY` clause is specified, the row number is computed within the frame using the provided ordering instead of the frame ordering.
Return type	`BIGINT`
Example	`row_number()`

Aggregate Window Functions

All aggregate functions can be used in a windowing context, including the optional `FILTER` clause. The `first` and `last` aggregate functions are shadowed by the respective general-purpose window functions, with the minor consequence that the `FILTER` clause is not available for these but `IGNORE NULLS` is.

DISTINCT Arguments

All aggregate window functions support using a `DISTINCT` clause for the arguments. When the `DISTINCT` clause is provided, only distinct values are considered in the computation of the aggregate. This is typically used in combination with the `COUNT` aggregate to get the number of distinct elements; but it can be used together with any aggregate function in the system. There are some aggregates that are insensitive to duplicate values (e.g., `min`, `max`) and for them this clause is parsed and ignored.

```
-- Count the number of distinct users at a given point in time
SELECT count(DISTINCT name) OVER (ORDER BY time) FROM sales;
-- Concatenate those distinct users into a list
SELECT list(DISTINCT name) OVER (ORDER BY time) FROM sales;
```

ORDER BY Arguments

All aggregate window functions support using an `ORDER BY` argument clause that is *different* from the window ordering. When the `ORDER BY` argument clause is provided, the values being aggregated are sorted before applying the function. Usually this is not important, but there are some order-sensitive aggregates that can have indeterminate results (e.g., `mode`, `list` and `string_agg`). These can be made deterministic by ordering the arguments. For order-insensitive aggregates, this clause is parsed and ignored.

```
-- Compute the modal value up to each time, breaking ties in favor of the most recent value.
SELECT mode(value ORDER BY time DESC) OVER (ORDER BY time) FROM sales;
```

The SQL standard does not provide for using `ORDER BY` with general-purpose window functions, but we have extended all of these functions (except `dense_rank`) to accept this syntax and use framing to restrict the range that the secondary ordering applies to.

```
-- Compare each athlete's time in an event with the best time to date
SELECT event, date, athlete, time
    first_value(time ORDER BY time DESC) OVER w AS record_time,
    first_value(athlete ORDER BY time DESC) OVER w AS record_athlete,
FROM meet_results
WINDOW w AS (PARTITION BY event ORDER BY datetime)
ORDER BY ALL
```

Note that there is no comma separating the arguments from the `ORDER BY` clause.

Nulls

All general-purpose window functions that accept `IGNORE NULLS` respect nulls by default. This default behavior can optionally be made explicit via `RESPECT NULLS`.

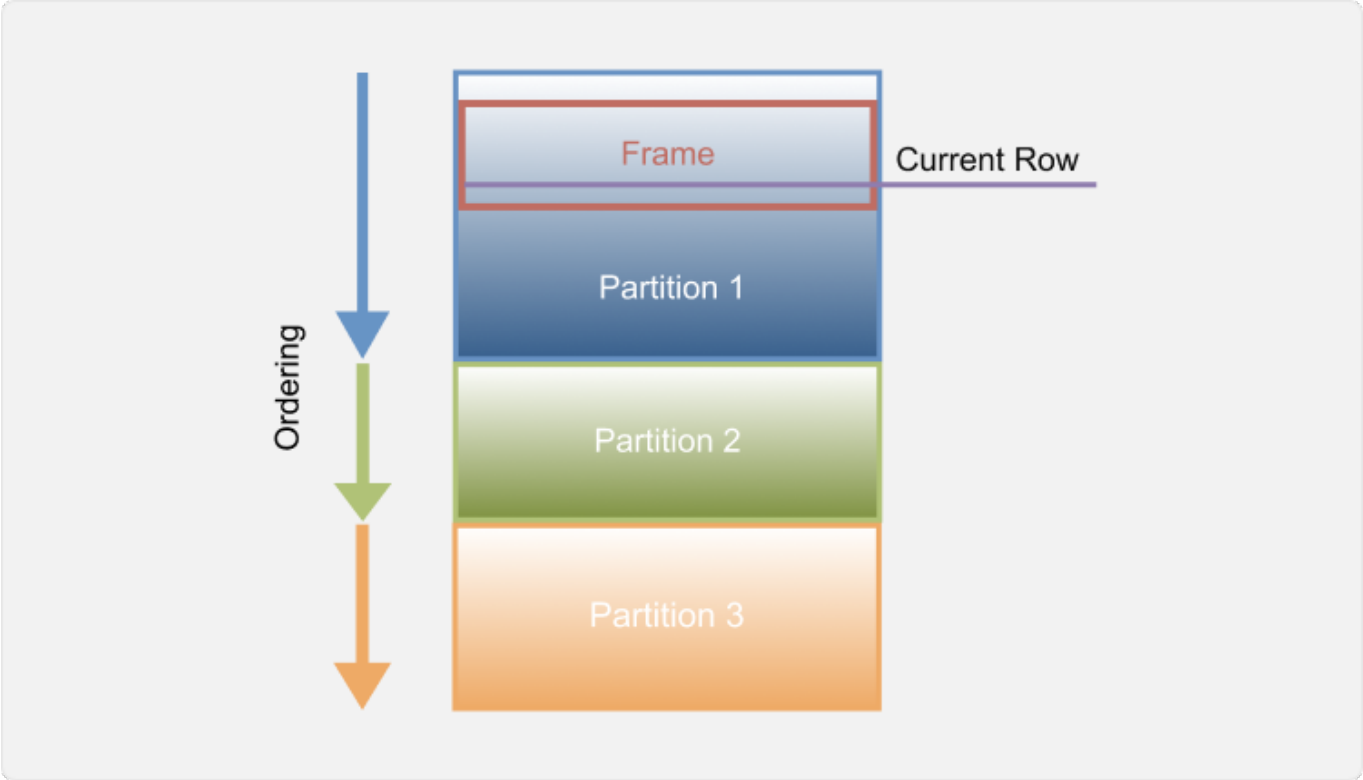
In contrast, all aggregate window functions (except for `list` and its aliases, which can be made to ignore nulls via a `FILTER`) ignore nulls and do not accept `RESPECT NULLS`. For example, `sum(column) OVER (ORDER BY time) AS cumulativeColumn` computes a cumulative sum where rows with a `NULL` value of `column` have the same value of `cumulativeColumn` as the row that precedes them.

Evaluation

Windowing works by breaking a relation up into independent *partitions*, *ordering* those partitions, and then computing a new column for each row as a function of the nearby values. Some window functions depend only on the partition boundary and the ordering, but a few (including all the aggregates) also use a *frame*. Frames are specified as a number of rows on either side (*preceding* or *following*) of the

current row. The distance can be specified as a number of *rows*, as a *range* of values using the partition's ordering value and a distance, or as a number of *groups* (sets of rows with the same sort value).

The full syntax is shown in the diagram at the top of the page, and this diagram visually illustrates computation environment:



Partition and Ordering

Partitioning breaks the relation up into independent, unrelated pieces. Partitioning is optional, and if none is specified then the entire relation is treated as a single partition. Window functions cannot access values outside of the partition containing the row they are being evaluated at.

Ordering is also optional, but without it the results of general-purpose window functions and order-sensitive aggregate functions, and the order of framing are not well-defined. Each partition is ordered using the same ordering clause.

Here is a table of power generation data, available as a CSV file (`power-plant-generation-history.csv`). To load the data, run:

```
CREATE TABLE "Generation History" AS
    FROM 'power-plant-generation-history.csv';
```

After partitioning by plant and ordering by date, it will have this layout:

Plant	Date	MWh
Boston	2019-01-02	564337
Boston	2019-01-03	507405
Boston	2019-01-04	528523
Boston	2019-01-05	469538
Boston	2019-01-06	474163
Boston	2019-01-07	507213
Boston	2019-01-08	613040

Plant	Date	MWh
Boston	2019-01-09	582588
Boston	2019-01-10	499506
Boston	2019-01-11	482014
Boston	2019-01-12	486134
Boston	2019-01-13	531518
Worcester	2019-01-02	118860
Worcester	2019-01-03	101977
Worcester	2019-01-04	106054
Worcester	2019-01-05	92182
Worcester	2019-01-06	94492
Worcester	2019-01-07	99932
Worcester	2019-01-08	118854
Worcester	2019-01-09	113506
Worcester	2019-01-10	96644
Worcester	2019-01-11	93806
Worcester	2019-01-12	98963
Worcester	2019-01-13	107170

In what follows, we shall use this table (or small sections of it) to illustrate various pieces of window function evaluation.

The simplest window function is `row_number()`. This function just computes the 1-based row number within the partition using the query:

```
SELECT
    "Plant",
    "Date",
    row_number() OVER (PARTITION BY "Plant" ORDER BY "Date") AS "Row"
FROM "Generation History"
ORDER BY 1, 2;
```

The result will be the following:

Plant	Date	Row
Boston	2019-01-02	1
Boston	2019-01-03	2
Boston	2019-01-04	3
...	...	...
Worcester	2019-01-02	1
Worcester	2019-01-03	2
Worcester	2019-01-04	3
...	...	...

Note that even though the function is computed with an ORDER BY clause, the result does not have to be sorted, so the SELECT also needs to be explicitly sorted if that is desired.

Framing

Framing specifies a set of rows relative to each row where the function is evaluated. The distance from the current row is given as an expression either `PRECEDING` or `FOLLOWING` the current row in the order specified by the `ORDER BY` clause in the `OVER` specification. This distance can either be specified as an integral number of `ROWS` or `GROUPS`, or as a `RANGE` delta expression. It is invalid for a frame to start after it ends. For a `RANGE` specification, there must be only one ordering expression and it must support subtraction unless only the sentinel boundary values `UNBOUNDED PRECEDING` / `UNBOUNDED FOLLOWING` / `CURRENT ROW` are used. Using the `EXCLUDE` clause, rows comparing equal to the current row in the specified ordering expression (so-called peers) can be excluded from the frame.

The default frame is unbounded (i.e., the entire partition) when no `ORDER BY` clause is present and `RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW` when an `ORDER BY` clause is present. By default, the `CURRENT ROW` boundary value (but not the `CURRENT ROW` in the `EXCLUDE` clause) means the current row and all its peers when `RANGE` or `GROUP` framing are used but it means only the current row when `ROWS` framing is used.

ROWS Framing Here is a simple `ROW` frame query, using an aggregate function:

```
SELECT points,
    sum(points) OVER (
        ROWS BETWEEN 1 PRECEDING
                 AND 1 FOLLOWING) AS we
FROM results;
```

This query computes the `sum` of each point and the points on either side of it:

POINTS	WE
10	18
8	30
12	29
9	30
9	27
9	23
5	21
7	12

POINTS	WE
10	18
8	30
12	29
9	30
9	27
9	23
5	21
7	12

POINTS	WE
10	18
8	30
12	29
9	30
9	27
9	23
5	21
7	12

POINTS	WE
10	18
8	30
12	29
9	30
9	27
9	23
5	21
7	12

Notice that at the edge of the partition, there are only two values added together. This is because frames are cropped to the edge of the partition.

RANGE Framing Returning to the power data, suppose the data is noisy. We might want to compute a 7 day moving average for each plant to smooth out the noise. To do this, we can use this window query:

```
SELECT "Plant", "Date",
    avg("MWh") OVER (
        PARTITION BY "Plant"
        ORDER BY "Date" ASC
        RANGE BETWEEN INTERVAL 3 DAYS PRECEDING
                  AND INTERVAL 3 DAYS FOLLOWING)
        AS "MWh 7-day Moving Average"
FROM "Generation History"
ORDER BY 1, 2;
```

This query partitions the data by `Plant` (to keep the different power plants' data separate), orders each plant's partition by `Date` (to put the energy measurements next to each other), and uses a `RANGE` frame of three days on either side of each day for the `avg` (to handle any missing days). This is the result:

Plant	Date	MWh 7-day Moving Average
Boston	2019-01-02	517450.75
Boston	2019-01-03	508793.20
Boston	2019-01-04	508529.83
…	…	…
Boston	2019-01-13	499793.00
Worcester	2019-01-02	104768.25
Worcester	2019-01-03	102713.00
Worcester	2019-01-04	102249.50
…	…	…

GROUPS Framing The third type of framing counts *groups* of rows relative the current row. A *group* in this framing is a set of values with identical ORDER BY values. If we assume that power is being generated on every day, we can use GROUPS framing to compute the moving average of all power generated in the system without having to resort to date arithmetic:

```
SELECT "Date", "Plant",
    avg("MWh") OVER (
        ORDER BY "Date" ASC
        GROUPS BETWEEN 3 PRECEDING
                   AND 3 FOLLOWING)
        AS "MWh 7-day Moving Average"
FROM "Generation History"
ORDER BY 1, 2;
```

Date	Plant	MWh 7-day Moving Average
2019-01-02	Boston	311109.500
2019-01-02	Worcester	311109.500
2019-01-03	Boston	305753.100
2019-01-03	Worcester	305753.100
2019-01-04	Boston	305389.667
2019-01-04	Worcester	305389.667
…	…	…
2019-01-12	Boston	309184.900
2019-01-12	Worcester	309184.900
2019-01-13	Boston	299469.375
2019-01-13	Worcester	299469.375

Notice how the values for each date are the same.

EXCLUDE Clause EXCLUDE is an optional modifier to the frame clause for excluding rows around the CURRENT ROW. This is useful when you want to compute some aggregate value of nearby rows to see how the current row compares to it.

In the following example, we want to know how an athlete's time in an event compares to the average of all the times recorded for their event within ±10 days:

```
SELECT
    event,
    date,
    athlete,
    avg(time) OVER w AS recent,
FROM results
WINDOW w AS (
    PARTITION BY event
    ORDER BY date
    RANGE BETWEEN INTERVAL 10 DAYS PRECEDING AND INTERVAL 10 DAYS FOLLOWING
        EXCLUDE CURRENT ROW
)
ORDER BY event, date, athlete;
```

There are four options for EXCLUDE that specify how to treat the current row:

- CURRENT ROW – exclude just the current row
- GROUP – exclude the current row and all its "peers" (rows that have the same ORDER BY value)
- TIES – exclude all peer rows, but *not* the current row (this makes a hole on either side)
- NO OTHERS – don't exclude anything (the default)

Exclusion is implemented for both windowed aggregates as well as for the `first`, `last` and `nth_value` functions.

`WINDOW` Clauses

Multiple different OVER clauses can be specified in the same SELECT, and each will be computed separately. Often, however, we want to use the same layout for multiple window functions. The WINDOW clause can be used to define a *named* window that can be shared between multiple window functions:

```
SELECT "Plant", "Date",
    min("MWh") OVER seven AS "MWh 7-day Moving Minimum",
    avg("MWh") OVER seven AS "MWh 7-day Moving Average",
    max("MWh") OVER seven AS "MWh 7-day Moving Maximum"
FROM "Generation History"
WINDOW seven AS (
    PARTITION BY "Plant"
    ORDER BY "Date" ASC
    RANGE BETWEEN INTERVAL 3 DAYS PRECEDING
              AND INTERVAL 3 DAYS FOLLOWING)
ORDER BY 1, 2;
```

The three window functions will also share the data layout, which will improve performance.

Multiple windows can be defined in the same WINDOW clause by comma-separating them:

```
SELECT "Plant", "Date",
    min("MWh") OVER seven AS "MWh 7-day Moving Minimum",
    avg("MWh") OVER seven AS "MWh 7-day Moving Average",
    max("MWh") OVER seven AS "MWh 7-day Moving Maximum",
    min("MWh") OVER three AS "MWh 3-day Moving Minimum",
    avg("MWh") OVER three AS "MWh 3-day Moving Average",
    max("MWh") OVER three AS "MWh 3-day Moving Maximum"
FROM "Generation History"
WINDOW
    seven AS (
        PARTITION BY "Plant"
        ORDER BY "Date" ASC
        RANGE BETWEEN INTERVAL 3 DAYS PRECEDING
                  AND INTERVAL 3 DAYS FOLLOWING),
    three AS (
```

```
        PARTITION BY "Plant"
        ORDER BY "Date" ASC
        RANGE BETWEEN INTERVAL 1 DAYS PRECEDING
        AND INTERVAL 1 DAYS FOLLOWING)
ORDER BY 1, 2;
```

The queries above do not use a number of clauses commonly found in select statements, like `WHERE`, `GROUP BY`, etc. For more complex queries you can find where `WINDOW` clauses fall in the canonical order of the `SELECT statement`.

Filtering the Results of Window Functions Using `QUALIFY`

Window functions are executed after the `WHERE` and `HAVING` clauses have been already evaluated, so it's not possible to use these clauses to filter the results of window functions The `QUALIFY clause` avoids the need for a subquery or `WITH clause` to perform this filtering.

Box and Whisker Queries

All aggregates can be used as windowing functions, including the complex statistical functions. These function implementations have been optimized for windowing, and we can use the window syntax to write queries that generate the data for moving box-and-whisker plots:

```
SELECT "Plant", "Date",
    min("MWh") OVER seven AS "MWh 7-day Moving Minimum",
    quantile_cont("MWh", [0.25, 0.5, 0.75]) OVER seven
        AS "MWh 7-day Moving IQR",
    max("MWh") OVER seven AS "MWh 7-day Moving Maximum",
FROM "Generation History"
WINDOW seven AS (
    PARTITION BY "Plant"
    ORDER BY "Date" ASC
    RANGE BETWEEN INTERVAL 3 DAYS PRECEDING
              AND INTERVAL 3 DAYS FOLLOWING)
ORDER BY 1, 2;
```

Constraints

In SQL, constraints can be specified for tables. Constraints enforce certain properties over data that is inserted into a table. Constraints can be specified along with the schema of the table as part of the CREATE TABLE statement. In certain cases, constraints can also be added to a table using the ALTER TABLE statement, but this is not currently supported for all constraints.

> **Warning.** Constraints have a strong impact on performance: they slow down loading and updates but speed up certain queries. Please consult the Performance Guide for details.

Syntax

Check Constraint

Check constraints allow you to specify an arbitrary Boolean expression. Any columns that *do not* satisfy this expression violate the constraint. For example, we could enforce that the name column does not contain spaces using the following CHECK constraint.

```
CREATE TABLE students (name VARCHAR CHECK (NOT contains(name, ' ')));
INSERT INTO students VALUES ('this name contains spaces');
```

```
Constraint Error:
CHECK constraint failed on table students with expression CHECK((NOT contains("name", ' ')))
```

Not Null Constraint

A not-null constraint specifies that the column cannot contain any NULL values. By default, all columns in tables are nullable. Adding NOT NULL to a column definition enforces that a column cannot contain NULL values.

```
CREATE TABLE students (name VARCHAR NOT NULL);
INSERT INTO students VALUES (NULL);
```

```
Constraint Error:
NOT NULL constraint failed: students.name
```

Primary Key and Unique Constraint

Primary key or unique constraints define a column, or set of columns, that are a unique identifier for a row in the table. The constraint enforces that the specified columns are *unique* within a table, i.e., that at most one row contains the given values for the set of columns.

```
CREATE TABLE students (id INTEGER PRIMARY KEY, name VARCHAR);
INSERT INTO students VALUES (1, 'Student 1');
INSERT INTO students VALUES (1, 'Student 2');
```

```
Constraint Error:
Duplicate key "id: 1" violates primary key constraint
```

```
CREATE TABLE students (id INTEGER, name VARCHAR, PRIMARY KEY (id, name));
INSERT INTO students VALUES (1, 'Student 1');
INSERT INTO students VALUES (1, 'Student 2');
INSERT INTO students VALUES (1, 'Student 1');
```

```
Constraint Error:
Duplicate key "id: 1, name: Student 1" violates primary key constraint
```

To enforce this property efficiently, an ART index is automatically created for every primary key or unique constraint that is defined in the table.

Primary key constraints and unique constraints are identical except for two points:

- A table can only have one primary key constraint defined, but many unique constraints
- A primary key constraint also enforces the keys to not be `NULL`.

```
CREATE TABLE students (id INTEGER PRIMARY KEY, name VARCHAR, email VARCHAR UNIQUE);
INSERT INTO students VALUES (1, 'Student 1', 'student1@uni.com');
INSERT INTO students VALUES (2, 'Student 2', 'student1@uni.com');
```

```
Constraint Error:
Duplicate key "email: student1@uni.com" violates unique constraint.
```

```
INSERT INTO students (id, name) VALUES (3, 'Student 3');
INSERT INTO students (name, email) VALUES ('Student 3', 'student3@uni.com');
```

```
Constraint Error:
NOT NULL constraint failed: students.id
```

> **Warning.** Indexes have certain limitations that might result in constraints being evaluated too eagerly, leading to constraint errors such as `violates primary key constraint` and `violates unique constraint`. See the Indexes page for more details.

You can also define a uniqueness constraint on multiple columns:

```
CREATE TABLE integers (i INTEGER, j INTEGER, k INTEGER, UNIQUE (i, j));
INSERT INTO integers VALUES (1, 2, 3);
INSERT INTO integers VALUES (1, 4, 5);
INSERT INTO integers VALUES (1, 2, 5);
```

```
Constraint Error:
Duplicate key "i: 1, j: 2" violates unique constraint.
```

Foreign Keys

Foreign keys define a column, or set of columns, that refer to a primary key or unique constraint from *another* table. The constraint enforces that the key exists in the other table.

```
CREATE TABLE students (id INTEGER PRIMARY KEY, name VARCHAR);
CREATE TABLE subjects (id INTEGER PRIMARY KEY, name VARCHAR);
CREATE TABLE exams (
    exam_id INTEGER PRIMARY KEY,
    subject_id INTEGER REFERENCES subjects(id),
    student_id INTEGER REFERENCES students(id),
    grade INTEGER
);
INSERT INTO students VALUES (1, 'Student 1');
INSERT INTO subjects VALUES (1, 'CS 101');
INSERT INTO exams VALUES (1, 1, 1, 10);
INSERT INTO exams VALUES (2, 1, 2, 10);
```

```
Constraint Error:
Violates foreign key constraint because key "id: 2" does not exist in the referenced table
```

To enforce this property efficiently, an ART index is automatically created for every foreign key constraint that is defined in the table.

> **Warning.** Indexes have certain limitations that might result in constraints being evaluated too eagerly, leading to constraint errors such as `violates primary key constraint` and `violates unique constraint`. See the indexes section for more details.

Indexes

Index Types

DuckDB has two built-in index types. Indexes can also be defined via extensions.

Min-Max Index (Zonemap)

A min-max index (also known as zonemap or block range index) is *automatically created* for columns of all general-purpose data types.

Adaptive Radix Tree (ART)

An Adaptive Radix Tree (ART) is mainly used to ensure primary key constraints and to speed up point and very highly selective (i.e., < 0.1%) queries. ART indexes can be created manually using the `CREATE INDEX` clause and they are automatically created for columns with a `UNIQUE` or `PRIMARY KEY` constraint.

> **Warning.** ART indexes must currently be able to fit in memory during index creation. Avoid creating ART indexes if the index does not fit in memory during index creation.

Indexes Defined by Extensions

DuckDB supports R-trees for spatial indexing via the `spatial` extension.

Persistence

Both min-max indexes and ART indexes are persisted on disk.

`CREATE INDEX` and `DROP INDEX` Statements

To create an ART index, use the `CREATE INDEX` statement. To drop an ART index, use the `DROP INDEX` statement.

Limitations of ART Indexes

ART indexes create a secondary copy of the data in a second location. Maintaining that second copy complicates processing. Thus, certain limitations currently apply when it comes to modifying data that is also stored in secondary indexes.

> As expected, indexes have a strong effect on performance, slowing down loading and updates, but speeding up certain queries. Please consult the Performance Guide for details.

Constraint Checking in UPDATE Statements

UPDATE statements on indexed columns and columns that cannot be updated in place are transformed into a DELETE of the original row followed by an INSERT of the updated row. This rewrite has performance implications, particularly for wide tables, as entire rows are rewritten instead of only the affected columns.

Additionally, it causes the following constraint-checking limitation of UPDATE statements. The same limitation exists in other DBMSs, like PostgreSQL.

In the example below, note how the number of rows exceeds DuckDB's standard vector size, which is 2048 by default. The UPDATE statement is rewritten into a DELETE, followed by an INSERT. This rewrite happens per chunk of data (2048 rows) moving through DuckDB's processing pipeline. When updating `i = 2047` to `i = 2048`, we do not yet know that 2048 becomes 2049, and so forth. That is because we have not yet seen that chunk. Thus, we throw a constraint violation.

```
CREATE TABLE my_table (i INTEGER PRIMARY KEY);
INSERT INTO my_table SELECT range FROM range(3_000);
UPDATE my_table SET i = i + 1;
```

```
Constraint Error:
Duplicate key "i: 2048" violates primary key constraint.
```

A workaround is to split the UPDATE into a `DELETE ... RETURNING ...` followed by an INSERT, with some additional logic to (temporarily) store the result of the DELETE. All statements should be run inside a transaction via BEGIN, and eventually COMMIT.

Here's an example of how that could look like in the command line client.

```
CREATE TABLE my_table (i INTEGER PRIMARY KEY);
INSERT INTO my_table SELECT range FROM range(3_000);

BEGIN;
CREATE TEMP TABLE tmp AS SELECT i FROM my_table;
DELETE FROM my_table;
INSERT INTO my_table SELECT i FROM tmp;
DROP TABLE tmp;
COMMIT;
```

In other clients, you might be able to fetch the result of `DELETE ... RETURNING ...`. Then, you can use that result in a subsequent `INSERT ...` statement, or potentially make use of DuckDB's `Appender` (if available in the client).

Over-Eager Constraint Checking in Foreign Keys

This limitation occurs if you meet the following conditions:

- A table has a `FOREIGN KEY` constraint.
- There is an UPDATE on a composite payload column (e.g., a LIST or a STRUCT), the corresponding `PRIMARY KEY` table, which DuckDB rewrites into a DELETE followed by an INSERT.
- The to-be-deleted row exists in the foreign key table.

If these hold, you'll encounter an unexpected constraint violation:

```
CREATE TABLE pk_table (id INTEGER PRIMARY KEY, payload VARCHAR[]);
INSERT INTO pk_table VALUES (1, ['hello']);
CREATE TABLE fk_table (id INTEGER REFERENCES pk_table(id));
INSERT INTO fk_table VALUES (1);
UPDATE pk_table SET payload = ['world'] WHERE id = 1;
```

```
Constraint Error:
Violates foreign key constraint because key "id: 1" is still referenced by a foreign key in a different
table. If this is an unexpected constraint violation, please refer to our foreign key limitations in the
documentation
```

The reason for this is that DuckDB does not yet support "looking ahead". During the INSERT, it is unaware it will reinsert the foreign key value as part of the UPDATE rewrite.

Meta Queries

Information Schema

The views in the `information_schema` are SQL-standard views that describe the catalog entries of the database. These views can be filtered to obtain information about a specific column or table. DuckDB's implementation is based on PostgreSQL's information schema.

Tables

`character_sets`: Character Sets

Column	Description	Type	Example
`character_set_catalog`	Currently not implemented – always `NULL`.	`VARCHAR`	`NULL`
`character_set_schema`	Currently not implemented – always `NULL`.	`VARCHAR`	`NULL`
`character_set_name`	Name of the character set, currently implemented as showing the name of the database encoding.	`VARCHAR`	`'UTF8'`
`character_repertoire`	Character repertoire, showing UCS if the encoding is `UTF8`, else just the encoding name.	`VARCHAR`	`'UCS'`
`form_of_use`	Character encoding form, same as the database encoding.	`VARCHAR`	`'UTF8'`
`default_collate_catalog`	Name of the database containing the default collation (always the current database).	`VARCHAR`	`'my_db'`
`default_collate_schema`	Name of the schema containing the default collation.	`VARCHAR`	`'pg_catalog'`
`default_collate_name`	Name of the default collation.	`VARCHAR`	`'ucs_basic'`

`columns`: Columns

The view that describes the catalog information for columns is `information_schema.columns`. It lists the columns present in the database and has the following layout:

Column	Description	Type	Example
`table_catalog`	Name of the database containing the table (always the current database).	`VARCHAR`	`'my_db'`
`table_schema`	Name of the schema containing the table.	`VARCHAR`	`'main'`

Column	Description	Type	Example
`table_name`	Name of the table.	`VARCHAR`	`'widgets'`
`column_name`	Name of the column.	`VARCHAR`	`'price'`
`ordinal_position`	Ordinal position of the column within the table (count starts at 1).	`INTEGER`	`5`
`column_default`	Default expression of the column.	`VARCHAR`	`1.99`
`is_nullable`	`YES` if the column is possibly nullable, `NO` if it is known not nullable.	`VARCHAR`	`'YES'`
`data_type`	Data type of the column.	`VARCHAR`	`'DECIMAL(18, 2)'`
`character_maximum_length`	If `data_type` identifies a character or bit string type, the declared maximum length; `NULL` for all other data types or if no maximum length was declared.	`INTEGER`	`255`
`character_octet_length`	If `data_type` identifies a character type, the maximum possible length in octets (bytes) of a datum; `NULL` for all other data types. The maximum octet length depends on the declared character maximum length (see above) and the character encoding.	`INTEGER`	`1073741824`
`numeric_precision`	If `data_type` identifies a numeric type, this column contains the (declared or implicit) precision of the type for this column. The precision indicates the number of significant digits. For all other data types, this column is `NULL`.	`INTEGER`	`18`
`numeric_scale`	If `data_type` identifies a numeric type, this column contains the (declared or implicit) scale of the type for this column. The scale indicates the number of digits after the decimal point. For all other data types, this column is `NULL`.	`INTEGER`	`2`
`datetime_precision`	If `data_type` identifies a date, time, timestamp, or interval type, this column contains the (declared or implicit) fractional seconds precision of the type for this column, that is, the number of decimal digits maintained following the decimal point in the seconds value. No fractional seconds are currently supported in DuckDB. For all other data types, this column is `NULL`.	`INTEGER`	`0`

`constraint_column_usage`: Constraint Column Usage

This view describes all columns in the current database that are used by some constraint. For a check constraint, this view identifies the columns that are used in the check expression. For a not-null constraint, this view identifies the column that the constraint is defined on. For a foreign key constraint, this view identifies the columns that the foreign key references. For a unique or primary key constraint, this view identifies the constrained columns.

Column	Description	Type	Example
`table_catalog`	Name of the database that contains the table that contains the column that is used by some constraint (always the current database)	`VARCHAR`	`'my_db'`
`table_schema`	Name of the schema that contains the table that contains the column that is used by some constraint	`VARCHAR`	`'main'`
`table_name`	Name of the table that contains the column that is used by some constraint	`VARCHAR`	`'widgets'`
`column_name`	Name of the column that is used by some constraint	`VARCHAR`	`'price'`
`constraint_catalog`	Name of the database that contains the constraint (always the current database)	`VARCHAR`	`'my_db'`
`constraint_schema`	Name of the schema that contains the constraint	`VARCHAR`	`'main'`
`constraint_name`	Name of the constraint	`VARCHAR`	`'exam_id_students_id_fkey'`

`key_column_usage`: Key Column Usage

Column	Description	Type	Example
`constraint_catalog`	Name of the database that contains the constraint (always the current database).	`VARCHAR`	`'my_db'`
`constraint_schema`	Name of the schema that contains the constraint.	`VARCHAR`	`'main'`
`constraint_name`	Name of the constraint.	`VARCHAR`	`'exams_exam_id_fkey'`
`table_catalog`	Name of the database that contains the table that contains the column that is restricted by this constraint (always the current database).	`VARCHAR`	`'my_db'`
`table_schema`	Name of the schema that contains the table that contains the column that is restricted by this constraint.	`VARCHAR`	`'main'`
`table_name`	Name of the table that contains the column that is restricted by this constraint.	`VARCHAR`	`'exams'`
`column_name`	Name of the column that is restricted by this constraint.	`VARCHAR`	`'exam_id'`
`ordinal_position`	Ordinal position of the column within the constraint key (count starts at 1).	`INTEGER`	`1`
`position_in_unique_constraint`	For a foreign-key constraint, ordinal position of the referenced column within its unique constraint (count starts at 1); otherwise `NULL`.	`INTEGER`	`1`

`referential_constraints`: Referential Constraints

Column	Description	Type	Example
`constraint_catalog`	Name of the database containing the constraint (always the current database).	`VARCHAR`	`'my_db'`
`constraint_schema`	Name of the schema containing the constraint.	`VARCHAR`	`main`
`constraint_name`	Name of the constraint.	`VARCHAR`	`exam_id_students_id_fkey`
`unique_constraint_catalog`	Name of the database that contains the unique or primary key constraint that the foreign key constraint references.	`VARCHAR`	`'my_db'`
`unique_constraint_schema`	Name of the schema that contains the unique or primary key constraint that the foreign key constraint references.	`VARCHAR`	`'main'`
`unique_constraint_name`	Name of the unique or primary key constraint that the foreign key constraint references.	`VARCHAR`	`'students_id_pkey'`
`match_option`	Match option of the foreign key constraint. Always `NONE`.	`VARCHAR`	`NONE`
`update_rule`	Update rule of the foreign key constraint. Always `NO ACTION`.	`VARCHAR`	`NO ACTION`
`delete_rule`	Delete rule of the foreign key constraint. Always `NO ACTION`.	`VARCHAR`	`NO ACTION`

`schemata`: Database, Catalog and Schema

The top level catalog view is `information_schema.schemata`. It lists the catalogs and the schemas present in the database and has the following layout:

Column	Description	Type	Example
`catalog_name`	Name of the database that the schema is contained in.	`VARCHAR`	`'my_db'`
`schema_name`	Name of the schema.	`VARCHAR`	`'main'`
`schema_owner`	Name of the owner of the schema. Not yet implemented.	`VARCHAR`	`'duckdb'`
`default_character_set_catalog`	Applies to a feature not available in DuckDB.	`VARCHAR`	`NULL`
`default_character_set_schema`	Applies to a feature not available in DuckDB.	`VARCHAR`	`NULL`
`default_character_set_name`	Applies to a feature not available in DuckDB.	`VARCHAR`	`NULL`
`sql_path`	Applies to a feature not available in DuckDB.	`VARCHAR`	`NULL`

`tables`: Tables and Views

The view that describes the catalog information for tables and views is `information_schema.tables`. It lists the tables present in the database and has the following layout:

Column	Description	Type	Example
table_catalog	The catalog the table or view belongs to.	VARCHAR	'my_db'
table_schema	The schema the table or view belongs to.	VARCHAR	'main'
table_name	The name of the table or view.	VARCHAR	'widgets'
table_type	The type of table. One of: BASE TABLE, LOCAL TEMPORARY, VIEW.	VARCHAR	'BASE TABLE'
self_referencing_column_name	Applies to a feature not available in DuckDB.	VARCHAR	NULL
reference_generation	Applies to a feature not available in DuckDB.	VARCHAR	NULL
user_defined_type_catalog	If the table is a typed table, the name of the database that contains the underlying data type (always the current database), else NULL. Currently unimplemented.	VARCHAR	NULL
user_defined_type_schema	If the table is a typed table, the name of the schema that contains the underlying data type, else NULL. Currently unimplemented.	VARCHAR	NULL
user_defined_type_name	If the table is a typed table, the name of the underlying data type, else NULL. Currently unimplemented.	VARCHAR	NULL
is_insertable_into	YES if the table is insertable into, NO if not (Base tables are always insertable into, views not necessarily.)	VARCHAR	'YES'
is_typed	YES if the table is a typed table, NO if not.	VARCHAR	'NO'
commit_action	Not yet implemented.	VARCHAR	'NO'

table_constraints: Table Constraints

Column	Description	Type	Example
constraint_catalog	Name of the database that contains the constraint (always the current database).	VARCHAR	'my_db'
constraint_schema	Name of the schema that contains the constraint.	VARCHAR	'main'
constraint_name	Name of the constraint.	VARCHAR	'exams_exam_id_fkey'
table_catalog	Name of the database that contains the table (always the current database).	VARCHAR	'my_db'
table_schema	Name of the schema that contains the table.	VARCHAR	'main'
table_name	Name of the table.	VARCHAR	'exams'
constraint_type	Type of the constraint: CHECK, FOREIGN KEY, PRIMARY KEY, or UNIQUE.	VARCHAR	'FOREIGN KEY'
is_deferrable	YES if the constraint is deferrable, NO if not.	VARCHAR	'NO'
initially_deferred	YES if the constraint is deferrable and initially deferred, NO if not.	VARCHAR	'NO'
enforced	Always YES.	VARCHAR	'YES'

Column	Description	Type	Example
`nulls_distinct`	If the constraint is a unique constraint, then `YES` if the constraint treats `NULL`s as distinct or `NO` if it treats `NULL`s as not distinct, otherwise `NULL` for other types of constraints.	VARCHAR	`'YES'`

Catalog Functions

Several functions are also provided to see details about the catalogs and schemas that are configured in the database.

Function	Description	Example	Result
`current_catalog()`	Return the name of the currently active catalog. Default is memory.	`current_catalog()`	`'memory'`
`current_schema()`	Return the name of the currently active schema. Default is main.	`current_schema()`	`'main'`
`current_schemas(boolean)`	Return list of schemas. Pass a parameter of `true` to include implicit schemas.	`current_schemas(true)`	`['temp', 'main', 'pg_catalog']`

DuckDB_% Metadata Functions

DuckDB offers a collection of table functions that provide metadata about the current database. These functions reside in the `main` schema and their names are prefixed with `duckdb_`.

The resultset returned by a `duckdb_` table function may be used just like an ordinary table or view. For example, you can use a `duckdb_` function call in the `FROM` clause of a `SELECT` statement, and you may refer to the columns of its returned resultset elsewhere in the statement, for example in the `WHERE` clause.

Table functions are still functions, and you should write parentheses after the function name to call it to obtain its returned resultset:

```
SELECT * FROM duckdb_settings();
```

Alternatively, you may execute table functions also using the `CALL`-syntax:

```
CALL duckdb_settings();
```

In this case too, the parentheses are mandatory.

> For some of the `duckdb_%` functions, there is also an identically named view available, which also resides in the `main` schema. Typically, these views do a `SELECT` on the `duckdb_` table function with the same name, while filtering out those objects that are marked as internal. We mention it here, because if you accidentally omit the parentheses in your `duckdb_` table function call, you might still get a result, but from the identically named view.

Example:

The `duckdb_views()` *table function* returns all views, including those marked internal:

```
SELECT * FROM duckdb_views();
```

The `duckdb_views` *view* returns views that are not marked as internal:

```
SELECT * FROM duckdb_views;
```

duckdb_columns

The `duckdb_columns()` function provides metadata about the columns available in the DuckDB instance.

Column	Description	Type
`database_name`	The name of the database that contains the column object.	`VARCHAR`
`database_oid`	Internal identifier of the database that contains the column object.	`BIGINT`
`schema_name`	The SQL name of the schema that contains the table object that defines this column.	`VARCHAR`
`schema_oid`	Internal identifier of the schema object that contains the table of the column.	`BIGINT`
`table_name`	The SQL name of the table that defines the column.	`VARCHAR`
`table_oid`	Internal identifier (name) of the table object that defines the column.	`BIGINT`
`column_name`	The SQL name of the column.	`VARCHAR`
`column_index`	The unique position of the column within its table.	`INTEGER`
`comment`	A comment created by the `COMMENT ON` statement.	`VARCHAR`
`internal`	`true` if this column is built-in, `false` if it is user-defined.	`BOOLEAN`
`column_default`	The default value of the column (expressed in SQL)	`VARCHAR`
`is_nullable`	`true` if the column can hold `NULL` values; `false` if the column cannot hold `NULL`-values.	`BOOLEAN`
`data_type`	The name of the column data type.	`VARCHAR`
`data_type_id`	The internal identifier of the column data type.	`BIGINT`
`character_maximum_length`	Always `NULL`. DuckDB text types do not enforce a value length restriction based on a length type parameter.	`INTEGER`
`numeric_precision`	The number of units (in the base indicated by `numeric_precision_radix`) used for storing column values. For integral and approximate numeric types, this is the number of bits. For decimal types, this is the number of digit positions.	`INTEGER`
`numeric_precision_radix`	The number-base of the units in the `numeric_precision` column. For integral and approximate numeric types, this is `2`, indicating the precision is expressed as a number of bits. For the `decimal` type this is `10`, indicating the precision is expressed as a number of decimal positions.	`INTEGER`
`numeric_scale`	Applicable to `decimal` type. Indicates the maximum number of fractional digits (i.e., the number of digits that may appear after the decimal separator).	`INTEGER`

The `information_schema.columns` system view provides a more standardized way to obtain metadata about database columns, but the `duckdb_columns` function also returns metadata about DuckDB internal objects. (In fact, `information_schema.columns` is implemented as a query on top of `duckdb_columns()`)

duckdb_constraints

The `duckdb_constraints()` function provides metadata about the constraints available in the DuckDB instance.

Column	Description	Type
database_name	The name of the database that contains the constraint.	VARCHAR
database_oid	Internal identifier of the database that contains the constraint.	BIGINT
schema_name	The SQL name of the schema that contains the table on which the constraint is defined.	VARCHAR
schema_oid	Internal identifier of the schema object that contains the table on which the constraint is defined.	BIGINT
table_name	The SQL name of the table on which the constraint is defined.	VARCHAR
table_oid	Internal identifier (name) of the table object on which the constraint is defined.	BIGINT
constraint_index	Indicates the position of the constraint as it appears in its table definition.	BIGINT
constraint_type	Indicates the type of constraint. Applicable values are CHECK, FOREIGN KEY, PRIMARY KEY, NOT NULL, UNIQUE.	VARCHAR
constraint_text	The definition of the constraint expressed as a SQL-phrase. (Not necessarily a complete or syntactically valid DDL-statement.)	VARCHAR
expression	If constraint is a check constraint, the definition of the condition being checked, otherwise NULL.	VARCHAR
constraint_column_indexes	An array of table column indexes referring to the columns that appear in the constraint definition.	BIGINT[]
constraint_column_names	An array of table column names appearing in the constraint definition.	VARCHAR[]
constraint_name	The name of the constraint.	VARCHAR
referenced_table	The table referenced by the constraint.	VARCHAR
referenced_column_names	The column names referenced by the constraint.	VARCHAR[]

The information_schema.referential_constraints and information_schema.table_constraints system views provide a more standardized way to obtain metadata about constraints, but the duckdb_constraints function also returns metadata about DuckDB internal objects. (In fact, information_schema.referential_constraints and information_schema.table_constraints are implemented as a query on top of duckdb_constraints())

duckdb_coordinate_systems

The duckdb_coordinate_systems() function lists the available coordinate reference systems (CRS) for use with the GEOMETRY data type.

Column	Description	Type
database_name	The name of the database that stores the CRS definition.	VARCHAR
database_oid	Internal identifier of the database that stores the CRS definition.	BIGINT
schema_name	The SQL name of the schema that stores the CRS definition.	VARCHAR
schema_oid	Internal identifier of the schema that stores the CRS definition.	BIGINT
crs_oid	Unique internal identifier for the CRS.	BIGINT

Column	Description	Type
`crs_name`	A unique name that identifies the CRS. (Typically, this value is identical to the `auth_name` and `auth_code`, separated by a colon)	`VARCHAR`
`auth_name`	The name of the authorithy that defined the CRS.	`VARCHAR`
`auth_code`	The code that defined the CRS within its authority.	`VARCHAR`
`projjson`	The projjson encoding of the CRS.	`VARCHAR`
`wkt2_2019`	The Well-Known Text (WKT) representation of the CRS.	`VARCHAR`

This function lists both built-in CRSs as well as the ones that are installed by extensions (such as the `SPATIAL` extension.

`duckdb_databases`

The `duckdb_databases()` function lists the databases that are accessible from within the current DuckDB process. Apart from the database associated at startup, the list also includes databases that were attached later on to the DuckDB process.

Column	Description	Type
`database_name`	The name of the database, or the alias if the database was attached using an ALIAS-clause.	`VARCHAR`
`database_oid`	The internal identifier of the database.	`VARCHAR`
`path`	The file path associated with the database.	`VARCHAR`
`comment`	A comment created by the `COMMENT ON` statement.	`VARCHAR`
`tags`	A map of string key–value pairs.	`MAP(VARCHAR, VARCHAR)`
`internal`	`true` indicates a system or built-in database. `false` indicates a user-defined database.	`BOOLEAN`
`type`	The type indicates the type of RDBMS implemented by the attached database. For DuckDB databases, that value is `duckdb`.	`VARCHAR`
`readonly`	Denotes whether the database is read-only.	`BOOLEAN`
`options`	The options used in the ATTACH statement, as a map of option names to their string values.	`MAP(VARCHAR, VARCHAR)`

`duckdb_dependencies`

The `duckdb_dependencies()` function provides metadata about the dependencies available in the DuckDB instance.

Column	Description	Type
`classid`	Always 0	`BIGINT`
`objid`	The internal id of the object.	`BIGINT`
`objsubid`	Always 0	`INTEGER`
`refclassid`	Always 0	`BIGINT`
`refobjid`	The internal id of the dependent object.	`BIGINT`
`refobjsubid`	Always 0	`INTEGER`

Column	Description	Type
deptype	The type of dependency. Either regular (n) or automatic (a).	VARCHAR

duckdb_extensions

The duckdb_extensions() function provides metadata about the extensions available in the DuckDB instance.

Column	Description	Type
extension_name	The name of the extension.	VARCHAR
loaded	true if the extension is loaded, false if it's not loaded.	BOOLEAN
installed	true if the extension is installed, false if it's not installed.	BOOLEAN
install_path	(BUILT-IN) if the extension is built-in, otherwise, the filesystem path where the binary that implements the extension resides.	VARCHAR
description	Human readable text that describes the extension's functionality.	VARCHAR
aliases	List of alternative names for this extension.	VARCHAR[]
extension_version	The version of the extension (vX.Y.Z for stable versions and 6-character hash for unstable versions).	VARCHAR
install_mode	The installation mode that was used to install the extension: UNKNOWN, REPOSITORY, CUSTOM_PATH, STATICALLY_LINKED, NOT_INSTALLED, NULL.	VARCHAR
installed_from	Name of the repository the extension was installed from, e.g., community or core_nightly. The empty string denotes the core repository.	VARCHAR

duckdb_functions

The duckdb_functions() function provides metadata about the functions (including macros) available in the DuckDB instance.

Column	Description	Type
database_name	The name of the database that contains this function.	VARCHAR
database_oid	Internal identifier of the database containing the index.	BIGINT
schema_name	The SQL name of the schema where the function resides.	VARCHAR
function_name	The SQL name of the function.	VARCHAR
function_type	The function kind. Value is one of: table, scalar, aggregate, pragma, macro, table_macro	VARCHAR
description	Description of this function (always NULL)	VARCHAR
comment	A comment created by the COMMENT ON statement.	VARCHAR
tags	A map of string key–value pairs.	MAP(VARCHAR, VARCHAR)
return_type	The logical data type name of the returned value. Applicable for scalar and aggregate functions.	VARCHAR
parameters	If the function has parameters, the list of parameter names.	VARCHAR[]
parameter_types	If the function has parameters, a list of logical data type names corresponding to the parameter list.	VARCHAR[]

Column	Description	Type
varargs	The name of the data type in case the function has a variable number of arguments, or NULL if the function does not have a variable number of arguments.	VARCHAR
macro_definition	If this is a macro, the SQL expression that defines it.	VARCHAR
has_side_effects	false if this is a pure function. true if this function changes the database state (like sequence functions nextval() and curval()).	BOOLEAN
internal	true if the function is built-in (defined by DuckDB or an extension), false if it was defined using the CREATE MACRO statement.	BOOLEAN
function_oid	The internal identifier for this function.	BIGINT
examples	Examples of using the function. Used to generate the documentation.	VARCHAR[]
stability	The stability of the function (CONSISTENT, VOLATILE, CONSISTENT_WITHIN_QUERY or NULL)	VARCHAR

duckdb_indexes

The duckdb_indexes() function provides metadata about secondary indexes available in the DuckDB instance.

Column	Description	Type
database_name	The name of the database that contains this index.	VARCHAR
database_oid	Internal identifier of the database containing the index.	BIGINT
schema_name	The SQL name of the schema that contains the table with the secondary index.	VARCHAR
schema_oid	Internal identifier of the schema object.	BIGINT
index_name	The SQL name of this secondary index.	VARCHAR
index_oid	The object identifier of this index.	BIGINT
table_name	The name of the table with the index.	VARCHAR
table_oid	Internal identifier (name) of the table object.	BIGINT
comment	A comment created by the COMMENT ON statement.	VARCHAR
tags	A map of string key–value pairs.	MAP(VARCHAR, VARCHAR)
is_unique	true if the index was created with the UNIQUE modifier, false if it was not.	BOOLEAN
is_primary	Always false.	BOOLEAN
expressions	Always NULL.	VARCHAR
sql	The definition of the index, expressed as a CREATE INDEX SQL statement.	VARCHAR

Note that duckdb_indexes only provides metadata about secondary indexes, i.e., those indexes created by explicit CREATE INDEX statements. Primary keys, foreign keys, and UNIQUE constraints are maintained using indexes, but their details are included in the duckdb_constraints() function.

duckdb_keywords

The `duckdb_keywords()` function provides metadata about DuckDB's keywords and reserved words.

Column	Description	Type
`keyword_name`	The keyword.	`VARCHAR`
`keyword_category`	The category of the keyword: `reserved` (cannot be used as an identifier without quoting), `unreserved` (can be used as an identifier), `column_name` (usable as a column name but not as a type or function name), or `type_function` (usable as a type or function name but not as a column name). See Keywords and Identifiers.	`VARCHAR`

duckdb_log_contexts

The `duckdb_log_contexts()` function provides information on the contexts of DuckDB log entries.

Column	Description	Type
`context_id`	The identifier of the context. The `context_id` column in the `duckdb_logs` table is a foreign key that points to this column.	`UBIGINT`
`scope`	The scope of the context (`connection`, `database` or `file_opener`).	`VARCHAR`
`connection_id`	The identifier of the connection.	`UBIGINT`
`transaction_id`	The identifier of the transaction.	`UBIGINT`
`query_id`	The identifier of the query.	`UBIGINT`
`thread_id`	The identifier of the thread.	`UBIGINT`

duckdb_logs

The `duckdb_logs()` function returns a table of DuckDB log entries.

Column	Description	Type
`context_id`	The identifier of the context of the log entry. Foreign key to the `duckdb_log_contexts` table.	`UBIGINT`
`timestamp`	The timestamp of the log entry.	`TIMESTAMP`
`type`	The type of the log entry.	`VARCHAR`
`log_level`	The level of the log entry (`TRACE`, `DEBUG`, `INFO`, `WARN`, `ERROR` or `FATAL`).	`VARCHAR`
`message`	The message of the log entry.	`VARCHAR`

duckdb_memory

The `duckdb_memory()` function provides metadata about DuckDB's buffer manager.

Column	Description	Type
`tag`	The memory tag. It has one of the following values: `BASE_TABLE`, `HASH_TABLE`, `PARQUET_READER`, `CSV_READER`, `ORDER_BY`, `ART_INDEX`, `COLUMN_DATA`, `METADATA`, `OVERFLOW_STRINGS`, `IN_MEMORY_TABLE`, `ALLOCATOR`, `EXTENSION`.	`VARCHAR`
`memory_usage_bytes`	The memory used (in bytes).	`BIGINT`
`temporary_storage_bytes`	The disk storage used (in bytes).	`BIGINT`

`duckdb_optimizers`

The `duckdb_optimizers()` function provides metadata about the optimization rules (e.g., `expression_rewriter`, `filter_pushdown`) available in the DuckDB instance. These can be selectively turned off using `PRAGMA disabled_optimizers`.

Column	Description	Type
`name`	The name of the optimization rule.	`VARCHAR`

`duckdb_prepared_statements`

The `duckdb_prepared_statements()` function provides metadata about the prepared statements that exist in the current DuckDB session.

Column	Description	Type
`name`	The name of the prepared statement.	`VARCHAR`
`statement`	The SQL statement.	`VARCHAR`
`parameter_types`	The expected parameter types for the statement's parameters. Currently returns `UNKNOWN` for all parameters.	`VARCHAR[]`
`result_types`	The types of the columns in the table returned by the prepared statement.	`VARCHAR[]`

`duckdb_profiling_settings`

The `duckdb_profiling_settings()` macro returns the current profiling-related settings from `duckdb_settings()`.

Column	Description	Type
`name`	The name of the profiling setting.	`VARCHAR`
`value`	The current value of the setting.	`VARCHAR`
`description`	A description of the setting.	`VARCHAR`

duckdb_schemas

The `duckdb_schemas()` function provides metadata about the schemas available in the DuckDB instance.

Column	Description	Type
`oid`	Internal identifier of the schema object.	`BIGINT`
`database_name`	The name of the database that contains this schema.	`VARCHAR`
`database_oid`	Internal identifier of the database containing the schema.	`BIGINT`
`schema_name`	The SQL name of the schema.	`VARCHAR`
`comment`	A comment created by the `COMMENT ON` statement.	`VARCHAR`
`tags`	A map of string key–value pairs.	`MAP(VARCHAR, VARCHAR)`
`internal`	`true` if this is an internal (built-in) schema, `false` if this is a user-defined schema.	`BOOLEAN`
`sql`	Always `NULL`	`VARCHAR`

The `information_schema.schemata` system view provides a more standardized way to obtain metadata about database schemas.

duckdb_secret_types

The `duckdb_secret_types()` lists secret types that are supported in the current DuckDB session.

Column	Description	Type
`type`	The name of the secret type, e.g., `s3`.	`VARCHAR`
`default_provider`	The default secret provider, e.g., `config`.	`VARCHAR`
`extension`	The extension that registered the secret type, e.g., `aws`.	`VARCHAR`

duckdb_secrets

The `duckdb_secrets()` function provides metadata about the secrets available in the DuckDB instance.

Column	Description	Type
`name`	The name of the secret.	`VARCHAR`
`type`	The type of the secret, e.g., `S3`, `GCS`, `R2`, `AZURE`.	`VARCHAR`
`provider`	The provider of the secret.	`VARCHAR`
`persistent`	Denotes whether the secret is persistent.	`BOOLEAN`
`storage`	The backend for storing the secret.	`VARCHAR`
`scope`	The scope of the secret.	`VARCHAR[]`
`secret_string`	Returns the content of the secret as a string. Sensitive pieces of information, e.g., the access key, are redacted.	`VARCHAR`

duckdb_sequences

The `duckdb_sequences()` function provides metadata about the sequences available in the DuckDB instance.

Column	Description	Type
`database_name`	The name of the database that contains this sequence	`VARCHAR`
`database_oid`	Internal identifier of the database containing the sequence.	`BIGINT`
`schema_name`	The SQL name of the schema that contains the sequence object.	`VARCHAR`
`schema_oid`	Internal identifier of the schema object that contains the sequence object.	`BIGINT`
`sequence_name`	The SQL name that identifies the sequence within the schema.	`VARCHAR`
`sequence_oid`	The internal identifier of this sequence object.	`BIGINT`
`comment`	A comment created by the `COMMENT ON` statement.	`VARCHAR`
`tags`	A map of string key–value pairs.	`MAP(VARCHAR, VARCHAR)`
`temporary`	Whether this sequence is temporary. Temporary sequences are transient and only visible within the current connection.	`BOOLEAN`
`start_value`	The initial value of the sequence. This value will be returned when `nextval()` is called for the very first time on this sequence.	`BIGINT`
`min_value`	The minimum value of the sequence.	`BIGINT`
`max_value`	The maximum value of the sequence.	`BIGINT`
`increment_by`	The value that is added to the current value of the sequence to draw the next value from the sequence.	`BIGINT`
`cycle`	Whether the sequence should start over when drawing the next value would result in a value outside the range.	`BOOLEAN`
`last_value`	`NULL` if no value was ever drawn from the sequence using `nextval(...)`. `1` if a value was drawn.	`BIGINT`
`sql`	The definition of this object, expressed as SQL DDL-statement.	`VARCHAR`

Attributes like `temporary`, `start_value` etc. correspond to the various options available in the `CREATE SEQUENCE` statement and are documented there in full. Note that the attributes will always be filled out in the `duckdb_sequences` resultset, even if they were not explicitly specified in the `CREATE SEQUENCE` statement.

> 1. The column name `last_value` suggests that it contains the last value that was drawn from the sequence, but that is not the case. It's either `NULL` if a value was never drawn from the sequence, or `1` (when there was a value drawn, ever, from the sequence).
> 2. If the sequence cycles, then the sequence will start over from the boundary of its range, not necessarily from the value specified as start value.

duckdb_settings

The `duckdb_settings()` function provides metadata about the settings available in the DuckDB instance.

Column	Description	Type
`name`	Name of the setting.	`VARCHAR`

Column	Description	Type
`value`	Current value of the setting.	`VARCHAR`
`description`	A description of the setting.	`VARCHAR`
`input_type`	The logical data type of the setting's value.	`VARCHAR`
`scope`	The scope of the setting (`LOCAL` or `GLOBAL`).	`VARCHAR`

The various settings are described in the configuration page.

`duckdb_tables`

The `duckdb_tables()` function provides metadata about the base tables available in the DuckDB instance.

Column	Description	Type
`database_name`	The name of the database that contains this table	`VARCHAR`
`database_oid`	Internal identifier of the database containing the table.	`BIGINT`
`schema_name`	The SQL name of the schema that contains the base table.	`VARCHAR`
`schema_oid`	Internal identifier of the schema object that contains the base table.	`BIGINT`
`table_name`	The SQL name of the base table.	`VARCHAR`
`table_oid`	Internal identifier of the base table object.	`BIGINT`
`comment`	A comment created by the `COMMENT ON` statement.	`VARCHAR`
`tags`	A map of string key–value pairs.	`MAP(VARCHAR, VARCHAR)`
`internal`	`false` if this is a user-defined table.	`BOOLEAN`
`temporary`	Whether this is a temporary table. Temporary tables are not persisted and only visible within the current connection.	`BOOLEAN`
`has_primary_key`	`true` if this table object defines a `PRIMARY KEY`.	`BOOLEAN`
`estimated_size`	The estimated number of rows in the table.	`BIGINT`
`column_count`	The number of columns defined by this object.	`BIGINT`
`index_count`	The number of indexes associated with this table. This number includes all secondary indexes, as well as internal indexes generated to maintain `PRIMARY KEY` and/or `UNIQUE` constraints.	`BIGINT`
`check_constraint_count`	The number of check constraints active on columns within the table.	`BIGINT`
`sql`	The definition of this object, expressed as SQL `CREATE TABLE`-statement.	`VARCHAR`

The `information_schema.tables` system view provides a more standardized way to obtain metadata about database tables that also includes views. But the resultset returned by `duckdb_tables` contains a few columns that are not included in `information_schema.tables`.

duckdb_temporary_files

The `duckdb_temporary_files()` function provides metadata about the temporary files DuckDB has written to disk, to offload data from memory. This function mostly exists for debugging and testing purposes.

Column	Description	Type
`path`	The name of the temporary file.	`VARCHAR`
`size`	The size in bytes of the temporary file.	`BIGINT`

duckdb_types

The `duckdb_types()` function provides metadata about the data types available in the DuckDB instance.

Column	Description	Type
`database_name`	The name of the database that contains this schema.	`VARCHAR`
`database_oid`	Internal identifier of the database that contains the data type.	`BIGINT`
`schema_name`	The SQL name of the schema containing the type definition. Always `main`.	`VARCHAR`
`schema_oid`	Internal identifier of the schema object.	`BIGINT`
`type_name`	The name or alias of this data type.	`VARCHAR`
`type_oid`	The internal identifier of the data type object. If `NULL`, then this is an alias of the type (as identified by the value in the `logical_type` column).	`BIGINT`
`type_size`	The number of bytes required to represent a value of this type in memory.	`BIGINT`
`logical_type`	The 'canonical' name of this data type. The same `logical_type` may be referenced by several types having different `type_names`.	`VARCHAR`
`type_category`	The category to which this type belongs. Data types within the same category generally expose similar behavior when values of this type are used in expressions. For example, the `NUMERIC` type_category includes integers, decimals and floating point numbers.	`VARCHAR`
`comment`	A comment created by the `COMMENT ON` statement.	`VARCHAR`
`tags`	A map of string key–value pairs.	`MAP(VARCHAR, VARCHAR)`
`internal`	Whether this is an internal (built-in) or a user object.	`BOOLEAN`
`labels`	Labels for categorizing types. Used for generating the documentation.	`VARCHAR[]`

duckdb_variables

The `duckdb_variables()` function provides metadata about the variables available in the DuckDB instance.

Column	Description	Type
name	The name of the variable, e.g., x.	VARCHAR
value	The value of the variable, e.g., 12.	VARCHAR
type	The type of the variable, e.g., INTEGER.	VARCHAR

duckdb_views

The duckdb_views() function provides metadata about the views available in the DuckDB instance.

Column	Description	Type
database_name	The name of the database that contains this view.	VARCHAR
database_oid	Internal identifier of the database that contains this view.	BIGINT
schema_name	The SQL name of the schema where the view resides.	VARCHAR
schema_oid	Internal identifier of the schema object that contains the view.	BIGINT
view_name	The SQL name of the view object.	VARCHAR
view_oid	The internal identifier of this view object.	BIGINT
comment	A comment created by the COMMENT ON statement.	VARCHAR
tags	A map of string key–value pairs.	MAP(VARCHAR, VARCHAR)
internal	true if this is an internal (built-in) view, false if this is a user-defined view.	BOOLEAN
temporary	true if this is a temporary view. Temporary views are not persistent and are only visible within the current connection.	BOOLEAN
column_count	The number of columns defined by this view object.	BIGINT
sql	The definition of this object, expressed as SQL DDL-statement.	VARCHAR

The information_schema.tables system view provides a more standardized way to obtain metadata about database views that also includes base tables. But the resultset returned by duckdb_views contains also definitions of internal view objects as well as a few columns that are not included in information_schema.tables.

DuckDB's SQL Dialect

Overview

DuckDB's SQL dialect is based on PostgreSQL. DuckDB tries to closely match PostgreSQL's semantics, however, some use cases require slightly different behavior. For example, interchangeability with data frame libraries necessitates order preservation of inserts to be supported by default. These differences are documented in the pages below.

Indexing

DuckDB uses 1-based indexing except for JSON objects, which use 0-based indexing.

Examples

The index origin is 1 for strings, lists, etc.

```
SELECT list[1] AS element
FROM (SELECT ['first', 'second', 'third'] AS list);
```

```
┌─────────┐
│ element │
│ varchar │
├─────────┤
│ first   │
└─────────┘
```

The index origin is 0 for JSON objects.

```
SELECT json[1] AS element
FROM (SELECT '["first", "second", "third"]'::JSON AS json);
```

```
┌─────────┐
│ element │
│  json   │
├─────────┤
│ "second"│
└─────────┘
```

Friendly SQL

DuckDB offers several advanced SQL features and syntactic sugar to make SQL queries more concise. We refer to these colloquially as "friendly SQL".

> Several of these features were first introduced by DuckDB, while some are inspired by other systems. Many of the features originally introduced by DuckDB (e.g., `GROUP BY ALL`) have been since adapted by other systems.

> **Tip.** We have a Friendly SQL 2026 Calendar with a short explanation, an example, and an abstract illustration for 12 friendly SQL features.

Clauses

- Creating tables and inserting data:
  - `CREATE OR REPLACE TABLE`: avoid `DROP TABLE IF EXISTS` statements in scripts.
  - `CREATE TABLE ... AS SELECT` (CTAS): create a new table from the output of a table without manually defining a schema.
  - `INSERT INTO ... BY NAME`: this variant of the `INSERT` statement allows using column names instead of positions.
  - `INSERT OR IGNORE INTO ...`: insert the rows that do not result in a conflict due to `UNIQUE` or `PRIMARY KEY` constraints.
  - `INSERT OR REPLACE INTO ...`: insert the rows that do not result in a conflict due to `UNIQUE` or `PRIMARY KEY` constraints. For those that result in a conflict, replace the columns of the existing row to the new values of the to-be-inserted row.
- Describing tables and computing statistics:
  - `DESCRIBE`: provides a succinct summary of the schema of a table or query.
  - `SUMMARIZE`: returns summary statistics for a table or query.
- Making SQL clauses more compact and readable:
  - FROM-first syntax with an optional `SELECT` clause: DuckDB allows queries in the form of `FROM tbl` which selects all columns (performing a `SELECT *` statement).
  - `GROUP BY ALL`: omit the group-by columns by inferring them from the list of attributes in the `SELECT` clause.
  - `ORDER BY ALL`: shorthand to order on all columns (e.g., to ensure deterministic results).
  - `SELECT * EXCLUDE`: the `EXCLUDE` option allows excluding specific columns from the `*` expression.
  - `SELECT * REPLACE`: the `REPLACE` option allows replacing specific columns with different expressions in a `*` expression.
  - `UNION BY NAME`: perform the `UNION` operation along the names of columns (instead of relying on positions).
  - Prefix aliases in the `SELECT` and `FROM` clauses: write `x: 42` instead of `42 AS x` for improved readability.
  - Specifying a percentage of the table size for the `LIMIT` clause: write `LIMIT 10%` to return 10% of the query results.
- Transforming tables:
  - `PIVOT` to turn long tables to wide tables.
  - `UNPIVOT` to turn wide tables to long tables.
- Defining SQL-level variables:
  - `SET VARIABLE`
  - `RESET VARIABLE`

Query Features

- Column aliases in `WHERE`, `GROUP BY`, and `HAVING`. (Note that column aliases cannot be used in the `ON` clause of `JOIN` clauses.)
- `COLUMNS()` expression can be used to execute the same expression on multiple columns:
  - with regular expressions
  - with `EXCLUDE` and `REPLACE`
  - with lambda functions
- Reusable column aliases (also known as "lateral column aliases"), e.g.: `SELECT i + 1 AS j, j + 2 AS k FROM range(0, 3) t(i)`
- Advanced aggregation features for analytical (OLAP) queries:
  - `FILTER` clause
  - `GROUPING SETS`, `GROUP BY CUBE`, `GROUP BY ROLLUP` clauses
- `count()` shorthand for `count(*)`

- `IN` operator for lists and maps
- Specifying column names for common table expressions (`WITH`)
- Specifying column names in the `JOIN` clause
- Using `VALUES` in the `JOIN` clause
- Using `VALUES` in the anchor part of common table expressions
- `SWITCH` statements as syntactic sugar for the `CASE` expression

Literals and Identifiers

- Case-insensitivity while maintaining case of entities in the catalog
- Deduplicating identifiers
- Underscores as digit separators in numeric literals

Data Types

- `MAP` data type
- `UNION` data type

Data Import

- Auto-detecting the headers and schema of CSV files
- Directly querying CSV files and Parquet files
- Replacement scans:
  - You can load from files using the syntax `FROM 'my.csv'`, `FROM 'my.csv.gz'`, `FROM 'my.parquet'`, etc.
  - In Python, you can access Pandas data frames using `FROM df`.
- Filename expansion (globbing), e.g.: `FROM 'my-data/part-*.parquet'`

Functions and Expressions

- Dot operator for function chaining: `SELECT ('hello').upper()`
- String formatters: the `format()` function with the `fmt` syntax and the `printf() function`
- List comprehensions
- List slicing and indexing from the back (`[-1]`)
- String slicing
- `STRUCT.*` notation
- Creating `LIST` using square brackets
- Simple `LIST` and `STRUCT` creation
- Updating the schema of `STRUCT`s

Join Types

- `ASOF` joins
- `LATERAL` joins
- `POSITIONAL` joins

Trailing Commas

DuckDB allows trailing commas, both when listing entities (e.g., column and table names) and when constructing `LIST` items. For example, the following query works:

```
SELECT
    42 AS x,
    ['a', 'b', 'c',] AS y,
    'hello world' AS z,
;
```

"Top-N in Group" Queries

Computing the "top-N rows in a group" ordered by some criteria is a common task in SQL that unfortunately often requires a complex query involving window functions and/or subqueries.

To aid in this, DuckDB provides the aggregate functions `max(arg, n)`, `min(arg, n)`, `arg_max(arg, val, n)`, `arg_min(arg, val, n)`, `max_by(arg, val, n)` and `min_by(arg, val, n)` to efficiently return the "top" n rows in a group based on a specific column in either ascending or descending order.

For example, let's use the following table:

```
SELECT * FROM t1;
```

grp varchar	val int32
a	2
a	1
b	5
b	4
a	3
b	6

We want to get a list of the top-3 `val` values in each group `grp`. The conventional way to do this is to use a window function in a subquery:

```
SELECT array_agg(rs.val), rs.grp
FROM
    (SELECT val, grp, row_number() OVER (PARTITION BY grp ORDER BY val DESC) AS rid
    FROM t1 ORDER BY val DESC) AS rs
WHERE rid < 4
GROUP BY rs.grp;
```

array_agg(rs.val) int32[]	grp varchar
[3, 2, 1]	a
[6, 5, 4]	b

But in DuckDB, we can do this much more concisely (and efficiently!):

```
SELECT max(val, 3) FROM t1 GROUP BY grp;
```

max(val, 3) int32[]

```
[3, 2, 1]
[6, 5, 4]
```

Keywords and Identifiers

Identifiers

Similarly to other SQL dialects and programming languages, identifiers in DuckDB's SQL are subject to several rules.

- Unquoted identifiers need to conform to a number of rules:
  - They must not be a reserved keyword (see `duckdb_keywords()`), e.g., `SELECT 123 AS SELECT` will fail.
  - They must not start with a number or special character, e.g., `SELECT 123 AS 1col` is invalid.
  - They cannot contain whitespaces (including tabs and newline characters).
- Identifiers can be quoted using double-quote characters (`"`). Quoted identifiers can use any keyword, whitespace or special character, e.g., `"SELECT"` and `" § 🦢 ¶ "` are valid identifiers.
- Double quotes can be escaped by repeating the quote character, e.g., to create an identifier named `IDENTIFIER "X"`, use `"IDENTIFIER ""X"""`.

Deduplicating Identifiers

In some cases, duplicate identifiers can occur, e.g., column names may conflict when unnesting a nested data structure. In these cases, DuckDB automatically deduplicates column names by renaming them according to the following rules:

- For a column named <name>{:.language-sql .highlight}, the first instance is not renamed.
- Subsequent instances are renamed to <name>_<count>{:.language-sql .highlight}, where <count>{:.language-sql .highlight} starts at 1.

For example:

```
SELECT *
FROM (SELECT unnest({'a': 42, 'b': {'a': 88, 'b': 99}}, recursive := true));
```

a	a_1	b
42	88	99

Database Names

Database names are subject to the rules for identifiers.

Additionally, it is best practice to avoid DuckDB's two internal database schema names, `system` and `temp`. By default, persistent databases are named after their filename without the extension. Therefore, the filenames `system.db` and `temp.db` (as well as `system.duckdb` and `temp.duckdb`) result in the database names `system` and `temp`, respectively. If you need to attach to a database that has one of these names, use an alias, e.g.:

```
ATTACH 'temp.db' AS temp2;
USE temp2;
```

Rules for Case-Sensitivity

Keywords and Function Names

SQL keywords and function names are case-insensitive in DuckDB.

For example, the following two queries are equivalent:

```
select COS(Pi()) as CosineOfPi;
SELECT cos(pi()) AS CosineOfPi;
```

CosineOfPi
-1.0

Case-Sensitivity of Identifiers

Identifiers in DuckDB are always case-insensitive, similarly to PostgreSQL. However, unlike PostgreSQL (and some other major SQL implementations), DuckDB also treats quoted identifiers as case-insensitive.

Comparison of identifiers: Case-insensitivity is implemented using an ASCII-based comparison: `col_A` and `col_a` are equal but `col_á` is not equal to them.

```
SELECT col_A FROM (SELECT 'x' AS col_a); -- succeeds
SELECT col_á FROM (SELECT 'x' AS col_a); -- fails
```

Preserving cases: While DuckDB treats identifiers in a case-insensitive manner, it preserves the cases of these identifiers. That is, each character's case (uppercase/lowercase) is maintained as originally specified by the user even if a query uses different cases when referring to the identifier. For example:

```
CREATE TABLE tbl AS SELECT cos(pi()) AS CosineOfPi;
SELECT cosineofpi FROM tbl;
```

CosineOfPi
-1.0

To change this behavior, set the `preserve_identifier_case` configuration option to `false`.

Case-Sensitivity of Keys in Nested Data Structures

The keys of MAPs are case-sensitive:

```
SELECT MAP(['key1'], [1]) = MAP(['KEY1'], [1]) AS equal;
```

```
false
```

The keys of UNIONs and STRUCTs are case-insensitive:

```
SELECT {'key1': 1} = {'KEY1': 1} AS equal;
```

```
true
```

```
SELECT union_value(key1 := 1) = union_value(KEY1 := 1) as equal;
```

```
true
```

Handling Conflicts In case of a conflict, when the same identifier is spelt with different cases, one will be selected randomly. For example:

```
CREATE TABLE t1 (idfield INTEGER, x INTEGER);
CREATE TABLE t2 (IdField INTEGER, y INTEGER);
INSERT INTO t1 VALUES (1, 123);
INSERT INTO t2 VALUES (1, 456);
SELECT * FROM t1 NATURAL JOIN t2;
```

idfield	x	y
1	123	456

Disabling Preserving Cases With the `preserve_identifier_case` configuration option set to `false`, all identifiers are turned into lowercase:

```
SET preserve_identifier_case = false;
CREATE TABLE tbl AS SELECT cos(pi()) AS CosineOfPi;
SELECT CosineOfPi FROM tbl;
```

cosineofpi
-1.0

Order Preservation

For many operations, DuckDB preserves the order of rows, similarly to data frame libraries such as Pandas.

Example

Take the following table for example:

```
CREATE TABLE tbl AS
    SELECT *
    FROM (VALUES (1, 'a'), (2, 'b'), (3, 'c')) t(x, y);

SELECT *
FROM tbl;
```

x	y
1	a
2	b
3	c

Let's take the following query that returns the rows where x is an odd number:

```
SELECT *
FROM tbl
WHERE x % 2 == 1;
```

x	y
1	a
3	c

Because the row `(1, 'a')` occurs before `(3, 'c')` in the original table, it is guaranteed to come before that row in this table too.

Clauses

The following clauses guarantee that the original row order is preserved:

- `COPY` (see Insertion Order)
- `FROM` with a single table
- `LIMIT`
- `OFFSET`
- `SELECT`
- `UNION ALL`
- `WHERE`
- Window functions with an empty `OVER` clause
- Common table expressions and table subqueries as long as they only contain the aforementioned components

> **Tip.** `row_number() OVER ()` allows turning the original row order into an explicit column that can be referenced in the operations that don't preserve row order by default. On materialized tables, the `rowid` pseudo-column can be used to the same effect.

The following operations **do not** guarantee that the row order is preserved:

- `FROM` with multiple tables and/or subqueries
- `JOIN`
- `UNION`
- `USING SAMPLE`
- Whole-table aggregation (the input order, that is, the order in which rows are fed into order-sensitive aggregate functions is not guaranteed unless explicitly specified in the aggregate function)
- `GROUP BY` (neither in- nor output order are guaranteed)
- `ORDER BY` (specifically, `ORDER BY` may not use a stable algorithm)
- Scalar subqueries

Insertion Order

By default, the following components preserve insertion order:

- CSV reader (`read_csv` function)
- JSON reader (`read_json` function)
- Parquet reader (`read_parquet` function)

Preservation of insertion order is controlled by the `preserve_insertion_order` configuration option. This setting is `true` by default, indicating that the order should be preserved. To change this setting, use:

```
SET preserve_insertion_order = false;
```

PostgreSQL Compatibility

DuckDB's SQL dialect closely follows the conventions of the PostgreSQL dialect. The few exceptions to this are listed on this page.

Floating-Point Arithmetic

DuckDB and PostgreSQL handle floating-point arithmetic differently for division by zero. DuckDB conforms to the IEEE Standard for Floating-Point Arithmetic (IEEE 754) for both division by zero and operations involving infinity values. PostgreSQL returns an error for division by zero but aligns with IEEE 754 for handling infinity values. To show the differences, run the following SQL queries:

```
SELECT 1.0 / 0.0 AS x;
SELECT 0.0 / 0.0 AS x;
SELECT -1.0 / 0.0 AS x;
SELECT 'Infinity'::FLOAT / 'Infinity'::FLOAT AS x;
SELECT 1.0 / 'Infinity'::FLOAT AS x;
SELECT 'Infinity'::FLOAT - 'Infinity'::FLOAT AS x;
SELECT 'Infinity'::FLOAT - 1.0 AS x;
```

Expression	PostgreSQL	DuckDB	IEEE 754
1.0 / 0.0	error	Infinity	Infinity
0.0 / 0.0	error	NaN	NaN
-1.0 / 0.0	error	-Infinity	-Infinity
'Infinity' / 'Infinity'	NaN	NaN	NaN
1.0 / 'Infinity'	0.0	0.0	0.0
'Infinity' - 'Infinity'	NaN	NaN	NaN
'Infinity' - 1.0	Infinity	Infinity	Infinity

Division on Integers

When computing division on integers, PostgreSQL performs integer division, while DuckDB performs float division:

```
SELECT 1 / 2 AS x;
```

PostgreSQL returns `0`, while DuckDB returns `0.5`.

To perform integer division in DuckDB, use the `//` operator:

```
SELECT 1 // 2 AS x;
```

This returns `0`.

`UNION` of Boolean and Integer Values

The following query fails in PostgreSQL but successfully completes in DuckDB:

```
SELECT true AS x
UNION
SELECT 2;
```

PostgreSQL returns an error:

```
ERROR:  UNION types boolean and integer cannot be matched
```

DuckDB performs an enforced cast, therefore, it completes the query and returns the following:

x
1
2

Implicit Casting on Equality Checks

DuckDB performs implicit casting on equality checks, e.g., converting strings to numeric and boolean values. Therefore, there are several instances, where PostgreSQL throws an error while DuckDB successfully computes the result:

Expression	PostgreSQL	DuckDB
'1.1' = 1	error	true
'1.1' = 1.1	true	true
1 = 1.1	false	false
true = 'true'	true	true
true = 1	error	true
'true' = 1	error	error

Case Sensitivity for Quoted Identifiers

PostgreSQL is case-insensitive. The way PostgreSQL achieves case insensitivity is by lowercasing unquoted identifiers within SQL, whereas quoting preserves case, e.g., the following command creates a table named `mytable` but tries to query for `MyTaBLe` because quotes preserve the case.

```
CREATE TABLE MyTaBLe (x INTEGER);
SELECT * FROM "MyTaBLe";
```

```
ERROR:  relation "MyTaBLe" does not exist
```

PostgreSQL does not only treat quoted identifiers as case-sensitive; it treats all identifiers as case-sensitive, e.g., this also does not work:

```
CREATE TABLE "PreservedCase" (x INTEGER);
SELECT * FROM PreservedCase;
```

```
ERROR:  relation "preservedcase" does not exist
```

Therefore, case-insensitivity in PostgreSQL only works if you never use quoted identifiers with different cases.

For DuckDB, this behavior was problematic when interfacing with other tools (e.g., Parquet, Pandas) that are case-sensitive by default – since all identifiers would be lowercased all the time. Therefore, DuckDB achieves case insensitivity by making identifiers fully case insensitive throughout the system but *preserving their case*.

In DuckDB, the scripts above complete successfully:

```
CREATE TABLE MyTaBLe (x INTEGER);
SELECT * FROM "MyTaBLe";
CREATE TABLE "PreservedCase" (x INTEGER);
SELECT * FROM PreservedCase;
SELECT tbl FROM duckdb_tables();
```

tbl
MyTaBLe
PreservedCase

PostgreSQL's behavior of lowercasing identifiers is accessible using the `preserve_identifier_case` option:

```
SET preserve_identifier_case = false;
CREATE TABLE MyTaBLe (x INTEGER);
SELECT tbl FROM duckdb_tables();
```

tbl
mytable

However, the case insensitive matching in the system for identifiers cannot be turned off.

Using Double Equality Sign for Comparison

DuckDB supports both = and == for equality comparison, while PostgreSQL only supports =.

```
SELECT 1 == 1 AS t;
```

DuckDB returns `true`, while PostgreSQL returns:

```
postgres=# SELECT 1 == 1 AS t;
ERROR:  operator does not exist: integer == integer
LINE 1: SELECT 1 == 1 AS t;
```

Note that the use of == is not encouraged due to its limited portability.

Vacuuming Tables

In PostgreSQL, the VACUUM statement garbage collects tables and analyzes tables. In DuckDB, the VACUUM statement is only used to rebuild statistics. For instruction on reclaiming space, refer to the "Reclaiming space" page.

Strings

Since version 1.3.0, DuckDB escapes characters such as `'` in strings serialized in nested data structures. PostgreSQL does not do this.

For an example, run:

```
SELECT ARRAY[''''];
```

PostgreSQL returns:

```
{'}
```

DuckDB returns:

```
['\'']
```

Functions

`regexp_extract` Function

Unlike PostgreSQL's `regexp_substr` function, DuckDB's `regexp_extract` returns empty strings instead of `NULL`s when there is no match.

`to_date` Function

DuckDB does not support the `to_date` PostgreSQL date formatting function. Instead, please use the `strptime` function.

`date_part` Function

Most parts extracted by the `date_part` function are returned as integers. Since there are no infinite integer values in DuckDB, `NULL`s are returned for infinite timestamps.

Resolution of Type Names in the Schema

For `CREATE TABLE` statements, DuckDB attempts to resolve type names in the schema where a table is created. For example:

```
CREATE SCHEMA myschema;
CREATE TYPE myschema.mytype AS ENUM ('as', 'df');
CREATE TABLE myschema.mytable (v mytype);
```

PostgreSQL returns an error on the last statement:

```
ERROR:  type "mytype" does not exist
LINE 1: CREATE TABLE myschema.mytable (v mytype);
```

DuckDB runs the statement and creates the table successfully, confirmed by the following query:

```
DESCRIBE myschema.mytable;
```

column_name	column_type	null	key	default	extra
v	ENUM('as', 'df')	YES	NULL	NULL	NULL

Exploiting Functional Dependencies for `GROUP BY`

PostgreSQL can exploit functional dependencies, such as `i -> j` in the following query:

```
CREATE TABLE tbl (i INTEGER, j INTEGER, PRIMARY KEY (i));
SELECT j
FROM tbl
GROUP BY i;
```

PostgreSQL runs the query.

DuckDB fails:

```
Binder Error:
column "j" must appear in the GROUP BY clause or must be part of an aggregate function.
Either add it to the GROUP BY list, or use "ANY_VALUE(j)" if the exact value of "j" is not important.
```

To work around this, add the other attributes or use the `GROUP BY ALL` clause.

Behavior of Regular Expression Match Operators

PostgreSQL supports the POSIX regular expression matching operators `~` (case-sensitive partial regex matching) and `~*` (case-insensitive partial regex matching) as well as their negated variants, `!~` and `!~*`, respectively.

In DuckDB, `~` is equivalent to `regexp_full_match` and `!~` is equivalent to `NOT regexp_full_match`. The operators `~*` and `!~*` are not supported.

The table below shows that the correspondence between these functions in PostgreSQL and DuckDB is almost non-existent. Avoid using the POSIX regular expression matching operators in DuckDB.

Expression	PostgreSQL	DuckDB
`'aaa' ~ '(a|b)'`	true	false
`'AAA' ~* '(a|b)'`	true	error
`'aaa' !~ '(a|b)'`	false	true
`'AAA' !~* '(a|b)'`	false	error

SQL Quirks

Like all programming languages and libraries, DuckDB has its share of idiosyncrasies and inconsistencies.
Some are vestiges of our feathered friend's evolution; others are inevitable because we strive to adhere to the SQL Standard and specifically to PostgreSQL's dialect (see the "PostgreSQL Compatibility" page for exceptions). The rest may simply come down to different preferences, or we may even agree on what *should* be done but just haven't gotten around to it yet.

Acknowledging these quirks is the best we can do, which is why we have compiled below a list of examples.

Aggregating Empty Groups

On empty groups, the aggregate functions `sum`, `list`, and `string_agg` all return `NULL` instead of `0`, `[]` and `''`, respectively. This is dictated by the SQL Standard and obeyed by all SQL implementations we know. This behavior is inherited by the list aggregate `list_sum`, but not by the DuckDB original `list_dot_product` which returns `0` on empty lists.

0 vs. 1-Based Indexing

To comply with standard SQL, one-based indexing is used almost everywhere, e.g., array and string indexing and slicing, and window functions (`row_number`, `rank`, `dense_rank`). However, similarly to PostgreSQL, JSON features use a zero-based indexing.

Types

`UINT8` vs. `INT8`

`UINT8` and `INT8` are aliases to integer types of different widths:

- `UINT8` corresponds to `UTINYINT` because it's an *8-bit* unsigned integer
- `INT8` corresponds to `BIGINT` because it's an *8-byte* signed integer

Explanation: the `n` in the numeric type `INTn` and `UINTn` denote the width of the number in either bytes or bits. `INT1`, `INT2`, `INT4` correspond to the number of bytes, while `INT16`, `INT32` and `INT64` correspond to the number of bits. The same applies to `UINT` values. However, the value `n = 8` is a valid choice for both the number of bits and bytes. For unsigned values, `UINT8` corresponds to `UTINYINT` (8 bits). For signed values, `INT8` corresponds to `BIGINT` (8 bytes).

Expressions

Results That May Surprise You

Expression	Result	Note
`-2^2`	`4.0`	PostgreSQL compatibility means the unary minus has higher precedence than the exponentiation operator. Use additional parentheses, e.g., `-(2^2)` or the pow function, e.g., `-pow(2, 2)`, to avoid mistakes.
`'t' = true`	`true`	Compatible with PostgreSQL.
`1 = '1'`	`true`	Compatible with PostgreSQL.
`1 = ' 1'`	`true`	Compatible with PostgreSQL.
`1 = '01'`	`true`	Compatible with PostgreSQL.
`1 = ' 01 '`	`true`	Compatible with PostgreSQL.
`1 = true`	`true`	Not compatible with PostgreSQL.
`1 = '1.1'`	`true`	Not compatible with PostgreSQL.
`1 IN (0, NULL)`	`NULL`	Makes sense if you think of the `NULL`s in the input and output as `UNKNOWN`.
`1 in [0, NULL]`	`false`	
`concat('abc', NULL)`	`abc`	Compatible with PostgreSQL. `list_concat` behaves similarly.
`'abc' || NULL`	`NULL`	

NaN Values

`'NaN'::FLOAT = 'NaN'::FLOAT` and `'NaN'::FLOAT > 3` violate IEEE-754 but mean floating point data types have a total order, like all other data types (beware the consequences for `greatest` / `least`).

age Function

`age(x)` is `current_date - x` instead of `current_timestamp - x`. Another quirk inherited from PostgreSQL.

Extract Functions

`list_extract` / `map_extract` return `NULL` on non-existing keys. `struct_extract` throws an error because keys of structs are like columns.

Clauses

Automatic Column Deduplication in SELECT

Column names are deduplicated with the first occurrence shadowing the others:

```
CREATE TABLE tbl AS SELECT 1 AS a;
SELECT a FROM (SELECT *, 2 AS a FROM tbl);
```

a
1

Case Insensitivity for SELECTing Columns

Due to case-insensitivity, it's not possible to use `SELECT a FROM 'file.parquet'` when a column called `A` appears before the desired column `a` in `file.parquet`.

`USING SAMPLE`

The `USING SAMPLE` clause is syntactically placed after the `WHERE` and `GROUP BY` clauses (same as the `LIMIT` clause) but is semantically applied before both (unlike the `LIMIT` clause).

PEG Parser

DuckDB v1.5 shipped an experimental parser based on PEG (Parser Expression Grammars). The new parser enables better suggestions, improved error messages, and allows extensions to extend the grammar. The PEG parser is currently disabled by default but you can opt-in using:

```
CALL enable_peg_parser();
```

The PEG parser is already used for generating suggestions. You can cycle through the options using TAB.

```
«animals_db» D FROM ducks WHERE habitat IS
IS           ISNULL       ILIKE        ⍰IN⍰          INTERSECT    LIKE
```

We are planning to make the switch to the new parser in the DuckDB v2.0 release.

> As a tradeoff, the parser has a slight performance overhead, however, this is in the range of milliseconds and is thus negligible for analytical queries. For more details on the rationale for using a PEG parser and benchmark results, please refer to the CIDR 2026 paper by Hannes Mühleisen and Mark Raasveldt, or their blog post summarizing the paper.

Samples

Samples are used to randomly select a subset of a dataset.

Examples

Select a sample of exactly 5 rows from `tbl` using `reservoir` sampling:

```
SELECT *
FROM tbl
USING SAMPLE 5;
```

Select a sample of *approximately* 10% of the table using `system` sampling:

```
SELECT *
FROM tbl
USING SAMPLE 10%;
```

> **Warning.** By default, when you specify a percentage, each *vector* is included in the sample with that probability. If your table contains fewer than ~10k rows, it makes sense to specify the `bernoulli` sampling option instead, which applies the probability to each row independently. Even then, you'll sometimes get more and sometimes less than the specified percentage of the number of rows, but it is much less likely that you get no rows at all. To get exactly 10% of rows (up to rounding), you must use the `reservoir` sampling option.

Select a sample of *approximately* 10% of the table using `bernoulli` sampling:

```
SELECT *
FROM tbl
USING SAMPLE 10 PERCENT (bernoulli);
```

Select a sample of *exactly* 10% (up to rounding) of the table using `reservoir` sampling:

```
SELECT *
FROM tbl
USING SAMPLE 10 PERCENT (reservoir);
```

Select a sample of *exactly* 50 rows of the table using reservoir sampling with a fixed seed (100):

```
SELECT *
FROM tbl
USING SAMPLE reservoir(50 ROWS)
REPEATABLE (100);
```

Select a sample of *approximately* 20% of the table using `system` sampling with a fixed seed (377):

```
SELECT *
FROM tbl
USING SAMPLE 20% (system, 377);
```

Select a sample of *approximately* 20% of `tbl` **before** the join with `tbl2`:

```
SELECT *
FROM tbl TABLESAMPLE reservoir(20%), tbl2
WHERE tbl.i = tbl2.i;
```

Select a sample of *approximately* 20% of `tbl` **after** the join with `tbl2`:

```
SELECT *
FROM tbl, tbl2
WHERE tbl.i = tbl2.i
USING SAMPLE reservoir(20%);
```

Syntax

Samples allow you to randomly extract a subset of a dataset. Samples are useful for exploring a dataset faster, as often you might not be interested in the exact answers to queries, but only in rough indications of what the data looks like and what is in the data. Samples allow you to get approximate answers to queries faster, as they reduce the amount of data that needs to pass through the query engine.

DuckDB supports three different types of sampling methods: `reservoir`, `bernoulli` and `system`. By default, DuckDB uses `reservoir` sampling when an exact number of rows is sampled, and `system` sampling when a percentage is specified. The sampling methods are described in detail below.

Samples require a *sample size*, which is an indication of how many elements will be sampled from the total population. Samples can either be given as a percentage (`10%` or `10 PERCENT`) or as a fixed number of rows (`10` or `10 ROWS`). All three sampling methods support sampling over a percentage, but **only** reservoir sampling supports sampling a fixed number of rows.

Samples are probabilistic, that is to say, samples can be different between runs *unless* the seed is specifically specified. Specifying the seed *only* guarantees that the sample is the same if multi-threading is not enabled (i.e., `SET threads = 1`). In the case of multiple threads running over a sample, samples are not necessarily consistent even with a fixed seed.

Sampling Methods

`reservoir`

Reservoir sampling is a stream sampling technique that selects a random sample by keeping a *reservoir* of size equal to the sample size, and randomly replacing elements as more elements come in. Reservoir sampling allows us to specify *exactly* how many elements we want in the resulting sample (by selecting the size of the reservoir). As a result, reservoir sampling *always* outputs the same amount of elements, unlike system and bernoulli sampling.

Reservoir sampling is only recommended for small sample sizes, and is not recommended for use with percentages. That is because reservoir sampling needs to materialize the entire sample and randomly replace tuples within the materialized sample. The larger the sample size, the higher the performance hit incurred by this process.

Reservoir sampling also incurs an additional performance penalty when multi-processing is used, since the reservoir is to be shared amongst the different threads to ensure unbiased sampling. This is not a big problem when the reservoir is very small, but becomes costly when the sample is large.

> **Best practice.** Avoid using reservoir sampling with large sample sizes if possible. Reservoir sampling requires the entire sample to be materialized in memory.

`bernoulli`

Bernoulli sampling can only be used when a sampling percentage is specified. It is rather straightforward: every row in the underlying table is included with a chance equal to the specified percentage. As a result, bernoulli sampling can return a different number of tuples even if the same percentage is specified. The *expected* number of rows is equal to the specified percentage of the table, but there will be some *variance*.

Because bernoulli sampling is completely independent (there is no shared state), there is no penalty for using bernoulli sampling together with multiple threads.

`system`

System sampling is a variant of bernoulli sampling with one crucial difference: every *vector* is included with a chance equal to the sampling percentage. This is a form of cluster sampling. System sampling is more efficient than bernoulli sampling, as no per-tuple selections have to be performed.

The *expected* number of rows is still equal to the specified percentage of the table, but the *variance* is `vectorSize` times higher. As such, system sampling is not suitable for datasets with fewer than ~10k rows, where it can happen that all rows will be filtered out, or all the data will be included, even when you ask for `50 PERCENT`.

Table Samples

The `TABLESAMPLE` and `USING SAMPLE` clauses are identical in terms of syntax and effect, with one important difference: tablesamples sample directly from the table for which they are specified, whereas the sample clause samples after the entire from clause has been resolved. This is relevant when there are joins present in the query plan.

The `TABLESAMPLE` clause is essentially equivalent to creating a subquery with the `USING SAMPLE` clause, i.e., the following two queries are identical:

Sample 20% of `tbl` **before** the join:

```
SELECT *
FROM
    tbl TABLESAMPLE reservoir(20%),
    tbl2
WHERE tbl.i = tbl2.i;
```

Sample 20% of `tbl` **before** the join:

```
SELECT *
FROM
    (SELECT * FROM tbl USING SAMPLE reservoir(20%)) tbl,
    tbl2
WHERE tbl.i = tbl2.i;
```

Sample 20% **after** the join (i.e., sample 20% of the join result):

```
SELECT *
FROM tbl, tbl2
WHERE tbl.i = tbl2.i
USING SAMPLE reservoir(20%);
```

Configuration

Configuration

DuckDB has a number of configuration options that can be used to change the behavior of the system.

The configuration options can be set using either the SET statement or the PRAGMA statement. They can be reset to their original values using the RESET statement.

The values of configuration options can be queried via the `current_setting()` scalar function or using the `duckdb_settings()` table function. For example:

```sql
SELECT current_setting('memory_limit') AS memlimit;
```

Or:

```sql
SELECT value AS memlimit
FROM duckdb_settings()
WHERE name = 'memory_limit';
```

Examples

Set the memory limit of the system to 10 GB.

```sql
SET memory_limit = '10GB';
```

Configure the system to use 1 thread.

```sql
SET threads TO 1;
```

Turn logging on and set the logging level to `debug`. For additional details on logging levels, see Log Level.

```sql
SET enable_logging = true;
SET logging_level = 'debug';
```

Write a single log message with the `debug` level and a `connection` scope:

```sql
SELECT write_log('A new client has connected.', level := 'debug', scope := 'connection');
```

Write a single log message with a `debug` level and a `connection` scope and a custom `log_type`:

```sql
SELECT write_log(
        'A new duck has connected to the lake.',
        level := 'debug',
        scope := 'connection',
        log_type := 'duckdb.docs.example.quack'
    );
```

Check logs with the DEBUG log level:

```sql
SELECT * FROM duckdb_logs WHERE log_level = 'DEBUG';
```

Check logs with the `QueryLog` type:

```sql
SELECT * FROM duckdb_logs WHERE type = 'QueryLog';
```

Check current logging settings:

```sql
SELECT * FROM duckdb_settings() WHERE name LIKE '%logging%';
```

Enable printing of a progress bar during long-running queries:

```
SET enable_progress_bar = true;
```

Set the default null order to `NULLS LAST`:

```
SET default_null_order = 'nulls_last';
```

Return the current value of a specific setting:

```
SELECT current_setting('threads') AS threads;
```

threads
10

Query a specific setting:

```
SELECT *
FROM duckdb_settings()
WHERE name = 'threads';
```

name	value	description	input_type	scope
threads	1	The number of total threads used by the system.	BIGINT	GLOBAL

Show a list of all available settings:

```
SELECT *
FROM duckdb_settings();
```

Reset the memory limit of the system back to the default:

```
RESET memory_limit;
```

Secrets Manager

DuckDB has a Secrets manager, which provides a unified user interface for secrets across all backends (e.g., AWS S3) that use them.

Configuration Reference

Configuration options come with different default scopes: `GLOBAL` and `LOCAL`. Below is a list of all available configuration options by scope.

Global Configuration Options

Name	Description	Type	Default value
`Calendar`	The current calendar	VARCHAR	System (locale) calendar
`TimeZone`	The current time zone	VARCHAR	System (locale) timezone

Name	Description	Type	Default value
`__delta_only_variant_encoding_enabled`	Enables the Parquet reader to identify a Variant structurally.	`BOOLEAN`	`false`
`access_mode`	Access mode of the database (`AUTOMATIC`, `READ_ONLY` or `READ_WRITE`)	`VARCHAR`	`automatic`
`allocator_background_threads`	Whether to enable the allocator background thread.	`BOOLEAN`	`false`
`allocator_bulk_deallocation_flush_threshold`	If a bulk deallocation larger than this occurs, flush outstanding allocations.	`VARCHAR`	`512.0 MiB`
`allocator_flush_threshold`	Peak allocation threshold at which to flush the allocator after completing a task.	`VARCHAR`	`128.0 MiB`
`allow_asterisks_in_http_paths`	Allow '*' character in URLs users can query	`BOOLEAN`	`false`
`allow_community_extensions`	Allow to load community built extensions	`BOOLEAN`	`true`
`allow_extensions_metadata_mismatch`	Allow to load extensions with not compatible metadata	`BOOLEAN`	`false`
`allow_parser_override_extension`	Allow extensions to override the current parser	`VARCHAR`	`DEFAULT`
`allow_persistent_secrets`	Allow the creation of persistent secrets, that are stored and loaded on restarts	`BOOLEAN`	`true`
`allow_unredacted_secrets`	Allow printing unredacted secrets	`BOOLEAN`	`false`
`allow_unsigned_extensions`	Allow to load extensions with invalid or missing signatures	`BOOLEAN`	`false`
`allowed_configs`	List of configuration options that are ALWAYS allowed to be changed - even when lock_configuration is true	`VARCHAR[]`	`[]`
`allowed_directories`	List of directories/prefixes that are ALWAYS allowed to be queried - even when enable_external_access is false	`VARCHAR[]`	`[]`
`allowed_paths`	List of files that are ALWAYS allowed to be queried - even when enable_external_access is false	`VARCHAR[]`	`[]`
`arrow_large_buffer_size`	Whether Arrow buffers for strings, blobs, uuids and bits should be exported using large buffers	`BOOLEAN`	`false`
`arrow_lossless_conversion`	Whenever a DuckDB type does not have a clear native or canonical extension match in Arrow, export the types with a duckdb.type_name extension name.	`BOOLEAN`	`false`
`arrow_output_list_view`	Whether export to Arrow format should use ListView as the physical layout for LIST columns	`BOOLEAN`	`false`
`arrow_output_version`	Whether strings should be produced by DuckDB in Utf8View format instead of Utf8	`VARCHAR`	`1.0`
`asof_loop_join_threshold`	The maximum number of rows we need on the left side of an ASOF join to use a nested loop join	`UBIGINT`	`64`

Name	Description	Type	Default value
auto_checkpoint_skip_wal_threshold	The estimated WAL write size at which point we will skip writing to the WAL and only checkpoint. Skipping writing to the WAL means concurrent commits are blocked while the checkpoint is happening.	UBIGINT	100000
auto_fallback_to_full_download	Allows automatically falling back to full file downloads when possible.	BOOLEAN	true
autoinstall_extension_repository	Overrides the custom endpoint for extension installation on autoloading	VARCHAR	
autoinstall_known_extensions	Whether known extensions are allowed to be automatically installed when a query depends on them	BOOLEAN	true
autoload_known_extensions	Whether known extensions are allowed to be automatically loaded when a query depends on them	BOOLEAN	true
binary_as_string	In Parquet files, interpret binary data as a string.	BOOLEAN	false
block_allocator_memory	Physical memory that the block allocator is allowed to use (this memory is never freed and cannot be reduced).	VARCHAR	0 bytes
ca_cert_file	Path to a custom certificate file for self-signed certificates.	VARCHAR	
catalog_error_max_schemas	The maximum number of schemas the system will scan for "did you mean..." style errors in the catalog	UBIGINT	100
checkpoint_threshold, wal_autocheckpoint	The WAL size threshold at which to automatically trigger a checkpoint (e.g., 1GB)	VARCHAR	16.0 MiB
current_transaction_invalidation_policy	Which types of exceptions invalidate the database for the current transaction	VARCHAR	STANDARD_POLICY
custom_extension_repository	Overrides the custom endpoint for remote extension installation	VARCHAR	
custom_user_agent	Metadata from DuckDB callers	VARCHAR	
default_block_size	The default block size for new duckdb database files (new as-in, they do not yet exist).	UBIGINT	262144
default_collation	The collation setting used when none is specified	VARCHAR	
default_null_order, null_order	NULL ordering used when none is specified (NULLS_FIRST or NULLS_LAST)	VARCHAR	NULLS_LAST
default_order	The order type used when none is specified (ASC or DESC)	VARCHAR	ASCENDING
default_secret_storage	Allows switching the default storage for secrets	VARCHAR	local_file
deprecated_using_key_syntax	Configures the use of the deprecated union syntax for USING KEY CTEs.	VARCHAR	DEFAULT
disable_database_invalidation	Disables invalidating the database instance when encountering a fatal error. Should be used with great care, as DuckDB cannot guarantee correct behavior after a fatal error.	BOOLEAN	false
disable_parquet_prefetching	Disable the prefetching mechanism in Parquet	BOOLEAN	false
disable_timestamptz_casts	Disable casting from timestamp to timestamptz	BOOLEAN	false

Name	Description	Type	Default value
disabled_compression_methods	Disable a specific set of compression methods (comma separated)	VARCHAR	
disabled_filesystems	Disable specific file systems preventing access (e.g., LocalFileSystem)	VARCHAR	
disabled_log_types	Sets the list of disabled loggers	VARCHAR	
disabled_optimizers	Disable a specific set of optimizers (comma separated)	VARCHAR	
duckdb_api	DuckDB API surface	VARCHAR	cli
dynamic_or_filter_threshold	The maximum amount of OR filters we generate dynamically from a hash join	UBIGINT	50
enable_curl_server_cert_verification	Enable server side certificate verification for CURL backend.	BOOLEAN	true
enable_external_access	Allow the database to access external state (through e.g., loading/installing modules, COPY TO/FROM, CSV readers, pandas replacement scans, etc)	BOOLEAN	true
enable_external_file_cache	Allow the database to cache external files (e.g., Parquet) in memory.	BOOLEAN	true
enable_fsst_vectors	Allow scans on FSST compressed segments to emit compressed vectors to utilize late decompression	BOOLEAN	false
enable_geoparquet_conversion	Attempt to decode/encode geometry data in/as GeoParquet files if the spatial extension is present.	BOOLEAN	true
enable_global_s3_configuration	Automatically fetch AWS credentials from environment variables.	BOOLEAN	true
enable_http_metadata_cache	Whether or not the global http metadata is used to cache HTTP metadata	BOOLEAN	false
enable_logging	Enables the logger	BOOLEAN	1
enable_macro_dependencies	Enable created MACROs to create dependencies on the referenced objects (such as tables)	BOOLEAN	false
enable_object_cache	[PLACEHOLDER] Legacy setting - does nothing	BOOLEAN	false
enable_server_cert_verification	Enable server side certificate verification.	BOOLEAN	false
enable_view_dependencies	Enable created VIEWs to create dependencies on the referenced objects (such as tables)	BOOLEAN	false
enabled_log_types	Sets the list of enabled loggers	VARCHAR	
errors_as_json	Output error messages as structured JSON instead of as a raw string	BOOLEAN	false
experimental_metadata_reuse	EXPERIMENTAL: Re-use row group and table metadata when checkpointing.	BOOLEAN	true
explain_output	Output of EXPLAIN statements (ALL, OPTIMIZED_ONLY, PHYSICAL_ONLY)	VARCHAR	PHYSICAL_ONLY
extension_directories	Set the directories to store extensions in	VARCHAR[]	[]
extension_directory	Set the directory to store extensions in	VARCHAR	
external_threads	The number of external threads that work on DuckDB tasks.	UBIGINT	1
file_search_path	A comma separated list of directories to search for input files	VARCHAR	

Name	Description	Type	Default value
force_download_threshold	Forces upfront download of files smaller than the given size in bytes	UBIGINT	0
force_download	Forces upfront download of file	BOOLEAN	false
force_mbedtls_unsafe	Enable mbedtls for encryption (WARNING: unsafe to use)	BOOLEAN	false
force_variant_shredding	Forces the VARIANT shredding that happens at checkpoint to use the provided schema for the shredding.	VARCHAR	INVALID
geometry_minimum_shredding_size	Minimum size of a rowgroup to enable GEOMETRY shredding, or set to -1 to disable entirely. Defaults to 1/4th of a rowgroup	BIGINT	30000
home_directory	Sets the home directory used by the system	VARCHAR	
http_keep_alive	Keep alive connections. Setting this to false can help when running into connection failures	BOOLEAN	true
http_proxy_password	Password for HTTP proxy	VARCHAR	
http_proxy_username	Username for HTTP proxy	VARCHAR	
http_proxy	HTTP proxy host	VARCHAR	
http_retries	HTTP retries on I/O error	UBIGINT	3
http_retry_backoff	Backoff factor for exponentially increasing retry wait time	FLOAT	4
http_retry_wait_ms	Time between retries	UBIGINT	100
http_timeout	HTTP timeout read/write/connection/retry (in seconds)	UBIGINT	30
httpfs_client_implementation	Select which is the HTTPUtil implementation to be used	VARCHAR	default
httpfs_connection_caching	Enable connection caching for HTTP requests	BOOLEAN	false
ieee_floating_point_ops	Use IEE754-compliant floating point operations (returning NAN instead of errors/NULL).	BOOLEAN	true
ignore_unknown_crs	Ignore unknown Coordinate Reference Systems (CRS) when creating geometry types or importing geospatial data.	BOOLEAN	false
immediate_transaction_mode	Whether transactions should be started lazily when needed, or immediately when BEGIN TRANSACTION is called	BOOLEAN	false
index_scan_max_count	The maximum index scan count sets a threshold for index scans. If fewer than MAX(index_scan_max_count, index_scan_percentage * total_row_count) rows match, we perform an index scan instead of a table scan.	UBIGINT	2048
index_scan_percentage	The index scan percentage sets a threshold for index scans. If fewer than MAX(index_scan_max_count, index_scan_percentage * total_row_count) rows match, we perform an index scan instead of a table scan.	DOUBLE	0.001
integer_division	Whether or not the / operator defaults to integer division, or to floating point division	BOOLEAN	false
lambda_syntax	Configures the use of the deprecated single arrow operator (->) for lambda functions.	VARCHAR	DEFAULT
late_materialization_max_rows	The maximum amount of rows in the LIMIT/SAMPLE for which we trigger late materialization	UBIGINT	50

Name	Description	Type	Default value
lock_configuration	Whether or not configurations can be altered	BOOLEAN	false
log_query_path	Specifies the path to which queries should be logged (default: NULL, queries are not logged)	VARCHAR	
logging_level	The log level which will be recorded in the log	VARCHAR	WARNING
logging_mode	Determines which types of log messages are logged	VARCHAR	LEVEL_ONLY
logging_storage	Set the logging storage (memory/stdout/file/)	VARCHAR	shell_log_storage
max_expression_depth	The maximum expression depth limit in the parser. WARNING: increasing this setting and using very deep expressions might lead to stack overflow errors.	UBIGINT	1000
max_memory, memory_limit	The maximum memory of the system (e.g., 1GB)	VARCHAR	80% of RAM
max_temp_directory_size	The maximum amount of data stored inside the 'temp_directory' (when set) (e.g., 1GB)	VARCHAR	90% of available disk space
max_vacuum_tasks	The maximum vacuum tasks to schedule during a checkpoint.	UBIGINT	100
merge_http_secret_into_s3_request	Merges http secret params into S3 requests	BOOLEAN	true
merge_join_threshold	The maximum number of rows on either table to choose a merge join	UBIGINT	1000
nested_loop_join_threshold	The maximum number of rows on either table to choose a nested loop join	UBIGINT	5
old_implicit_casting	Allow implicit casting to/from VARCHAR	BOOLEAN	false
order_by_non_integer_literal	Allow ordering by non-integer literals - ordering by such literals has no effect.	BOOLEAN	false
ordered_aggregate_threshold	The number of rows to accumulate before sorting, used for tuning	UBIGINT	262144
parquet_metadata_cache	Cache Parquet metadata - useful when reading the same files multiple times	BOOLEAN	false
partitioned_write_flush_threshold	The threshold in number of rows after which we flush a thread state when writing using PARTITION_BY	UBIGINT	524288
partitioned_write_max_open_files	The maximum amount of files the system can keep open before flushing to disk when writing using PARTITION_BY	UBIGINT	100
password	The password to use. Ignored for legacy compatibility.	VARCHAR	
perfect_ht_threshold	Threshold in bytes for when to use a perfect hash table	UBIGINT	12
pin_threads	Whether to pin threads to cores (Linux only, default AUTO: on when there are more than 64 cores)	VARCHAR	auto
pivot_filter_threshold	The threshold to switch from using filtered aggregates to LIST with a dedicated pivot operator	UBIGINT	20
pivot_limit	The maximum number of pivot columns in a pivot statement	UBIGINT	100000
prefer_range_joins	Force use of range joins with mixed predicates	BOOLEAN	false

Name	Description	Type	Default value
prefetch_all_parquet_files	Use the prefetching mechanism for all types of parquet files	BOOLEAN	false
preserve_identifier_case	Whether or not to preserve the identifier case, instead of always lowercasing all non-quoted identifiers	BOOLEAN	true
preserve_insertion_order	Whether or not to preserve insertion order. If set to false the system is allowed to re-order any results that do not contain ORDER BY clauses.	BOOLEAN	true
produce_arrow_string_view	Whether Arrow strings should be produced by DuckDB in Utf8View format instead of Utf8	BOOLEAN	false
s3_access_key_id	S3 Access Key ID	VARCHAR	NULL
s3_allow_recursive_globbing	Whether globs on S3-like storage are optimized with recursive strategy (alterative is listing)	BOOLEAN	true
s3_endpoint	S3 Endpoint	VARCHAR	NULL
s3_kms_key_id	S3 KMS Key ID	VARCHAR	NULL
s3_region	S3 Region	VARCHAR	NULL
s3_requester_pays	S3 use requester pays mode	BOOLEAN	false
s3_secret_access_key	S3 Access Key	VARCHAR	NULL
s3_session_token	S3 Session Token	VARCHAR	NULL
s3_uploader_max_filesize	S3 Uploader max filesize (between 50GB and 5TB)	VARCHAR	800GB
s3_uploader_max_parts_per_file	S3 Uploader max parts per file (between 1 and 10000)	UBIGINT	10000
s3_uploader_thread_limit	S3 Uploader global thread limit	UBIGINT	50
s3_url_compatibility_mode	Disable Globs and Query Parameters on S3 URLs	BOOLEAN	false
s3_url_style	S3 URL style	VARCHAR	vhost
s3_use_ssl	S3 use SSL	BOOLEAN	true
s3_version_id_pinning	Pin S3 reads to a specific object version for consistency	BOOLEAN	false
scalar_subquery_error_on_multiple_rows	When a scalar subquery returns multiple rows - return a random row instead of returning an error.	BOOLEAN	true
scheduler_process_partial	Partially process tasks before rescheduling - allows for more scheduler fairness between separate queries	BOOLEAN	false
secret_directory	Set the directory to which persistent secrets are stored	VARCHAR	~/.duckdb/stored_secrets
storage_block_prefetch	In which scenarios to use storage block prefetching	VARCHAR	REMOTE_ONLY
storage_compatibility_version	Serialize on checkpoint with compatibility for a given duckdb version	VARCHAR	v0.10.2

Name	Description	Type	Default value
`temp_directory`	Set the directory to which to write temp files	`VARCHAR`	`<database_name>.tmp` or `.tmp` (in in-memory mode)
`temp_file_encryption`	Encrypt all temporary files if database is encrypted	`BOOLEAN`	`false`
`threads`, `worker_threads`	The number of total threads used by the system.	`BIGINT`	# CPU cores
`unsafe_disable_etag_checks`	Disable checks on ETag consistency	`BOOLEAN`	`false`
`user`, `username`	The username to use. Ignored for legacy compatibility.	`VARCHAR`	
`vacuum_rebuild_indexes`	(Experimental) Allow vacuum to compact row groups on tables with bound ART indexes, rebuilding the indexes afterward. Tables with a row count exceeding this threshold are skipped. 0 = disabled.	`UBIGINT`	`0`
`validate_external_file_cache`	Cache validation mode: VALIDATE_ALL (default, validate all cache entries), VALIDATE_REMOTE (validate only remote cache entries), or NO_VALIDATION (disable cache validation).	`VARCHAR`	`VALIDATE_ALL`
`variant_minimum_shredding_size`	Minimum size of a rowgroup to enable VARIANT shredding, or set to -1 to disable entirely. Defaults to 1/4th of a rowgroup	`BIGINT`	`30000`
`wal_autocheckpoint_entries`	Trigger automatic checkpoint when WAL entry count reaches or exceeds N (0 = disabled)	`UBIGINT`	`0`
`warnings_as_errors`	Escalate all warnings to errors.	`BOOLEAN`	`false`
`write_buffer_row_group_count`	The amount of row groups to buffer in bulk ingestion prior to flushing them together. Reducing this setting can reduce memory consumption.	`UBIGINT`	`5`
`write_buffer_row_group_memory_limit`	The maximum data to buffer in row groups (in bytes) prior to flushing them together. When either this limit or `write_buffer_row_group_count` is reached, the data is flushed to disk. Defaults to 20% of the memory limit divided by the thread count.	`VARCHAR`	
`zstd_min_string_length`	The (average) length at which to enable ZSTD compression, defaults to 4096	`UBIGINT`	`4096`

Local Configuration Options

Name	Description	Type	Default value

| Name | Description | Type | Default value |

`custom_profiling_settings`	Accepts a JSON enabling custom metrics	VARCHAR	`{"ATTACH_LOAD_STORAGE_LATENCY": "true", "ATTACH_REPLAY_WAL_LATENCY": "true", "BLOCKED_THREAD_TIME": "true", "CHECKPOINT_LATENCY": "true", "COMMIT_LOCAL_STORAGE_LATENCY": "true", "CPU_TIME": "true", "CUMULATIVE_CARDINALITY": "true", "CUMULATIVE_ROWS_SCANNED": "true", "EXTRA_INFO": "true", "LATENCY": "true", "OPERATOR_CARDINALITY": "true", "OPERATOR_NAME": "true", "OPERATOR_ROWS_SCANNED": "true", "OPERATOR_TIMING": "true", "OPERATOR_TYPE": "true", "QUERY_NAME": "true", "RESULT_SET_SIZE": "true", "ROWS_RETURNED": "true", "SYSTEM_PEAK_BUFFER_MEMORY": "true", "SYSTEM_PEAK_TEMP_DIR_SIZE": "true", "TOTAL_BYTES_READ": "true", "TOTAL_BYTES_WRITTEN":`

Name	Description	Type	Default value
enable_caching_operators	Enables caching operators that cache intermediate results	BOOLEAN	true
enable_http_logging	(deprecated) Enables HTTP logging	BOOLEAN	true
enable_profiling	Enables profiling, and sets the output format (JSON, QUERY_TREE, QUERY_TREE_OPTIMIZER)	VARCHAR	NULL
enable_progress_bar_print	Controls the printing of the progress bar, when 'enable_progress_bar' is true	BOOLEAN	true
enable_progress_bar	Enables the progress bar, printing progress to the terminal for long queries	BOOLEAN	true
http_logging_output	(deprecated) The file to which HTTP logging output should be saved, or empty to print to the terminal	VARCHAR	
profile_output, profiling_output	The file to which profile output should be saved, or empty to print to the terminal	VARCHAR	
profiling_coverage	The profiling coverage (SELECT or ALL)	VARCHAR	SELECT
profiling_mode	The profiling mode (STANDARD or DETAILED)	VARCHAR	NULL
progress_bar_time	Sets the time (in milliseconds) how long a query needs to take before we start printing a progress bar	BIGINT	2000
schema	Sets the default search schema. Equivalent to setting search_path to a single value.	VARCHAR	main
search_path	Sets the default catalog search path as a comma-separated list of values	VARCHAR	
streaming_buffer_size	The maximum memory to buffer between fetching from a streaming result (e.g., 1GB)	VARCHAR	976.5 KiB

Pragmas

The PRAGMA statement is a SQL extension adopted by DuckDB from SQLite. PRAGMA statements can be issued in a similar manner to regular SQL statements. PRAGMA commands may alter the internal state of the database engine, and can influence the subsequent execution or behavior of the engine.

PRAGMA statements that assign a value to an option can also be issued using the SET statement and the value of an option can be retrieved using `SELECT current_setting(option_name)`.

For DuckDB's built in configuration options, see the Configuration Reference. DuckDB extensions may register additional configuration options. These are documented in the respective extensions' documentation pages.

This page contains the supported PRAGMA settings.

Metadata

Schema Information List all databases:

```
PRAGMA database_list;
```

List all tables:

```
PRAGMA show_tables;
```

List all tables, with extra information, similarly to `DESCRIBE`:

```
PRAGMA show_tables_expanded;
```

To list all functions:

```
PRAGMA functions;
```

For queries targeting non-existing schemas, DuckDB generates "did you mean..." style error messages. When there are thousands of attached databases, these errors can take a long time to generate. To limit the number of schemas DuckDB looks through, use the `catalog_error_max_schemas` option:

```
SET catalog_error_max_schemas = 10;
```

Table Information Get info for a specific table:

```
PRAGMA table_info('table_name');
CALL pragma_table_info('table_name');
```

`table_info` returns information about the columns of the table with name `table_name`. The exact format of the table returned is given below:

```
cid INTEGER,        -- cid of the column
name VARCHAR,       -- name of the column
type VARCHAR,       -- type of the column
notnull BOOLEAN,    -- if the column is marked as NOT NULL
dflt_value VARCHAR, -- default value of the column, or NULL if not specified
pk BOOLEAN          -- part of the primary key or not
```

Database Size Get the file and memory size of each database:

```
PRAGMA database_size;
CALL pragma_database_size();
```

`database_size` returns information about the file and memory size of each database. The column types of the returned results are given below:

```
database_name VARCHAR, -- database name
database_size VARCHAR, -- total block count times the block size
block_size BIGINT,     -- database block size
total_blocks BIGINT,   -- total blocks in the database
used_blocks BIGINT,    -- used blocks in the database
free_blocks BIGINT,    -- free blocks in the database
wal_size VARCHAR,      -- write ahead log size
memory_usage VARCHAR,  -- memory used by the database buffer manager
memory_limit VARCHAR   -- maximum memory allowed for the database
```

Storage Information To get storage information:

```
PRAGMA storage_info('table_name');
CALL pragma_storage_info('table_name');
```

This call returns the following information for the given table:

Name	Type	Description
`row_group_id`	`BIGINT`	
`column_name`	`VARCHAR`	
`column_id`	`BIGINT`	
`column_path`	`VARCHAR`	
`segment_id`	`BIGINT`	
`segment_type`	`VARCHAR`	
`start`	`BIGINT`	The start row id of this chunk
`count`	`BIGINT`	The amount of entries in this storage chunk
`compression`	`VARCHAR`	Compression type used for this column – see the "Lightweight Compression in DuckDB" blog post
`stats`	`VARCHAR`	
`has_updates`	`BOOLEAN`	
`persistent`	`BOOLEAN`	`false` if temporary table
`block_id`	`BIGINT`	Empty unless persistent
`block_offset`	`BIGINT`	Empty unless persistent

See Storage for more information.

Show Databases The following statement is equivalent to the `SHOW DATABASES` statement:

```
PRAGMA show_databases;
```

Resource Management

Memory Limit Set the memory limit for the buffer manager:

```
SET memory_limit = '1GB';
```

> **Warning.** The specified memory limit is only applied to the buffer manager. For most queries, the buffer manager handles the majority of the data processed. However, certain in-memory data structures such as vectors and query results are allocated outside of the buffer manager. Additionally, aggregate functions with complex state (e.g., `list`, `mode`, `quantile`, `string_agg`, and `approx` functions) use memory outside of the buffer manager. Therefore, the actual memory consumption can be higher than the specified memory limit.

Threads Set the amount of threads for parallel query execution:

```
SET threads = 4;
```

Collations

List all available collations:

```
PRAGMA collations;
```

Set the default collation to one of the available ones:

```
SET default_collation = 'nocase';
```

Default Ordering for NULLs

Set the default ordering for NULLs to be either `NULLS_FIRST`, `NULLS_LAST`, `NULLS_FIRST_ON_ASC_LAST_ON_DESC` or `NULLS_LAST_ON_ASC_FIRST_ON_DESC`:

```
SET default_null_order = 'NULLS_FIRST';
SET default_null_order = 'NULLS_LAST_ON_ASC_FIRST_ON_DESC';
```

Set the default result set ordering direction to `ASCENDING` or `DESCENDING`:

```
SET default_order = 'ASCENDING';
SET default_order = 'DESCENDING';
```

Ordering by Non-Integer Literals

By default, ordering by non-integer literals is not allowed:

```
SELECT 42 ORDER BY 'hello world';
```

```
-- Binder Error: ORDER BY non-integer literal has no effect.
```

To allow this behavior, use the `order_by_non_integer_literal` option:

```
SET order_by_non_integer_literal = true;
```

Implicit Casting to VARCHAR

Prior to version 0.10.0, DuckDB would automatically allow any type to be implicitly cast to VARCHAR during function binding. As a result it was possible to e.g., compute the substring of an integer without using an explicit cast. For version v0.10.0 and later an explicit cast is needed instead. To revert to the old behavior that performs implicit casting, set the `old_implicit_casting` variable to `true`:

```
SET old_implicit_casting = true;
```

Python: Scan All Dataframes

Prior to version 1.1.0, DuckDB's replacement scan mechanism in Python scanned the global Python namespace. To revert to this old behavior, use the following setting:

```
SET python_scan_all_frames = true;
```

Information on DuckDB

Version Show DuckDB version:

```
PRAGMA version;
CALL pragma_version();
```

Platform `platform` returns an identifier for the platform the current DuckDB executable has been compiled for, e.g., `osx_arm64`. The format of this identifier matches the platform name as described in the extension loading explainer:

```
PRAGMA platform;
CALL pragma_platform();
```

User Agent The following statement returns the user agent information, e.g., `duckdb/v0.10.0(osx_arm64)`:

```
PRAGMA user_agent;
```

Metadata Information The following statement returns information on the metadata store (`block_id`, `total_blocks`, `free_blocks`, and `free_list`):

```
PRAGMA metadata_info;
```

Progress Bar

Show progress bar when running queries:

```
PRAGMA enable_progress_bar;
```

Or:

```
PRAGMA enable_print_progress_bar;
```

Don't show a progress bar for running queries:

```
PRAGMA disable_progress_bar;
```

Or:

```
PRAGMA disable_print_progress_bar;
```

EXPLAIN Output

The output of `EXPLAIN` can be configured to show only the physical plan.

The default configuration of `EXPLAIN`:

```
SET explain_output = 'physical_only';
```

To only show the optimized query plan:

```
SET explain_output = 'optimized_only';
```

To show all query plans:

```
SET explain_output = 'all';
```

Profiling

Enable Profiling

The following query enables profiling with the default format, `query_tree`. Independent of the format, `enable_profiling` is **mandatory** to enable profiling.

```
PRAGMA enable_profiling;
PRAGMA enable_profile;
```

Profiling Coverage

By default, the profiling coverage is set to `SELECT`. `SELECT` runs the profiler for each operator in the physical plan of a `SELECT` statement.

```
SET profiling_coverage = 'SELECT';
```

By default, the profiler **does not** emit profiling information for other statement types (`INSERT INTO`, `ATTACH`, etc.). To run the profiler for all statement types, change this setting to `ALL`.

```
SET profiling_coverage = 'ALL';
```

Profiling Format

The format of `enable_profiling` can be specified as `query_tree`, `json`, `query_tree_optimizer`, or `no_output`. Each format prints its output to the configured output, except `no_output`.

The default format is `query_tree`. It prints the physical query plan and the metrics of each operator in the tree.

```
SET enable_profiling = 'query_tree';
```

Alternatively, `json` returns the physical query plan as JSON:

```
SET enable_profiling = 'json';
```

> **Tip.** To visualize query plans, consider using the DuckDB execution plan visualizer developed by the Database Systems Research Group at the University of Tübingen.

To return the physical query plan, including optimizer and planner metrics:

```
SET enable_profiling = 'query_tree_optimizer';
```

Database drivers and other applications can also access profiling information through API calls, in which case users can disable any other output. Even though the parameter reads `no_output`, it is essential to note that this **only** affects printing to the configurable output. When accessing profiling information through API calls, it is still crucial to enable profiling:

```
SET enable_profiling = 'no_output';
```

Profiling Output

By default, DuckDB prints profiling information to the standard output. However, if you prefer to write the profiling information to a file, you can use PRAGMA `profiling_output` to specify a filepath.

> **Warning.** The file contents will be overwritten for every newly issued query. Hence, the file will only contain the profiling information of the last run query:

```
SET profiling_output = '/path/to/file.json';
SET profile_output = '/path/to/file.json';
```

Profiling Mode

By default, a limited amount of profiling information is provided (`standard`).

```
SET profiling_mode = 'standard';
```

For more details, use the detailed profiling mode by setting `profiling_mode` to `detailed`. The output of this mode includes profiling of the planner and optimizer stages.

```
SET profiling_mode = 'detailed';
```

To access all available metrics, set the `profiling_mode` to `all`.

```
SET profiling_mode = 'all';
```

Custom Metrics

By default, profiling enables all metrics except those activated by detailed profiling.

Using the `custom_profiling_settings` PRAGMA, each metric, including those from detailed profiling, can be individually enabled or disabled. This PRAGMA accepts a JSON object with metric names as keys and Boolean values to toggle them on or off. Settings specified by this PRAGMA override the default behavior.

> **Note.** This only affects the metrics when the `enable_profiling` is set to `json` or `no_output`. The `query_tree` and `query_tree_optimizer` always use a default set of metrics.

In the following example, the `CPU_TIME` metric is disabled. The `EXTRA_INFO`, `OPERATOR_CARDINALITY`, and `OPERATOR_TIMING` metrics are enabled.

```
SET custom_profiling_settings = '{"CPU_TIME": "false", "EXTRA_INFO": "true", "OPERATOR_CARDINALITY":
"true", "OPERATOR_TIMING": "true"}';
```

The profiling documentation contains an overview of the available metrics.

Disable Profiling

To disable profiling:

```
PRAGMA disable_profiling;
PRAGMA disable_profile;
```

Query Optimization

Optimizer To disable the query optimizer:

```
PRAGMA disable_optimizer;
```

To enable the query optimizer:

```
PRAGMA enable_optimizer;
```

Selectively Disabling Optimizers The `disabled_optimizers` option allows selectively disabling optimization steps. For example, to disable `filter_pushdown` and `statistics_propagation`, run:

```
SET disabled_optimizers = 'filter_pushdown,statistics_propagation';
```

The available optimizations can be queried using the `duckdb_optimizers()` table function.

To re-enable the optimizers, run:

```
SET disabled_optimizers = '';
```

> **Warning.** The `disabled_optimizers` option should only be used for debugging performance issues and should be avoided in production.

Logging

Set a path for query logging:

```
SET log_query_path = '/tmp/duckdb_log/';
```

Disable query logging:

```
SET log_query_path = '';
```

Full-Text Search Indexes

The `create_fts_index` and `drop_fts_index` options are only available when the `fts` extension is loaded. Their usage is documented on the Full-Text Search extension page.

Verification

Verification of External Operators Enable verification of external operators:

```
PRAGMA verify_external;
```

Disable verification of external operators:

```
PRAGMA disable_verify_external;
```

Verification of Round-Trip Capabilities Enable verification of round-trip capabilities for supported logical plans:

```
PRAGMA verify_serializer;
```

Disable verification of round-trip capabilities:

```
PRAGMA disable_verify_serializer;
```

Object Cache

Enable caching of objects for e.g., Parquet metadata:

```
PRAGMA enable_object_cache;
```

Disable caching of objects:

```
PRAGMA disable_object_cache;
```

Checkpointing

Compression During checkpointing, the existing column data + any new changes get compressed. There exist a couple of pragmas to influence which compression functions are considered.

Force Compression Prefer using this compression method over any other method if possible:

```
PRAGMA force_compression = 'bitpacking';
```

Disabled Compression Methods Avoid using any of the listed compression methods from the comma separated list:

```
PRAGMA disabled_compression_methods = 'fsst,rle';
```

Force Checkpoint When `CHECKPOINT` is called when no changes are made, force a checkpoint regardless:

```
PRAGMA force_checkpoint;
```

Checkpoint on Shutdown Run a `CHECKPOINT` on successful shutdown and delete the WAL, to leave only a single database file behind:

```
PRAGMA enable_checkpoint_on_shutdown;
```

Don't run a `CHECKPOINT` on shutdown:

```
PRAGMA disable_checkpoint_on_shutdown;
```

Temp Directory for Spilling Data to Disk

By default, DuckDB uses a temporary directory named `<database_file_name>.tmp{:.language-sql .highlight}` to spill to disk, located in the same directory as the database file. To change this, use:

```
SET temp_directory = '/path/to/temp_dir.tmp/';
```

Returning Errors as JSON

The `errors_as_json` option can be set to obtain error information in raw JSON format. For certain errors, extra information or decomposed information is provided for easier machine processing. For example:

```
SET errors_as_json = true;
```

Then, running a query that results in an error produces a JSON output:

```
SELECT * FROM nonexistent_tbl;
```

```
{
   "exception_type":"Catalog",
   "exception_message":"Table with name nonexistent_tbl does not exist!\nDid you mean
   \"temp.information_schema.tables\"?",
   "name":"nonexistent_tbl",
   "candidates":"temp.information_schema.tables",
   "position":"14",
   "type":"Table",
   "error_subtype":"MISSING_ENTRY"
}
```

IEEE Floating-Point Operation Semantics

DuckDB follows IEEE floating-point operation semantics. If you would like to turn this off, run:

```
SET ieee_floating_point_ops = false;
```

In this case, floating point division by zero (e.g., `1.0 / 0.0`, `0.0 / 0.0` and `-1.0 / 0.0`) will all return `NULL`.

Query Verification (for Development)

The following PRAGMAs are mostly used for development and internal testing.

Enable query verification:

```
PRAGMA enable_verification;
```

Disable query verification:

```
PRAGMA disable_verification;
```

Enable force parallel query processing:

```
PRAGMA verify_parallelism;
```

Disable force parallel query processing:

```
PRAGMA disable_verify_parallelism;
```

Block Sizes

When persisting a database to disk, DuckDB writes to a dedicated file containing a list of blocks holding the data. In the case of a file that only holds very little data, e.g., a small table, the default block size of 256 kB might not be ideal. Therefore, DuckDB's storage format supports different block sizes.

There are a few constraints on possible block size values.

- Must be a power of two.
- Must be greater or equal to 16384 (16 kB).
- Must be lesser or equal to 262144 (256 kB).

You can set the default block size for all new DuckDB files created by an instance like so:

```
SET default_block_size = '16384';
```

It is also possible to set the block size on a per-file basis, see ATTACH for details.

Secrets Manager

The **Secrets manager** provides a unified user interface for secrets across all backends that use them. Secrets can be scoped, so different storage prefixes can have different secrets, allowing for example to join data across organizations in a single query. Secrets can also be persisted, so that they do not need to be specified every time DuckDB is launched.

> **Warning.** Persistent secrets are stored in unencrypted binary format on the disk.

Types of Secrets

Secrets are typed, their type identifies which service they are for. Most secrets are not included in DuckDB by default; instead, they are registered by extensions. Currently, the following secret types are available:

Secret type	Service / protocol	Extension
`azure`	Azure Blob Storage	`azure`
`ducklake`	DuckLake	`ducklake`
`gcs`	Google Cloud Storage	`httpfs`
`http`	HTTP and HTTPS	`httpfs`
`huggingface`	Hugging Face	`httpfs`
`iceberg`	Iceberg REST Catalog	`httpfs`, `iceberg`
`mysql`	MySQL	`mysql`
`postgres`	PostgreSQL	`postgres`
`quack`	Quack	`quack`
`r2`	Cloudflare R2	`httpfs`
`s3`	AWS S3	`httpfs`

For each type, there are one or more "secret providers" that specify how the secret is created. Secrets can also have an optional scope, which is a file path prefix that the secret applies to. When fetching a secret for a path, the secret scopes are compared to the path, returning the matching secret for the path. In the case of multiple matching secrets, the longest prefix is chosen.

Creating a Secret

Secrets can be created using the `CREATE SECRET` SQL statement. Secrets can be **temporary** or **persistent**. Temporary secrets are used by default – and are stored in-memory for the life span of the DuckDB instance similar to how settings worked previously. Persistent secrets are stored in **unencrypted binary format** in the `~/.duckdb/stored_secrets` directory. On startup of DuckDB, persistent secrets are read from this directory and automatically loaded.

Secret Providers

To create a secret, a **Secret Provider** needs to be used. A Secret Provider is a mechanism through which a secret is generated. To illustrate this, for the `S3`, `GCS`, `R2`, and `AZURE` secret types, DuckDB currently supports two providers: `CONFIG` and `credential_chain`. The

`CONFIG` provider requires the user to pass all configuration information into the `CREATE SECRET`, whereas the `credential_chain` provider will automatically try to fetch credentials. When no Secret Provider is specified, the `CONFIG` provider is used. For more details on how to create secrets using different providers check out the respective pages on httpfs and azure.

Temporary Secrets

To create a temporary unscoped secret to access S3, we can now use the following:

```
CREATE SECRET my_secret (
    TYPE s3,
    KEY_ID 'my_secret_key',
    SECRET 'my_secret_value',
    REGION 'my_region'
);
```

Note that we implicitly use the default `CONFIG` secret provider here.

Persistent Secrets

In order to persist secrets between DuckDB database instances, we can now use the `CREATE PERSISTENT SECRET` command, e.g.:

```
CREATE PERSISTENT SECRET my_persistent_secret (
    TYPE s3,
    KEY_ID 'my_secret_key',
    SECRET 'my_secret_value'
);
```

By default, this will write the secret (unencrypted) to the `~/.duckdb/stored_secrets` directory. To change the secrets directory, issue:

```
SET secret_directory = 'path/to/my_secrets_dir';
```

Note that setting the value of the `home_directory` configuration option has no effect on the location of the secrets.

Deleting Secrets

Secrets can be deleted using the DROP SECRET statement, e.g.:

```
DROP PERSISTENT SECRET my_persistent_secret;
```

Creating Multiple Secrets for the Same Service Type

If two secrets exist for a service type, the scope can be used to decide which one should be used. For example:

```
CREATE SECRET secret1 (
    TYPE s3,
    KEY_ID 'my_secret_key1',
    SECRET 'my_secret_value1',
    SCOPE 's3://<my-bucket>'
);

CREATE SECRET secret2 (
    TYPE s3,
    KEY_ID 'my_secret_key2',
    SECRET 'my_secret_value2',
    SCOPE 's3://<my-other-bucket>'
);
```

Now, if the user queries something from `s3://<my-other-bucket>/something`, secret `secret2` will be chosen automatically for that request. To see which secret is being used, the `which_secret` scalar function can be used, which takes a path and a secret type as parameters:

```
FROM which_secret('s3://<my-other-bucket>/file.parquet', 's3');
```

Listing Secrets

Secrets can be listed using the built-in table-producing function, e.g., by using the `duckdb_secrets()` table function:

```
FROM duckdb_secrets();
```

Sensitive information will be redacted.

Extensions

Extensions

DuckDB has a flexible extension mechanism that allows for dynamically loading extensions. Extensions can enhance DuckDB's functionality by providing support for additional file formats, introducing new types, and domain-specific functionality.

> Extensions are loadable on all clients (e.g., Python and R). Extensions distributed via the Core and Community repositories are built and tested on macOS, Windows and Linux. All operating systems are supported for both the AMD64 and the ARM64 architectures.

Listing Extensions

To get a list of extensions, use the `duckdb_extensions` function:

```
SELECT extension_name, installed, description
FROM duckdb_extensions();
```

extension_name	installed	description
arrow	false	A zero-copy data integration between Apache Arrow and DuckDB
autocomplete	false	Adds support for autocomplete in the shell
...	...	...

This list will show which extensions are available, which extensions are installed, at which version, where it is installed, and more. The list includes most, but not all, available core extensions. For the full list, we maintain a list of core extensions.

> **Tip.** We provide an endpoint that serves weekly extension download statistics as JSON files: core extensions and community extensions.

Built-In Extensions

DuckDB's binary distribution comes standard with a few built-in extensions. They are statically linked into the binary and can be used as is. For example, to use the built-in `json` extension to read a JSON file:

```
SELECT *
FROM 'test.json';
```

To make the DuckDB distribution lightweight, only a few essential extensions are built-in, varying slightly per distribution. Which extension is built-in on which platform is documented in the list of core extensions.

Installing More Extensions

To make an extension that is not built-in available in DuckDB, two steps need to happen:

1. **Extension installation** is the process of downloading the extension binary and verifying its metadata. During installation, DuckDB stores the downloaded extension and some metadata in a local directory. From this directory DuckDB can then load the Extension whenever it needs to. This means that installation needs to happen only once.
2. **Extension loading** is the process of dynamically loading the binary into a DuckDB instance. DuckDB will search the local extension directory for the installed extension, then load it to make its features available. This means that every time DuckDB is restarted, all extensions that are used need to be (re)loaded

> Extension installation and loading are subject to a few limitations.

There are two main methods of making DuckDB perform the **installation** and **loading** steps for an installable extension: **explicitly** and through **autoloading**.

Explicit `INSTALL` and `LOAD`

In DuckDB extensions can also be explicitly installed and loaded. Both non-autoloadable and autoloadable extensions can be installed this way. To explicitly install and load an extension, DuckDB has the dedicated SQL statements `LOAD` and `INSTALL`. For example, to install and load the `spatial` extension, run:

```
INSTALL spatial;
LOAD spatial;
```

With these statements, DuckDB will ensure the `spatial` extension is installed (ignoring the `INSTALL` statement if it is already installed), then proceed to `LOAD` the spatial extension (again ignoring the statement if it is already loaded).

Extension Repository Optionally a repository can be provided where the extension should be installed from, by appending `FROM <repository>`{:.language-sql .highlight} to the `INSTALL` / `FORCE INSTALL` command. This repository can either be an alias, such as `community`, or it can be a direct URL, provided as a single-quoted string.

After installing/loading an extension, the `duckdb_extensions` function can be used to get more information.

Autoloading Extensions

For many of DuckDB's core extensions, explicitly loading and installing extensions is not necessary. DuckDB contains an autoloading mechanism which can install and load the core extensions as soon as they are used in a query. For example, when running:

```
SELECT *
FROM 'https://raw.githubusercontent.com/duckdb/duckdb-web/main/data/weather.csv';
```

DuckDB will automatically install and load the `httpfs` extension. No explicit `INSTALL` or `LOAD` statements are required.

Not all extensions can be autoloaded. This can have various reasons: some extensions make several changes to the running DuckDB instance, making autoloading technically not (yet) possible. For others, it is preferred to have users opt-in to the extension explicitly before use due to the way they modify behavior in DuckDB.

To see which extensions can be autoloaded, check the core extensions list.

Community Extensions

DuckDB supports installing third-party community extensions. For example, you can install the `tarfs` community extension via:

```
INSTALL tarfs FROM community;
```

Community extensions are contributed by community members but they are built, signed, and distributed in a centralized repository.

Updating Extensions

While built-in extensions are tied to a DuckDB release due to their nature of being built into the DuckDB binary, installable extensions can and do receive updates. To ensure all currently installed extensions are on the most recent version, call:

```
UPDATE EXTENSIONS;
```

For more details on extension versions, refer to the Extension Versioning page.

Developing Extensions

The same API that the core extensions use is available for developing extensions. This allows users to extend the functionality of DuckDB such that it suits their domain the best. A template for creating extensions is available in the `extension-template` repository. This template also holds some documentation on how to get started building your own extension.

Working with Extensions

See the installation instructions and the advanced installation methods page.

Installing Extensions

To install core DuckDB extensions, use the `INSTALL` command. For example:

```
INSTALL httpfs;
```

This installs the extension from the default repository (`core`).

Extension Repositories

By default, DuckDB extensions are installed from a single repository containing extensions built and signed by the core DuckDB team. This ensures the stability and security of the core set of extensions. These extensions live in the default `core` repository, which points to `http://extensions.duckdb.org`.

Besides the core repository, DuckDB also supports installing extensions from other repositories. For example, the `core_nightly` repository contains nightly builds for core extensions that are built for the latest stable release of DuckDB. This allows users to try out new features in extensions before they are officially published.

Installing Extensions from Different Repositories

To install extensions from the default repository (`core`), run:

```
INSTALL httpfs;
```

To explicitly install an extension from the core repository, run:

```
INSTALL httpfs FROM core;
-- or
INSTALL httpfs FROM 'http://extensions.duckdb.org';
```

To install an extension from the core nightly repository:

```
INSTALL spatial FROM core_nightly;
-- or
INSTALL spatial FROM 'http://nightly-extensions.duckdb.org';
```

To install an extension from a custom repository:

```
INSTALL <custom_extension> FROM 'https://my-custom-extension-repository';
```

Alternatively, the `custom_extension_repository` setting can be used to change the default repository used by DuckDB:

```
SET custom_extension_repository = 'http://nightly-extensions.duckdb.org';
```

DuckDB contains the following predefined repositories:

Alias	URL	Description
`core`	`http://extensions.duckdb.org`	DuckDB core extensions
`core_nightly`	`http://nightly-extensions.duckdb.org`	Nightly builds for `core`

Alias	URL	Description
`community`	`http://community-extensions.duckdb.org`	DuckDB community extensions
`local_build_debug`	`./build/debug/repository`	Repository created when building DuckDB from source in debug mode (for development)
`local_build_release`	`./build/release/repository`	Repository created when building DuckDB from source in release mode (for development)

Working with Multiple Repositories

When working with extensions from different repositories, especially mixing `core` and `core_nightly`, it is important to know the origins and version of the different extensions. For this reason, DuckDB keeps track of this in the extension installation metadata. For example:

```
INSTALL httpfs FROM core;
INSTALL aws FROM core_nightly;
SELECT extension_name, extension_version, installed_from, install_mode
FROM duckdb_extensions();
```

This outputs:

extensions_name	extensions_version	installed_from	install_mode
httpfs	62d61a417f	core	REPOSITORY
aws	42c78d3	core_nightly	REPOSITORY
…	…	…	…

Force Installing to Upgrade Extensions

When DuckDB installs an extension, it is copied to a local directory to be cached and avoid future network traffic. Any subsequent calls to `INSTALL <extension_name>{:.language-sql .highlight}` will use the local version instead of downloading the extension again. To force re-downloading the extension, run:

```
FORCE INSTALL extension_name;
```

Force installing can also be used to overwrite an extension with an extension of the same name from another repository,

For example, first, `spatial` is installed from the core repository:

```
INSTALL spatial;
```

Then, to overwrite this installation with the `spatial` extension from the `core_nightly` repository:

```
FORCE INSTALL spatial FROM core_nightly;
```

Switching between Repositories

To switch repositories for an extension, use the `FORCE INSTALL` command. For example, if you have installed `httpfs` from the `core_nightly` repository but would like to switch back to using `core`, run:

```
FORCE INSTALL httpfs FROM core;
```

Installing Extensions through Client APIs

For many clients, using SQL to load and install extensions is the preferred method. However, some clients have a dedicated API to install and load extensions. For example, the Python client, has dedicated `install_extension(name: str)` and `load_extension(name: str)` methods. For more details on a specific client API, refer to the Client API documentation

Installation Location

By default, extensions are installed under the user's home directory:

```
~/.duckdb/extensions/<duckdb_version>/<platform_name>/
```

For stable DuckDB releases, the <duckdb_version>{:.language-sql .highlight} will be equal to the version tag of that release. For nightly DuckDB builds, it will be equal to the short git hash of the build. So for example, the extensions for DuckDB version v0.10.3 on macOS ARM64 (Apple Silicon) are installed to `~/.duckdb/extensions/v0.10.3/osx_arm64/`. An example installation path for a nightly DuckDB build could be `~/.duckdb/extensions/fc2e4b26a6/linux_amd64`.

To change the default location where DuckDB stores its extensions, use the `extension_directory` configuration option:

```
SET extension_directory = '/path/to/your/extension/directory';
```

To specify multiple directories for loading extensions (e.g., for package managers or air-gapped environments), use the `extension_directories` option:

```
SET extension_directories = ['/usr/lib/duckdb/extensions', '/opt/duckdb/extensions'];
```

Note that setting the value of the `home_directory` configuration option has no effect on the location of the extensions.

Uninstalling Extensions

Currently, DuckDB does not provide a command to uninstall extensions. To uninstall an extension, navigate to the extension's Installation Location and remove its `.duckdb_extension` binary file: For example:

```
rm ~/.duckdb/extensions/v1.2.1/osx_arm64/excel.duckdb_extension
```

Sharing Extensions between Clients

The shared installation location allows extensions to be shared between the client APIs *of the same DuckDB version*, as long as they share the same `platform` or ABI. For example, if an extension is installed with version 1.2.1 of the CLI client on macOS, it is available from the Python, R, etc. client libraries provided that they have access to the user's home directory and use DuckDB version 1.2.1.

Limitations

DuckDB's extension mechanism has the following limitations:

- Extensions cannot be unloaded.
- Extensions cannot be reloaded. If you update extensions, restart the DuckDB process to use newer extensions.

Advanced Installation Methods

Downloading Extensions Directly from S3

Downloading an extension directly can be helpful when building a Lambda service or container that uses DuckDB. DuckDB extensions are stored in public S3 buckets, but the directory structure of those buckets is not searchable. As a result, a direct URL to the file must be used. To download an extension file directly, use the following format:

`http://extensions.duckdb.org/v<duckdb_version>/<platform_name>/<extension_name>.duckdb_extension.gz`

For example:

`http://extensions.duckdb.org/v1.5.4/windows_amd64/json.duckdb_extension.gz`

Installing an Extension from an Explicit Path

The `INSTALL` command can be used with the path to a `.duckdb_extension` file:

```
INSTALL 'path/to/httpfs.duckdb_extension';
```

Note that compressed `.duckdb_extension.gz` files need to be decompressed beforehand. It is also possible to specify remote paths.

Loading an Extension from an Explicit Path

`LOAD` can be used with the path to a `.duckdb_extension`. For example, if the file was available at the (relative) path `path/to/httpfs.duckdb_extension`, you can load it as follows:

```
LOAD 'path/to/httpfs.duckdb_extension';
```

This will skip any currently installed extensions and load the specified extension directly.

Note that using remote paths for compressed files is currently not possible.

Building and Installing Extensions from Source

For building and installing extensions from source, see the Building DuckDB guide.

Statically Linking Extensions

To statically link extensions, follow the developer documentation's "Using extension config files" section.

Extension Distribution

Platforms

Extension binaries are distributed for several platforms (see below). For platforms where packages for certain extensions are not available, users can build them from source and install the resulting binaries manually.

All official extensions are distributed for the following platforms.

Platform name	Operating system	Architecture	CPU types
`linux_amd64`	Linux	x86_64 (AMD64)	
`linux_arm64`	Linux	AArch64 (ARM64)	AWS Graviton, Snapdragon, etc.
`osx_amd64`	macOS	x86_64 (AMD64)	Intel
`osx_arm64`	macOS	AArch64 (ARM64)	Apple Silicon M1, M2, etc.
`windows_amd64`	Windows	x86_64 (AMD64)	Intel, AMD, etc.
`windows_arm64`	Windows	AArch64 (ARM64)	Copilot+ PC with Qualcomm CPU

Some extensions are distributed for the following platforms:

- `windows_amd64_mingw`
- `wasm_eh` and `wasm_mvp` (see DuckDB-Wasm's extensions)

For platforms outside the ones listed above, we do not officially distribute extensions (e.g., `linux_arm64_android`).

Extensions Signing

Signed Extensions

Extensions can be signed with a cryptographic key. By default, DuckDB uses its built-in public keys to verify the integrity of extensions before loading them. All core and community extensions are signed by the DuckDB team.

Signing the extension simplifies their distribution, this is why they can be distributed over HTTP without the need for HTTPS, which itself is supported through an extension (`httpfs`).

Unsigned Extensions

> **Warning.** Only load unsigned extensions from sources you trust. Avoid loading unsigned extensions over HTTP. Consult the Securing DuckDB page for guidelines on how to set up DuckDB in a secure manner.

If you wish to load your own extensions or extensions from third-parties you will need to enable the `allow_unsigned_extensions` flag. To load unsigned extensions using the CLI client, pass the `-unsigned` flag to it on startup:

```
duckdb -unsigned
```

Now any extension can be loaded, signed or not:

```
LOAD './some/local/ext.duckdb_extension';
```

For client APIs, the `allow_unsigned_extensions` database configuration options needs to be set, see the respective Client API docs. For example, for the Python client, see the Loading and Installing Extensions section in the Python API documentation.

Binary Compatibility

To avoid binary compatibility issues, the binary extensions distributed by DuckDB are tied both to a specific DuckDB version and a platform. This means that DuckDB can automatically detect binary compatibility between it and a loadable extension. When trying to load an extension that was compiled for a different version or platform, DuckDB will throw an error and refuse to load the extension.

Creating a Custom Repository

You can create a custom DuckDB extension repository. A DuckDB repository is an HTTP, HTTPS, S3, or local file based directory that serves the extensions files in a specific structure. This structure is described in the "Downloading Extensions Directly from S3" section, and is the same for local paths and remote servers, for example:

```
base_repository_path_or_url
└── v1.0.0
    └── osx_arm64
        ├── autocomplete.duckdb_extension
        ├── httpfs.duckdb_extension
        ├── icu.duckdb_extension
        ├── inet.duckdb_extension
        ├── json.duckdb_extension
        ├── parquet.duckdb_extension
        ├── tpcds.duckdb_extension
        ├── tpcds.duckdb_extension
        └── tpch.duckdb_extension
```

See the `extension-template` repository for all necessary code and scripts to set up a repository.

When installing an extension from a custom repository, DuckDB will search for both a gzipped and non-gzipped version. For example:

```
INSTALL icu FROM '<custom_repository>';
```

The execution of this statement will first look for `icu.duckdb_extension.gz`, then `icu.duckdb_extension` in the repository's directory structure.

If the custom repository is served over HTTPS or S3, the `httpfs` extension is required. DuckDB will attempt to autoload the `httpfs` extension when an installation over HTTPS or S3 is attempted.

Versioning of Extensions

Extension Versioning

Most software has some sort of version number. Version numbers serve a few important goals:

- Tie a binary to a specific state of the source code
- Allow determining the expected feature set
- Allow determining the state of the APIs
- Allow efficient processing of bug reports (e.g., bug `#1337` was introduced in version `v3.4.5`)
- Allow determining chronological order of releases (e.g., version `v1.2.3` is older than `v1.2.4`)
- Give an indication of expected stability (e.g., `v0.0.1` is likely not very stable, whereas `v13.11.0` probably is stable)

Just like DuckDB itself, DuckDB extensions have their own version number. To ensure consistent semantics of these version numbers across the various extensions, DuckDB's Core Extensions use a versioning scheme that prescribes how extensions should be versioned. The versioning scheme for Core Extensions is made up of 3 different stability levels: **unstable**, **pre-release**, and **stable**. Let's go over each of the 3 levels and describe their format:

Unstable Extensions

Unstable extensions are extensions that can't (or don't want to) give any guarantees regarding their current stability, or their goals of becoming stable. Unstable extensions are tagged with the **short git hash** of the extension.

For example, at the time of writing this, the version of the `vss` extension is an unstable extension of version `690bfc5`.

What to expect from an extension that has a version number in the **unstable** format?

- The state of the source code of the extension can be found by looking up the hash in the extension repository
- Functionality may change or be removed completely with every release
- This extension's API could change with every release
- This extension may not follow a structured release cycle, new (breaking) versions can be pushed at any time

Pre-Release Extensions

Pre-release extensions are the next step up from Unstable extensions. They are tagged with version in the **SemVer** format, more specifically, those in the `v0.y.z` format. In semantic versioning, versions starting with `v0` have a special meaning: they indicate that the more strict semantics of regular (`>v1.0.0`) versions do not yet apply. It basically means that an extension is working towards becoming a stable extension, but is not quite there yet.

For example, at the time of writing this, the version of the `delta` extension is a pre-release extension of version `v0.1.0`.

What to expect from an extension that has a version number in the **pre-release** format?

- The extension is compiled from the source code corresponding to the tag.
- Semantic Versioning semantics apply. See the Semantic Versioning specification for details.
- The extension follows a release cycle where new features are tested in nightly builds before being grouped into a release and pushed to the `core` repository.
- Release notes describing what has been added each release should be available to make it easy to understand the difference between versions.

Stable Extensions

Stable extensions are the final step of extension stability. This is denoted by using a **stable SemVer** of format `vx.y.z` where `x>0`.

For example, at the time of writing this, the version of the `parquet` extension is a stable extension of version `v1.0.0`.

What to expect from an extension that has a version number in the **stable** format? Essentially the same as pre-release extensions, but now the more strict SemVer semantics apply: the API of the extension should now be stable and will only change in backwards incompatible ways when the major version is bumped. See the SemVer specification for details

Release Cycle of Pre-Release and Stable Core Extensions

In general for extensions the release cycle depends on their stability level. **unstable** extensions are often in sync with DuckDB's release cycle, but may also be quietly updated between DuckDB releases. **pre-release** and **stable** extensions follow their own release cycle. These may or may not coincide with DuckDB releases. To find out more about the release cycle of a specific extension, refer to the documentation or GitHub page of the respective extension. Generally, **pre-release** and **stable** extensions will document their releases as GitHub releases, an example of which you can see in the `delta` extension.

Finally, there is a small exception: All in-tree extensions simply follow DuckDB's release cycle.

Nightly Builds

Just like DuckDB itself, DuckDB's core extensions have nightly or dev builds that can be used to try out features before they are officially released. This can be useful when your workflow depends on a new feature, or when you need to confirm that your stack is compatible with the upcoming version.

Nightly builds for extensions are slightly complicated due to the fact that currently DuckDB extensions binaries are tightly bound to a single DuckDB version. Because of this tight connection, there is a potential risk for a combinatorial explosion. Therefore, not all combinations of nightly extension build and nightly DuckDB build are available.

In general, there are 2 ways of using nightly builds: using a nightly DuckDB build and using a stable DuckDB build. Let's go over the differences between the two:

From Stable DuckDB

In most cases, users will be interested in a nightly build of a specific extension, but don't necessarily want to switch to using the nightly build of DuckDB itself. This allows using a specific bleeding-edge feature while limiting the exposure to unstable code.

To achieve this, Core Extensions tend to regularly push builds to the `core_nightly` repository. Let's look at an example:

First we install a **stable DuckDB build**.

Then we can install and load a **nightly** extension like this:

```
INSTALL aws FROM core_nightly;
LOAD aws;
```

In this example we are using the latest **nightly** build of the aws extension with the latest **stable** version of DuckDB.

From Nightly DuckDB

When DuckDB CI produces a nightly binary of DuckDB itself, the binaries are distributed with a set of extensions that are pinned at a specific version. This extension version will be tested for that specific build of DuckDB, but might not be the latest dev build. Let's look at an example:

First, we install a **nightly DuckDB build**. Then, we can install and load the `aws` extension as expected:

```
INSTALL aws;
LOAD aws;
```

Updating Extensions

DuckDB has a dedicated statement that will automatically update all extensions to their latest version. The output will give the user information on which extensions were updated to/from which version. For example:

```
UPDATE EXTENSIONS;
```

extension_name	repository	update_result	previous_version	current_version
httpfs	core	NO_UPDATE_AVAILABLE	70fd6a8a24	70fd6a8a24
delta	core	UPDATED	d9e5cc1	04c61e4
azure	core	NO_UPDATE_AVAILABLE	49b63dc	49b63dc
aws	core_nightly	NO_UPDATE_AVAILABLE	42c78d3	42c78d3

Note that DuckDB will look for updates in the source repository for each extension. So if an extension was installed from `core_nightly`, it will be updated with the latest nightly build.

The update statement can also be provided with a list of specific extensions to update:

```
UPDATE EXTENSIONS (httpfs, azure);
```

extension_name	repository	update_result	previous_version	current_version
httpfs	core	NO_UPDATE_AVAILABLE	70fd6a8a24	70fd6a8a24
azure	core	NO_UPDATE_AVAILABLE	49b63dc	49b63dc

Target DuckDB Version

Currently, when extensions are compiled, they are tied to a specific version of DuckDB. What this means is that, for example, an extension binary compiled for version 0.10.3 does not work for version 1.0.0. In most cases, this will not cause any issues and is fully transparent; DuckDB will automatically ensure it installs the correct binary for its version. For extension developers, this means that they must ensure that new binaries are created whenever a new version of DuckDB is released. However, note that DuckDB provides an extension template that makes this fairly simple.

In-Tree vs. Out-of-Tree

Originally, DuckDB extensions lived exclusively in the DuckDB main repository, `github.com/duckdb/duckdb`. These extensions are called in-tree. Later, the concept of out-of-tree extensions was added, where extensions were separated into their own repository, which we call out-of-tree.

While from a user's perspective, there are generally no noticeable differences, there are some minor differences related to versioning:

- in-tree extensions use the version of DuckDB instead of having their own version
- in-tree extensions do not have dedicated release notes, their changes are reflected in the regular DuckDB release notes
- core out-of tree extensions tend to live in repositories named `github.com/duckdb/duckdb-<extension_name>`{:.language-sql .highlight} but the name may vary. See the full list of core extensions for details.

Troubleshooting of Extensions

You might be visiting this page directed via a DuckDB error message, similar to:

```
INSTALL non_existing;
```

```
HTTP Error:
Failed to download extension "non_existing" at URL "http://extensions.duckdb.org/v1.4.0/osx_arm64/non_
existing.duckdb_extension.gz" (HTTP 404)

Candidate extensions: "inet", "encodings", "core_functions", "sqlite_scanner", "postgres_scanner"
For more info, visit
https://duckdb.org/docs/stable/extensions/troubleshooting?version=v1.4.0&platform=osx_
arm64&extension=non_existing
```

There are multiple scenarios for which an extension might not be available in a given extension repository at a given time:

- the extension has not been uploaded yet, here some delay after a given release date might be expected. Consider checking the issues at duckdb/duckdb or duckdb/community-extensions, or creating one yourself.
- the extension is available, but in a different repository, try for example `INSTALL <name> FROM core;`{:.language-sql .highlight} or `INSTALL <name> FROM community;`{:.language-sql .highlight} or `INSTALL <name> FROM core_nightly;`{:.language-sql .highlight} (see the Installing Extensions page).
- networking issues, so extension exists at the endpoint but it's not reachable from your local DuckDB. Here you can try visiting the given URL via a browser directly pasting the link from the error message in the search bar.

If you are on a development version of DuckDB, that is any version for which `PRAGMA version` returns a `library_version` not starting with a `v`, then extensions might not be available anymore on the default extension repository.

When in doubt, consider raising an issue in duckdb/duckdb.

Manual Process to Download Extensions via the Browser

To check if an extension is available, consider trying to download the relevant extension resource, for example via your browser visiting https://extensions.duckdb.org/v1.4.4/osx_arm64/spatial.duckdb_extension.gz or any other link that has been provided. Note that `http://` has been deprecated in favor of `https://`.

If successful, this will download and unpack the extension to the default `Downloads` folder, so that from SQL you can run:

```
INSTALL '~/Downloads/spatial.duckdb_extension';
-- or
FORCE INSTALL '~/Downloads/spatial.duckdb_extension';
```

and after this command the extension will be regularly installed.

Core Extensions

Core Extensions

List of Core Extensions

Name	Description	MaintainerSupport tier	Aliases
autocomplete	Adds support for autocomplete in the shell	DuckDB team	
avro	Add support for reading Avro files	DuckDB team	
aws	Provides features that depend on the AWS SDK	DuckDB team	
azure	Adds a filesystem abstraction for Azure blob storage to DuckDB	DuckDB team	
delta	Adds support for Delta Lake	DuckDB team	
ducklake	Adds support for DuckLake	DuckDB team	
encodings	Adds support for encodings available in the ICU data repository	DuckDB team	
excel	Adds support for reading and writing Excel files	DuckDB team	
fts	Adds support for full-text search indexes	DuckDB team	
httpfs	Adds support for reading/writing files over an HTTP(S) or S3 connection	DuckDB team	http, https, s3
iceberg	Adds support for Apache Iceberg	DuckDB team	
icu	Adds support for time zones and collations using the ICU library	DuckDB team	
inet	Adds support for IP-related data types and functions	DuckDB team	
json	Adds support for JSON operations	DuckDB team	
lance	Adds support to read and write Lance tables	Third party	
motherduck	Allows connecting to MotherDuck	Third party	md
mysql	Adds support for reading from and writing to a MySQL database	DuckDB team	mysql_scanner
odbc	Adds support for accessing remote databases over ODBC drivers	DuckDB team	odbc_scanner

Name	Description	MaintainerSupport tier	Aliases
parquet	Adds support for reading and writing Parquet files	DuckDB team	
postgres	Adds support for reading from and writing to a PostgreSQL database	DuckDB team	postgres_scanner
quack	Adds the DuckDB-Quack protocol for remote access	DuckDB team	
spatial	Adds support for working with geospatial data and functions	DuckDB team	
sqlite	Adds support for reading from and writing to SQLite database files	DuckDB team	sqlite_scanner, sqlite3
tpcds	Adds TPC-DS data generation and query support	DuckDB team	
tpch	Adds TPC-H data generation and query support	DuckDB team	
unity_catalog	Adds support for connecting to Unity Catalog	DuckDB team	uc_catalog
ui	Adds local UI for DuckDB	Third party	
vortex	Adds support for reading and writing Vortex files	Third party	
vss	Adds support for vector similarity search queries	DuckDB team	

The **Maintainer** column denotes whether the extension is maintained by the DuckDB team or by a third party. For the extensions maintained by the DuckDB team, the **Support tier** column denotes the extension's support status. *Primary extensions* are covered by community support. *Secondary extensions* are supported on a best-effort basis. That said, they still receive frequent bugfixes/updates and are shipped with new DuckDB releases.

AutoComplete Extension

The `autocomplete` extension adds support for autocomplete in the CLI client. The extension is shipped by default with the CLI client.

Behavior

For the behavior of the `autocomplete` extension, see the documentation of the CLI client.

Functions

Function	Description
`sql_auto_complete(query_string)`	Attempts autocompletion on the given `query_string`.

Example

```
SELECT *
FROM sql_auto_complete('SEL');
```

Returns:

suggestion	suggestion_start
SELECT	0
DELETE	0
INSERT	0
CALL	0
LOAD	0
CALL	0
ALTER	0
BEGIN	0
EXPORT	0
CREATE	0
PREPARE	0
EXECUTE	0
EXPLAIN	0
ROLLBACK	0
DESCRIBE	0
SUMMARIZE	0
CHECKPOINT	0

suggestion	suggestion_start
DEALLOCATE	0
UPDATE	0
DROP	0

Avro Extension

The `avro` extension enables DuckDB to read Apache Avro files.

> The `avro` extension was released as a community extension in late 2024 and became a core extension in early 2025.

The `read_avro` Function

The extension adds a single DuckDB function, `read_avro`. This function can be used like so:

```
FROM read_avro('<some_file>.avro');
```

This function will expose the contents of the Avro file as a DuckDB table. You can then use any arbitrary SQL constructs to further transform this table.

File IO

The `read_avro` function is integrated into DuckDB's file system abstraction, meaning you can read Avro files directly from, e.g., HTTP or S3 sources. For example:

```
FROM read_avro('https://blobs.duckdb.org/data/userdata1.avro');
FROM read_avro('s3://<your-bucket>/<some_file>.avro');
```

should ”just” work.

You can also *glob* multiple files in a single read call or pass a list of files to the functions:

```
FROM read_avro('some_file_*.avro');
FROM read_avro(['some_file_1.avro', 'some_file_2.avro']);
```

If the filenames somehow contain valuable information (as is unfortunately all-too-common), you can pass the `filename` argument to `read_avro`:

```
FROM read_avro('some_file_*.avro', filename=true);
```

This will result in an additional column in the result set that contains the actual filename of the Avro file.

Schema Conversion

This extension automatically translates the Avro Schema to the DuckDB schema. *All* Avro types can be translated, except for *recursive type definitions*, which DuckDB does not support.

The type mapping is very straightforward except for Avro's ”unique” way of handling `NULL`. Unlike other systems, Avro does not treat `NULL` as a possible value in a range of e.g. `INTEGER` but instead represents `NULL` as a union of the actual type with a special `NULL` type. This is different to DuckDB, where any value can be `NULL`. Of course DuckDB also supports `UNION` types, but this would be quite cumbersome to work with.

This extension *simplifies* the Avro schema where possible: An Avro union of any type and the special null type is simplified to just the non-null type. For example, an Avro record of the union type `["int","null"]` becomes a DuckDB `INTEGER`, which just happens to be `NULL` sometimes. Similarly, an Avro union that contains only a single type is converted to the type it contains. For example, an Avro record of the union type `["int"]` also becomes a DuckDB `INTEGER`.

The extension also ”flattens” the Avro schema. Avro defines tables as root-level ”record” fields, which are the same as DuckDB `STRUCT` fields. For more convenient handling, this extension turns the entries of a single top-level record into top-level columns.

Implementation

Internally, this extension uses the ”official” Apache Avro C API, albeit with some minor patching to allow reading of Avro files from memory.

Limitations and Future Plans

- This extension currently does not make use of **parallelism** when reading either a single (large) Avro file or when reading a list of files. Adding support for parallelism in the latter case is on the roadmap.
- There is currently no support for either projection or filter **pushdown**, but this is also planned at a later stage.
- There is currently no support for the Wasm or the Windows-MinGW builds of DuckDB due to issues with the Avro library dependency (sigh again). We plan to fix this eventually.
- As mentioned above, DuckDB cannot express recursive type definitions that Avro has, this is unlikely to ever change.
- There is no support to allow users to provide a separate Avro schema file. This is unlikely to change, all Avro files we have seen so far had their schema embedded.
- There is currently no support for the `union_by_name` flag that other readers in DuckDB support. This is planned for the future.

AWS Extension

The aws extension adds functionality, e.g., authentication, on top of the `httpfs` extension's S3 capabilities, using the AWS SDK.

Installing and Loading

The aws extension will be transparently autoloaded on first use from the official extension repository. If you would like to install and load it manually, run:

```
INSTALL aws;
LOAD aws;
```

> In most cases, the aws extension works in conjunction with the `httpfs` extension.

Configuration and Authentication

The preferred way to configure and authenticate to AWS S3 endpoints is to use secrets.

`config` Provider

The default provider, `config` (i.e., user-configured), allows access to the S3 bucket by manually providing a key. For example:

```
CREATE OR REPLACE SECRET secret (
    TYPE s3,
    PROVIDER config,
    KEY_ID '<AKIAIOSFODNN7EXAMPLE>',
    SECRET '<wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY>',
    REGION '<us-east-1>'
);
```

> **Tip.** If you get an IO Error (`Connection error for HTTP HEAD`), configure the endpoint explicitly via `ENDPOINT 's3.<your-region>.amazonaws.com'`{:.language-sql .highlight}.

Now, to query using the above secret, simply query any `s3://` prefixed file:

```
SELECT *
FROM 's3://<your-bucket>/<your_file>.parquet';
```

`credential_chain` Provider

The `credential_chain` provider allows automatically fetching credentials using mechanisms provided by the AWS SDK. For example, to use the AWS SDK default provider:

```
CREATE OR REPLACE SECRET secret (
    TYPE s3,
    PROVIDER credential_chain
);
```

Again, to query a file using the above secret, simply query any `s3://` prefixed file.

DuckDB also allows specifying a specific chain using the `CHAIN` keyword. This takes a semicolon-separated list (`a;b;c`) of providers that will be tried in order. For example:

```
CREATE OR REPLACE SECRET secret (
    TYPE s3,
    PROVIDER credential_chain,
    CHAIN 'env;config'
);
```

The possible values for `CHAIN` are the following:

- `config`
- `sts`
- `sso`
- `env`
- `instance`
- `process`

The `credential_chain` provider also allows overriding the automatically fetched config. For example, to automatically load credentials, and then override the region, run:

```
CREATE OR REPLACE SECRET secret (
    TYPE s3,
    PROVIDER credential_chain,
    CHAIN config,
    REGION '<eu-west-1>'
);
```

Validation

The AWS `credential_chain` provider will look for any required credentials during `CREATE SECRET` time, failing if absent/unavailable.

This behavior may be configured via the `VALIDATION` option as follows:

```
CREATE OR REPLACE SECRET secret (
    TYPE s3,
    PROVIDER credential_chain,
    VALIDATION 'exists'
);
```

Two validation modes are supported:

- `exists` (default) requires present credentials.
- none allows `CREATE SECRET` to succeed for `credential_chains` with no available credentials.

> `VALIDATION 'exists'` validates only the **presence** of a credential, **not its operational readiness**. Thus, no attempt is made to convert into an access token, or perform a read, write, etc.

Auto-Refresh

Some AWS endpoints require periodic refreshing of the credentials. This can be specified with the `REFRESH auto` option:

```
CREATE SECRET env_test (
    TYPE s3,
    PROVIDER credential_chain,
    REFRESH auto
);
```

Legacy Features

> **Deprecated.** The `load_aws_credentials` function is deprecated.

Prior to version 0.10.0, DuckDB did not have a Secrets manager, to load the credentials automatically, the AWS extension provided a special function to load the AWS credentials in the legacy authentication method.

Function	Type	Description
`load_aws_credentials`	PRAGMA function	Loads the AWS credentials through the AWS Default Credentials Provider Chain

Load AWS Credentials (Legacy)

To load the AWS credentials, run:

```
CALL load_aws_credentials();
```

loaded_access_key_id	loaded_secret_access_key	loaded_session_token	loaded_region
AKIAIOSFODNN7EXAMPLE	`<redacted>`	NULL	us-east-2

The function takes a string parameter to specify a specific profile:

```
CALL load_aws_credentials('minio-testing-2');
```

loaded_access_key_id	loaded_secret_access_key	loaded_session_token	loaded_region
minio_duckdb_user_2	`<redacted>`	NULL	NULL

There are several parameters to tweak the behavior of the call:

```
CALL load_aws_credentials('minio-testing-2', set_region = false, redact_secret = false);
```

loaded_access_key_id	loaded_secret_access_key	loaded_session_token	loaded_region
minio_duckdb_user_2	minio_duckdb_user_password_2	NULL	NULL

SSO Auth Implementation

Note: none of these methods are able to authenticate when using `aws sso login` to authenticate and get the parameters. A simple workaround is to use AWS' `boto3` to retrieve the credentials and pass this into the DuckDB config. Note: the `SESSION_TOKEN` is required for authentication which is not mentioned above.

```
import boto3
import duckdb

session = boto3.Session(profile_name="YOUR_AWS_PROFILE")
credentials = session.get_credentials()

conn = duckdb.connect()
conn.query("""
```

```
    INSTALL aws;
    LOAD aws;
    INSTALL httpfs;
    LOAD httpfs;
    CREATE OR REPLACE SECRET secret (
        TYPE S3,
        PROVIDER config,
        KEY_ID 'crendentials.access_key',
        SECRET '{credentials.secret_key}',
        SESSION_TOKEN '{credentials.token}',
        REGION '{session.region_name}'
    );
""")
```

Azure Extension

The `azure` extension is a loadable extension that adds a filesystem abstraction for Azure Blob Storage to DuckDB, enabling both reading and writing data.

Installing and Loading

The `azure` extension will be transparently autoloaded on first use from the official extension repository. If you would like to install and load it manually, run:

```
INSTALL azure;
LOAD azure;
```

Usage

Once the authentication is set up, you can query Azure storage as follows:

Azure Blob Storage

Allowed URI schemes: `az` or `azure`

```
SELECT count(*)
FROM 'az://<my_container>/<path>/<my_file>.<parquet_or_csv>';
```

Globs are also supported:

```
SELECT *
FROM 'az://<my_container>/<path>/*.csv';
```

```
SELECT *
FROM 'az://<my_container>/<path>/**';
```

Or with a fully qualified path syntax:

```
SELECT count(*)
FROM 'az://<my_storage_account>.blob.core.windows.net/<my_container>/<path>/<my_file>.<parquet_or_csv>';
```

```
SELECT *
FROM 'az://<my_storage_account>.blob.core.windows.net/<my_container>/<path>/*.csv';
```

Azure Data Lake Storage (ADLS)

Allowed URI schemes: `abfss`

```
SELECT count(*)
FROM 'abfss://<my_filesystem>/<path>/<my_file>.<parquet_or_csv>';
```

Globs are also supported:

```
SELECT *
FROM 'abfss://<my_filesystem>/<path>/*.csv';
```

```
SELECT *
FROM 'abfss://<my_filesystem>/<path>/**';
```

Or with a fully qualified path syntax:

```
SELECT count(*)
FROM 'abfss://<my_storage_account>.dfs.core.windows.net/<my_filesystem>/<path>/<my_file>.<parquet_or_
csv>';
```

```
SELECT *
FROM 'abfss://<my_storage_account>.dfs.core.windows.net/<my_filesystem>/<path>/*.csv';
```

Writing to Azure Blob Storage

You can write data directly to Azure Blob or ADLSv2 Storage using the COPY statement.

```
-- Write query results to a Parquet file on Blob Storage
COPY (SELECT * FROM my_table)
TO 'az://<my_container>/<path>/output.parquet';
```

```
-- Write a table to a CSV file on ADLSv2 Storage
COPY my_table
TO 'abfss://<my_container>/<path>/output.csv';
```

You can also use fully qualified paths:

```
COPY my_table
TO 'az://<my_storage_account>.blob.core.windows.net/<my_container>/<path>/output.parquet';
```

Configuration

Use the following configuration options to control how the extension reads remote files:

Name	Description	Type	Default
`azure_http_stats`	Include HTTP info from Azure Storage in the `EXPLAIN ANALYZE` statement.	`BOOLEAN`	`false`
`azure_read_transfer_concurrency`	Maximum number of threads the Azure client can use for a single parallel read. If `azure_read_transfer_chunk_size` is less than `azure_read_buffer_size` then setting this > 1 will allow the Azure client to do concurrent requests to fill the buffer.	`BIGINT`	`5`
`azure_read_transfer_chunk_size`	Maximum size in bytes that the Azure client will read in a single request. It is recommended that this is a factor of `azure_read_buffer_size`.	`BIGINT`	`1024*1024`

Name	Description	Type	Default
`azure_read_buffer_size`	Size of the read buffer. It is recommended that this is evenly divisible by `azure_read_transfer_chunk_size`.	`UBIGINT`	`1024*1024`
`azure_transport_option_type`	Underlying adapter to use in the Azure SDK. Valid values are: `default` or `curl`.	`VARCHAR`	`default`
`azure_context_caching`	Enable/disable the caching of the underlying Azure SDK HTTP connection in the DuckDB connection context when performing queries. If you suspect that this is causing some side effect, you can try to disable it by setting it to false (not recommended).	`BOOLEAN`	`true`

> Setting `azure_transport_option_type` explicitly to `curl` will have the following effect:
>
> - On Linux, this may solve certificate issue (`Error: Invalid Error: Fail to get a new connection for: https://storage_account_name.blob.core.windows.net/. Problem with the SSL CA cert (path? access rights?)`) because when specifying the extension will try to find the bundle certificate in various paths (that is not done by *curl* by default and might be wrong due to static linking).
> - On Windows, this replaces the default adapter (*WinHTTP*) allowing you to use all *curl* capabilities (for example using a socks proxies).
> - On all operating systems, it will honor the following environment variables:
>   - `CURL_CA_INFO`: Path to a PEM encoded file containing the certificate authorities sent to libcurl. Note that this option is known to only work on Linux and might throw if set on other platforms.
>   - `CURL_CA_PATH`: Path to a directory which holds PEM encoded files, containing the certificate authorities sent to libcurl.

Example:

```
SET azure_http_stats = false;
SET azure_read_transfer_concurrency = 5;
SET azure_read_transfer_chunk_size = 1_048_576;
SET azure_read_buffer_size = 1_048_576;
```

Authentication

The Azure extension has two ways to configure the authentication. The preferred way is to use Secrets.

Authentication with Secret

Multiple Secret Providers are available for the Azure extension:

- If you need to define different secrets for different storage accounts, use the SCOPE configuration. Note that the SCOPE requires a trailing slash (`SCOPE 'azure://some_container/'`).
- If you use fully qualified path then the `ACCOUNT_NAME` attribute is optional.

`CONFIG` Provider The default provider, `CONFIG` (i.e., user-configured), allows access to the storage account using a connection string or anonymously. For example:

```
CREATE SECRET secret1 (
    TYPE azure,
    CONNECTION_STRING '<value>'
);
```

If you do not use authentication, you still need to specify the storage account name. For example:

```
CREATE SECRET secret2 (
    TYPE azure,
    PROVIDER config,
    ACCOUNT_NAME '<storage_account_name>'
);
```

The default `PROVIDER` is `CONFIG`.

`credential_chain` Provider The `credential_chain` provider allows connecting using credentials automatically fetched by the Azure SDK via the Azure credential chain. By default, the `DefaultAzureCredential` chain used, which tries credentials according to the order specified by the Azure documentation. For example:

```
CREATE SECRET secret3 (
    TYPE azure,
    PROVIDER credential_chain,
    ACCOUNT_NAME '<storage_account_name>'
);
```

DuckDB also allows specifying a specific chain using the `CHAIN` keyword. This takes a semicolon-separated list (`a;b;c`) of providers that will be tried in order. For example:

```
CREATE SECRET secret4 (
    TYPE azure,
    PROVIDER credential_chain,
    CHAIN 'cli;env',
    ACCOUNT_NAME '<storage_account_name>'
);
```

The possible values are the following: `cli`; `managed_identity`; `workload_identity`; `env`; `default`;

If no explicit `CHAIN` is provided, the default one will be `default`

Managed Identity Managed Identity (MI) can be used gracefully and automatically via the `credential_chain`. In typical cases where the executor has a single MI available, no configuration is needed.

If your execution environment has multiple Identities, use the `MANAGED_IDENTITY` provider and specify which identity to use. This provider allows identity specification via one of `CLIENT_ID`, `OBJECT_ID` or `RESOURCE_ID`, e.g.:

```
CREATE SECRET secret1 (
    TYPE AZURE,
    PROVIDER MANAGED_IDENTITY,
    ACCOUNT_NAME '<storage account name>',
    CLIENT_ID '<used-assigned managed identity client id>'
);
```

The provider may be used without specifying an ID; if only a single ID is available this provider will function identically to the `credential_chain` provider, and use the single available ID. If multiple IDs are available, behavior is undefined (or more specifically, defined by the Azure SDK) – therefore we recommend explicit Identity setting in this situation.

`SERVICE_PRINCIPAL` Provider The `SERVICE_PRINCIPAL` provider allows connecting using a Azure Service Principal (SPN).

Either with a secret:

```
CREATE SECRET azure_spn (
    TYPE azure,
    PROVIDER service_principal,
    TENANT_ID '<tenant_id>',
    CLIENT_ID '<client_id>',
    CLIENT_SECRET '<client_secret>',
    ACCOUNT_NAME '<storage_account_name>'
);
```

Or with a certificate:

```
CREATE SECRET azure_spn_cert (
    TYPE azure,
    PROVIDER service_principal,
    TENANT_ID '<tenant_id>',
    CLIENT_ID '<client_id>',
    CLIENT_CERTIFICATE_PATH '<client_cert_path>',
    ACCOUNT_NAME '<storage_account_name>'
);
```

Configuring a Proxy To configure proxy information when using secrets, you can add `HTTP_PROXY`, `PROXY_USER_NAME` and `PROXY_PASSWORD` in the secret definition. For example:

```
CREATE SECRET secret5 (
    TYPE azure,
    CONNECTION_STRING '<value>',
    HTTP_PROXY 'http://localhost:3128',
    PROXY_USER_NAME 'john',
    PROXY_PASSWORD 'doe'
);
```

> - When using secrets, the `HTTP_PROXY` environment variable will still be honored except if you provide an explicit value for it.
> - When using secrets, the `SET` variable of the *Authentication with variables* session will be ignored.
> - For the Azure `credential_chain` provider, the actual token is fetched at query time, not when the secret is created.

Authentication with Variables (Deprecated)

```
SET variable_name = variable_value;
```

Where `variable_name` can be one of the following:

Name	Description	Type	Default
`azure_storage_connection_string`	Azure connection string, used for authenticating and configuring Azure requests.	`STRING`	-
`azure_account_name`	Azure account name, when set, the extension will attempt to automatically detect credentials (not used if you pass the connection string).	`STRING`	-

Name	Description	Type	Default
`azure_endpoint`	Override the Azure endpoint for when the Azure credential providers are used.	`STRING`	`blob.core.windows.net`
`azure_credential_chain`	Ordered list of Azure credential providers, in string format separated by `;`. For example: `'cli;managed_identity;env'`. See the list of possible values in the `credential_chain` provider section. Not used if you pass the connection string.	`STRING`	-
`azure_http_proxy`	Proxy to use when login & performing request to Azure.	`STRING`	HTTP_PROXY environment variable (if set).
`azure_proxy_user_name`	HTTP proxy username if needed.	`STRING`	-
`azure_proxy_password`	HTTP proxy password if needed.	`STRING`	-

Additional Information

Logging

The Azure extension relies on the Azure SDK to connect to Azure Blob storage and supports printing the SDK logs to the console. To control the log level, set the `AZURE_LOG_LEVEL` environment variable.

For instance, verbose logs can be enabled in Python as follows:

```
import os
import duckdb

os.environ["AZURE_LOG_LEVEL"] = "verbose"

duckdb.sql("CREATE SECRET myaccount (TYPE azure, PROVIDER credential_chain, SCOPE
'az://myaccount.blob.core.windows.net/')")
duckdb.sql("SELECT count(*) FROM 'az://myaccount.blob.core.windows.net/path/to/blob.parquet'")
```

Difference between ADLS and Blob Storage

Even though ADLS implements similar functionality as the Blob storage, there are some important performance benefits to using the ADLS endpoints for globbing, especially when using (complex) glob patterns.

To demonstrate, let's look at an example of how a glob is performed internally using the Blob and ADLS endpoints, respectively.

Using the following filesystem:

```
root
├── l_receipmonth=1997-10
│   ├── l_shipmode=AIR
│   │   └── data_0.csv
│   ├── l_shipmode=SHIP
│   │   └── data_0.csv
```

```
│   └── l_shipmode=TRUCK
│       └── data_0.csv
├── l_receipmonth=1997-11
│   ├── l_shipmode=AIR
│   │   └── data_0.csv
│   ├── l_shipmode=SHIP
│   │   └── data_0.csv
│   └── l_shipmode=TRUCK
│       └── data_0.csv
└── l_receipmonth=1997-12
    ├── l_shipmode=AIR
    │   └── data_0.csv
    ├── l_shipmode=SHIP
    │   └── data_0.csv
    └── l_shipmode=TRUCK
        └── data_0.csv
```

The following query is performed through the Blob endpoint:

```
SELECT count(*)
FROM 'az://root/l_receipmonth=1997-*/l_shipmode=SHIP/*.csv';
```

It will perform the following steps:

- List all the files with the prefix `root/l_receipmonth=1997-`

  ```
  - root/l_receipmonth=1997-10/l_shipmode=SHIP/data_0.csv
  - root/l_receipmonth=1997-10/l_shipmode=AIR/data_0.csv
  - root/l_receipmonth=1997-10/l_shipmode=TRUCK/data_0.csv
  - root/l_receipmonth=1997-11/l_shipmode=SHIP/data_0.csv
  - root/l_receipmonth=1997-11/l_shipmode=AIR/data_0.csv
  - root/l_receipmonth=1997-11/l_shipmode=TRUCK/data_0.csv
  - root/l_receipmonth=1997-12/l_shipmode=SHIP/data_0.csv
  - root/l_receipmonth=1997-12/l_shipmode=AIR/data_0.csv
  - root/l_receipmonth=1997-12/l_shipmode=TRUCK/data_0.csv
  ```

- Filter the result with the requested pattern `root/l_receipmonth=1997-*/l_shipmode=SHIP/*.csv`

  ```
  - root/l_receipmonth=1997-10/l_shipmode=SHIP/data_0.csv
  - root/l_receipmonth=1997-11/l_shipmode=SHIP/data_0.csv
  - root/l_receipmonth=1997-12/l_shipmode=SHIP/data_0.csv
  ```

Meanwhile, the same query can be performed through the datalake endpoint as follows:

```
SELECT count(*)
FROM 'abfss://root/l_receipmonth=1997-*/l_shipmode=SHIP/*.csv';
```

This will perform the following steps:

- List all directories in `root/`

  ```
  - root/l_receipmonth=1997-10
  - root/l_receipmonth=1997-11
  - root/l_receipmonth=1997-12
  ```

- Filter and list subdirectories: `root/l_receipmonth=1997-10`, `root/l_receipmonth=1997-11`, `root/l_receipmonth=1997-12`

  ```
  - root/l_receipmonth=1997-10/l_shipmode=SHIP
  - root/l_receipmonth=1997-10/l_shipmode=AIR
  - root/l_receipmonth=1997-10/l_shipmode=TRUCK
  - root/l_receipmonth=1997-11/l_shipmode=SHIP
  ```

```
- root/l_receipmonth=1997-11/l_shipmode=AIR
- root/l_receipmonth=1997-11/l_shipmode=TRUCK
- root/l_receipmonth=1997-12/l_shipmode=SHIP
- root/l_receipmonth=1997-12/l_shipmode=AIR
- root/l_receipmonth=1997-12/l_shipmode=TRUCK
```

- Filter and list subdirectories: `root/l_receipmonth=1997-10/l_shipmode=SHIP`, `root/l_receipmonth=1997-11/l_shipmode=SHIP`, `root/l_receipmonth=1997-12/l_shipmode=SHIP`

```
- root/l_receipmonth=1997-10/l_shipmode=SHIP/data_0.csv
- root/l_receipmonth=1997-11/l_shipmode=SHIP/data_0.csv
- root/l_receipmonth=1997-12/l_shipmode=SHIP/data_0.csv
```

As you can see because the Blob endpoint does not support the notion of directories, the filter can only be performed after the listing, whereas the ADLS endpoint will list files recursively. Especially with higher partition/directory counts, the performance difference can be very significant.

Delta Extension

The `delta` extension adds support for the Delta Lake open-source storage format. It is built using the Delta Kernel. The extension offers **read and write support** for Delta tables, both local and remote.

For implementation details, see the announcement blog post.

> **Warning.** We are aware of a regression in Azure Onelake which appears to be a consequence of a change in `delta-kernel-rs`. You can track the issue on GitHub.

> To connect to Unity Catalog, DuckDB has the `unity_catalog` extension.

Installing and Loading

The `delta` extension will be transparently autoloaded on first use from the official extension repository. If you would like to install and load it manually, run:

```
INSTALL delta;
LOAD delta;
```

Usage

To scan a local Delta table, run:

```
SELECT *
FROM delta_scan('file:///some/path/on/local/machine');
```

Reading from an S3 Bucket

To scan a Delta table in an S3 bucket, run:

```
SELECT *
FROM delta_scan('s3://some/delta/table');
```

For authenticating to S3 buckets, DuckDB Secrets are supported:

```
CREATE SECRET (
    TYPE s3,
    PROVIDER credential_chain
);
SELECT *
FROM delta_scan('s3://some/delta/table/with/auth');
```

To scan public buckets on S3, you may need to pass the correct region by creating a secret containing the region of your public S3 bucket:

```
CREATE SECRET (
    TYPE s3,
    REGION 'my-region'
);
SELECT *
FROM delta_scan('s3://some/public/table/in/my-region');
```

Reading from Azure Blob Storage

To scan a Delta table in an Azure Blob Storage bucket, run:

```
SELECT *
FROM delta_scan('az://my-container/my-table');
```

For authenticating to Azure Blob Storage, DuckDB Secrets are supported:

```
CREATE SECRET (
    TYPE azure,
    PROVIDER credential_chain
);
SELECT *
FROM delta_scan('az://my-container/my-table-with-auth');
```

Reading from Google Cloud Storage

To scan a Delta table in a GCS bucket, use HMAC keys and create a secret:

```
CREATE SECRET (
    TYPE gcs,
    KEY_ID '<hmac-key-id>',
    SECRET '<hmac-secret>'
);
SELECT *
FROM delta_scan('gs://my-bucket/my-delta-table');
```

Appending Data

To append rows to a Delta table, attach it and use `INSERT INTO`:

```
ATTACH 's3://my-bucket/my-delta-table' AS my_table (TYPE delta);
INSERT INTO my_table SELECT * FROM other_table;
```

Time Travel

To read a specific version of a Delta table, attach it and use the `AT (VERSION => n)` clause:

```
ATTACH 's3://my-bucket/my-delta-table' AS my_table (TYPE delta);
SELECT * FROM my_table AT (VERSION => 5);
```

Alternatively, pin a version at attach time:

```
ATTACH 's3://my-bucket/my-delta-table' AS my_table (TYPE delta, VERSION 5);
```

Checkpointing

To compact the Delta log of an attached table into a checkpoint file:

```
ATTACH 'path/to/my-delta-table' AS my_table (TYPE delta);
CHECKPOINT my_table;
```

Idempotent Appends

The `delta` extension exposes an idempotent-append API that uses Delta's per-application transaction versions to give exactly-once semantics: an append tagged with an `app_id` and a version is only committed if the table's currently recorded version for that `app_id` matches the expected previous version. This lets a producer safely retry a batch without duplicating it.

Within a transaction, tag the append with `delta_set_transaction_version(<table>, <app_id>, <new_version>, <expected_previous_version>)`:

```
ATTACH 'path/to/my-delta-table' AS my_table (TYPE delta);

BEGIN TRANSACTION;
CALL delta_set_transaction_version('my_table', 'my_app_id', 1::UBIGINT, NULL::UBIGINT);
INSERT INTO my_table VALUES (1);
COMMIT;
```

On `COMMIT`, the version is compared-and-swapped: if another process advanced the version for `my_app_id` in the meantime, the commit fails. Aborting the transaction leaves the version unchanged. Read the current version with `delta_get_transaction_version(<table>, <app_id>)`, which returns `NULL` if no version has been recorded yet.

Attach Options

When attaching a Delta table you can pass the following options to `ATTACH`:

Option	Type	Default	Description
`VERSION`	`UBIGINT`	latest	Pin the attached table to a specific table version.
`PIN_SNAPSHOT`	`BOOLEAN`	`false`	Resolve the table snapshot once at attach time and reuse it, rather than re-resolving the latest version per query.
`PUSHDOWN_PARTITION_INFO`	`BOOLEAN`	`true`	Push down partition information so that whole files can be skipped based on partition values.
`PUSHDOWN_FILTERS`	`VARCHAR`	`all`	Filter pushdown mode for file skipping. One of none, `all`, `constant_only`, `dynamic_only`.

```
ATTACH 's3://my-bucket/my-delta-table' AS my_table (
    TYPE delta,
    PIN_SNAPSHOT true,
    PUSHDOWN_FILTERS 'constant_only'
);
```

Inspecting Scanned Files

`delta_list_files` returns the data files a scan would read for a table, together with their cardinality, partition values, and whether they carry deletion vectors. This is useful for understanding the effect of data skipping:

```
SELECT * FROM delta_list_files('file:///some/path/on/local/machine');
```

Column	Type	Description
`data_file`	`VARCHAR`	Path to the Parquet data file.
`cardinality`	`UBIGINT`	Number of rows in the file.
`partitions`	`MAP(VARCHAR, VARCHAR)`	Partition column values for the file.
`have_deletes`	`BOOLEAN`	Whether the file has an associated deletion vector.

Credential Chains in Delta

DuckDB Delta uses `delta-kernel-rs` and `object_store` for some network operations. These systems have a different ordering (and inclusion defaults) for credential chains. If your system has multiple credential sources available, e.g., both Service Principal via the environment and a CLI-based option, credential loading behavior may be inconsistent.

To avoid ambiguities, we recommend that you configure exactly one available credential type in your production chain secrets.

Settings

The `delta` extension adds the following settings:

Setting	Type	Default	Description
`delta_kernel_logging`	`BOOLEAN`	`false`	Forward the internal logging of the Delta Kernel to the DuckDB logger. May impact performance even when DuckDB logging is disabled.
`delta_scan_explain_files_filtered`	`BOOLEAN`	`true`	Add the filtered files to the `EXPLAIN` output. May impact the performance of `delta_scan` during `EXPLAIN ANALYZE` queries.

Features

The `delta` extension supports:

- multithreaded scans and Parquet metadata reading
- data skipping/filter pushdown
  - skipping row groups in file (based on Parquet metadata)
  - skipping complete files (based on Delta partition information)
- projection pushdown
- scanning tables with deletion vectors
- all primitive types
- structs
- VARIANT type
- blind appends (`INSERT INTO`)
- cloud storage (AWS S3, Azure, GCS) with secrets

Supported Platforms

The `delta` extension currently only supports the following platforms:

- Linux AMD64 (x86_64 and ARM64): `linux_amd64` and `linux_arm64`
- macOS Intel and Apple Silicon: `osx_amd64` and `osx_arm64`
- Windows AMD64: `windows_amd64`

Support for the other DuckDB platforms is work-in-progress.

Using delta-rs with DuckDB

In this example, we create a Delta table with the `delta-rs` Python binding, then we use the `delta` extension of DuckDB to read it. We also showcase how to do other read operations with DuckDB, like reading the change data feed using the Arrow zero-copy integration. This operation can also be lazy if reading bigger data by using Arrow Datasets.

DuckLake

> DuckLake 1.0 was released in April 2026. Read the announcement blog post.

The `ducklake` extension adds support for attaching to databases stored in the DuckLake format. The complete documentation of this extension is available at the DuckLake website.

Installing and Loading

To install `ducklake`, run:

```
INSTALL ducklake;
```

The `ducklake` extension will be transparently autoloaded on first use in an `ATTACH` clause. If you would like to load it manually, run:

```
LOAD ducklake;
```

Usage

```
ATTACH 'ducklake:metadata.ducklake' AS my_ducklake (DATA_PATH 'data_files');
USE my_ducklake;
```

Tables

In DuckDB, the `ducklake` extension stores the catalog tables for a DuckLake named `my_ducklake`{:.language-sql .highlight} in the `__ducklake_metadata_<my_ducklake>`{:.language-sql .highlight} catalog.

Functions

Note that DuckLake registers several functions. These should be called with the catalog name as the first argument, e.g.:

```
FROM ducklake_snapshots('my_ducklake');
```

snapshot_id int64	snapshot_time timestamp with time zone	schema_version int64	changes map(varchar, varchar[])
0	2025-05-26 11:41:10.838+02	0	{schemas_created=[main]}

`ducklake_snapshots`

Returns the snapshots stored in the DuckLake catalog name `catalog`.

Parameter name	Parameter type	Named parameter	Description
`catalog`	VARCHAR	no	

The information is encoded into a table with the following schema:

Column name	Column type
snapshot_id	BIGINT
snapshot_time	TIMESTAMP WITH TIME ZONE
schema_version	BIGINT
changes	MAP(VARCHAR, VARCHAR[])

ducklake_table_info

The ducklake_table_info function returns information on the tables stored in the DuckLake catalog named catalog.

Parameter name	Parameter type	Named parameter	Description
catalog	VARCHAR	no	

The information is encoded into a table with the following schema:

Column name	Column type
table_name	VARCHAR
schema_id	BIGINT
table_id	BIGINT
table_uuid	UUID
file_count	BIGINT
file_size_bytes	BIGINT
delete_file_count	BIGINT
delete_file_size_bytes	BIGINT

ducklake_table_insertions

The ducklake_table_insertions function returns the rows inserted in a given table between snapshots of given versions or timestamps. The function has two variants, depending on whether start_snapshot and end_snapshot have types BIGINT or TIMESTAMP WITH TIME ZONE.

Parameter name	Parameter type	Named parameter	Description
catalog	VARCHAR	no	
schema_name	VARCHAR	no	
table_name	VARCHAR	no	
start_snapshot	BIGINT / TIMESTAMP WITH TIME ZONE	no	
end_snapshot	BIGINT / TIMESTAMP WITH TIME ZONE	no	

The schema of the table returned by the function is equivalent to that of the table table_name.

`ducklake_table_deletions`

The `ducklake_table_deletions` function returns the rows deleted from a given table between snapshots of given versions or timestamps. The function has two variants, depending on whether `start_snapshot` and `end_snapshot` have types `BIGINT` or `TIMESTAMP WITH TIME ZONE`.

Parameter name	Parameter type	Named parameter	Description
`catalog`	`VARCHAR`	no	
`schema_name`	`VARCHAR`	no	
`table_name`	`VARCHAR`	no	
`start_snapshot`	`BIGINT` / `TIMESTAMP WITH TIME ZONE`	no	
`end_snapshot`	`BIGINT` / `TIMESTAMP WITH TIME ZONE`	no	

The schema of the table returned by the function is equivalent to that of the table `table_name`.

`ducklake_table_changes`

The `ducklake_table_changes` function returns the rows changed in a given table between snapshots of given versions or timestamps. The function has two variants, depending on whether `start_snapshot` and `end_snapshot` have types `BIGINT` or `TIMESTAMP WITH TIME ZONE`.

Parameter name	Parameter type	Named parameter	Description
`catalog`	`VARCHAR`	no	
`schema_name`	`VARCHAR`	no	
`table_name`	`VARCHAR`	no	
`start_snapshot`	`BIGINT` / `TIMESTAMP WITH TIME ZONE`	no	
`end_snapshot`	`BIGINT` / `TIMESTAMP WITH TIME ZONE`	no	

The schema of the table returned by the function contains the following three columns plus the schema of the table `table_name`.

Column name	Column type	Description
`snapshot_id`	`BIGINT`	
`rowid`	`BIGINT`	
`change_type`	`VARCHAR`	The type of change: `insert` or `delete`

Commands

`ducklake_cleanup_old_files`

The `ducklake_cleanup_old_files` function cleans up old files in the DuckLake denoted by `catalog`. Upon success, it returns a table with a single column (`Success`) and 0 rows.

Parameter name	Parameter type	Named parameter	Description
`catalog`	`VARCHAR`	no	
`cleanup_all`	`BOOLEAN`	yes	
`dry_run`	`BOOLEAN`	yes	
`older_than`	`TIMESTAMP WITH TIME ZONE`	yes	

`ducklake_expire_snapshots`

The `ducklake_expire_snapshots` function expires snapshots with the versions specified by the `versions` parameter or the ones older than the `older_than` parameter. Upon success, it returns a table with a single column (`Success`) and 0 rows.

Parameter name	Parameter type	Named parameter	Description
`catalog`	`VARCHAR`	no	
`versions`	`UBIGINT[]`	yes	
`older_than`	`TIMESTAMP WITH TIME ZONE`	yes	

`ducklake_merge_adjacent_files`

The `ducklake_merge_adjacent_files` function merges adjacent files in the storage. Upon success, it returns a table with a single column (`Success`) and 0 rows.

Parameter name	Parameter type	Named parameter	Description
`catalog`	`VARCHAR`	no	

Compatibility Matrix

The DuckLake specification and the `ducklake` DuckDB extension are currently released together. See the Compatibility Matrix.

Encodings Extension

The `encodings` extension adds support for reading CSVs using more than 1,000 character encodings.

For a complete list of supported `encodings`, see All Supported Encodings. For detailed information on character encoding, see the ICU data repository.

Installing and Loading

```
INSTALL encodings;
LOAD encodings;
```

Usage

Refer to the `encoding` while reading from files.

To read a `.csv` file with `shift_jis` encoding:

```
FROM read_csv('my_shift_jis.csv', encoding = 'shift_jis');
```

To read a `.csv` file with `windows-1251-2000` encoding:

```
FROM read_csv('my_windows_1251_2000.csv', encoding = 'windows-1251-2000');
```

To read a `.csv` file with `windows-1252-2000` encoding:

```
FROM read_csv('my_windows_1252_2000.csv', encoding = 'windows-1252-2000');
```

To read a `.csv` file with EUC_CN encoding:

```
FROM read_csv('my_euc_cn.csv', encoding = 'EUC_CN');
```

All Supported Encodings

The following table is an alphabetized list of all `encoding` values supported by DuckDB using the `encodings` core extension:

Id	Encoding
1	5601
2	8859_1
3	8859_10
4	8859_15

Excel Extension

The `excel` extension provides functions to format numbers per Excel's formatting rules by wrapping the i18npool library and to read/write Excel (`.xlsx`) files. However, please note that `.xls` files are not supported.

Installing and Loading

The `excel` extension will be transparently autoloaded on first use from the official extension repository. If you would like to install and load it manually, run:

```
INSTALL excel;
LOAD excel;
```

Excel Scalar Functions

Function	Description
`excel_text(number, format_string)`	Format the given `number` per the rules given in the `format_string`
`text(number, format_string)`	Alias for `excel_text`

Examples

```
SELECT excel_text(1_234_567.897, 'h:mm AM/PM') AS timestamp;
```

timestamp
9:31 PM

```
SELECT excel_text(1_234_567.897, 'h AM/PM') AS timestamp;
```

timestamp
9 PM

Reading XLSX Files

Reading a `.xlsx` file is as simple as just SELECTing from it immediately, e.g.:

```
SELECT *
FROM 'test.xlsx';
```

a	b
1.0	2.0
3.0	4.0

However, if you want to set additional options to control the import process, you can use the `read_xlsx` function instead. The following named parameters are supported.

Option	Type	Default	Description
`header`	BOOLEAN	*Automatically inferred*	Whether to treat the first row as containing the names of the resulting columns.
`sheet`	VARCHAR	*Automatically inferred*	The name of the sheet in the xlsx file to read. Default is the first sheet.
`all_varchar`	BOOLEAN	false	Whether to read all cells as containing VARCHARs.
`ignore_errors`	BOOLEAN	false	Whether to ignore errors and silently replace cells that can't be cast to the corresponding inferred column type with `NULL`'s.
`range`	VARCHAR	*Automatically inferred*	The range of cells to read, in spreadsheet notation. For example, `A1:B2` reads the cells from A1 to B2. If not specified the resulting range will be inferred as rectangular region of cells between the first row of consecutive non-empty cells and the first empty row spanning the same columns.
`stop_at_empty`	BOOLEAN	*Automatically inferred*	Whether to stop reading the file when an empty row is encountered. If an explicit `range` option is provided, this is `false` by default, otherwise `true`.
`empty_as_varchar`	BOOLEAN	false	Whether to treat empty cells as VARCHAR instead of DOUBLE when trying to automatically infer column types.

```
SELECT *
FROM read_xlsx('test.xlsx', header = true);
```

a	b
1.0	2.0
3.0	4.0

Alternatively, the COPY statement with the XLSX format option can be used to import an Excel file into an existing table, in which case the types of the columns in the target table will be used to coerce the types of the cells in the Excel file.

```
CREATE TABLE test (a DOUBLE, b DOUBLE);
COPY test FROM 'test.xlsx' WITH (FORMAT xlsx, HEADER);
SELECT * FROM test;
```

Type and Range Inference

Because Excel itself only really stores numbers or strings in cells, and does not enforce that all cells in a column are of the same type, the `excel` extension has to do some guesswork to ”infer” and decide the types of the columns when importing an Excel sheet. While almost all columns are inferred as either DOUBLE or VARCHAR, there are some caveats:

- `TIMESTAMP`, `TIME`, `DATE` and `BOOLEAN` types are inferred when possible based on the *format* applied to the cell.

- Text cells containing TRUE and FALSE are inferred as BOOLEAN.
- Empty cells are considered to be DOUBLE by default, unless the `empty_as_varchar` option is set to `true`, in which case they are typed as VARCHAR.

If the `all_varchar` option is set to `true`, none of the above applies and all cells are read as VARCHAR.

When no types are specified explicitly, (e.g., when using the `read_xlsx` function instead of `COPY ... TO ... FROM '<file>.xlsx'`{:.language-sql .highlight}) the types of the resulting columns are inferred based on the first "data" row in the sheet, that is:

- If no explicit range is given
  - The first row after the header if a header is found or forced by the `header` option
  - The first non-empty row in the sheet if no header is found or forced
- If an explicit range is given
  - The second row of the range if a header is found in the first row or forced by the `header` option
  - The first row of the range if no header is found or forced

This can sometimes lead to issues if the first "data row" is not representative of the rest of the sheet (e.g., it contains empty cells) in which case the `ignore_errors` or `empty_as_varchar` options can be used to work around this.

However, when the `COPY ... FROM '<file>.xlsx'`{:.language-sql .highlight} syntax is used, no type inference is done and the types of the resulting columns are determined by the types of the columns in the table being copied to. All cells will simply be converted by casting from DOUBLE or VARCHAR to the target column type.

Writing XLSX Files

Writing `.xlsx` files is supported using the COPY statement with XLSX given as the format. The following additional parameters are supported.

Option	Type	Default	Description
`header`	BOOLEAN	`false`	Whether to write the column names as the first row in the sheet
`sheet`	VARCHAR	`Sheet1`	The name of the sheet in the xlsx file to write.
`sheet_row_limit`	INTEGER	`1048576`	The maximum number of rows in a sheet. An error is thrown if this limit is exceeded.

> **Warning.** Many tools only support a maximum of 1,048,576 rows in a sheet, so increasing the `sheet_row_limit` may render the resulting file unreadable by other software.

These are passed as options to the COPY statement after the FORMAT, e.g.:

```
CREATE TABLE test AS
    SELECT *
    FROM (VALUES (1, 2), (3, 4)) AS t(a, b);
COPY test TO 'test.xlsx' WITH (FORMAT xlsx, HEADER true);
```

Type Conversions

Because XLSX files only really support storing numbers or strings – the equivalent of VARCHAR and DOUBLE, the following type conversions are applied when writing XLSX files.

- Numeric types are cast to DOUBLE when writing to an XLSX file.

- Temporal types (`TIMESTAMP`, `DATE`, `TIME`, etc.) are converted to excel "serial" numbers, that is the number of days since 1900-01-01 for dates and the fraction of a day for times. These are then styled with a "number format" so that they appear as dates or times when opened in Excel.
- `TIMESTAMP_TZ` and `TIME_TZ` are cast to UTC `TIMESTAMP` and `TIME` respectively, with the timezone information being lost.
- `BOOLEAN`s are converted to `1` and `0`, with a "number format" applied to make them appear as `TRUE` and `FALSE` in Excel.
- All other types are cast to `VARCHAR` and then written as text cells.

Full-Text Search Extension

Full-Text Search is an extension to DuckDB that allows for search through strings, similar to SQLite's FTS5 extension.

Installing and Loading

The `fts` extension will be transparently autoloaded on first use from the official extension repository. If you would like to install and load it manually, run:

```
INSTALL fts;
LOAD fts;
```

Usage

The extension adds two PRAGMA statements to DuckDB: one to create, and one to drop an index. Additionally, a scalar macro `stem` is added, which is used internally by the extension.

`PRAGMA create_fts_index`

```
create_fts_index(input_table, input_id, *input_values, stemmer = 'porter',
                 stopwords = 'english', ignore = '(\\.|[^a-z])+',
                 strip_accents = 1, lower = 1, overwrite = 0)
```

PRAGMA that creates a FTS index for the specified table.

Name	Type	Description
`input_table`	VARCHAR	Qualified name of specified table, e.g., `'table_name'` or `'main.table_name'`
`input_id`	VARCHAR	Column name of document identifier, e.g., `'document_identifier'`
`input_values...`	VARCHAR	Column names of the text fields to be indexed (vararg), e.g., `'text_field_1'`, `'text_field_2'`, ..., `'text_field_N'`, or `'\*'` for all columns in input_table of type VARCHAR
`stemmer`	VARCHAR	The type of stemmer to be used. One of `'arabic'`, `'basque'`, `'catalan'`, `'danish'`, `'dutch'`, `'english'`, `'finnish'`, `'french'`, `'german'`, `'greek'`, `'hindi'`, `'hungarian'`, `'indonesian'`, `'irish'`, `'italian'`, `'lithuanian'`, `'nepali'`, `'norwegian'`, `'porter'`, `'portuguese'`, `'romanian'`, `'russian'`, `'serbian'`, `'spanish'`, `'swedish'`, `'tamil'`, `'turkish'`, or `'none'` if no stemming is to be used. Defaults to `'porter'`
`stopwords`	VARCHAR	Qualified name of table containing a single VARCHAR column containing the desired stopwords, or `'none'` if no stopwords are to be used. Defaults to `'english'` for a pre-defined list of 571 English stopwords
`ignore`	VARCHAR	Regular expression of patterns to be ignored. Defaults to `'(\\.|[^a-z])+'`, ignoring all escaped and non-alphabetic lowercase characters
`strip_accents`	BOOLEAN	Whether to remove accents (e.g., convert á to a). Defaults to 1

Name	Type	Description
`lower`	BOOLEAN	Whether to convert all text to lowercase. Defaults to `1`
`overwrite`	BOOLEAN	Whether to overwrite an existing index on a table. Defaults to `0`

This PRAGMA builds the index under a newly created schema. The schema will be named after the input table: if an index is created on table `'main.table_name'`, then the schema will be named `'fts_main_table_name'`.

`PRAGMA drop_fts_index`

```
drop_fts_index(input_table)
```

Drops a FTS index for the specified table.

Name	Type	Description
`input_table`	VARCHAR	Qualified name of input table, e.g., `'table_name'` or `'main.table_name'`

`match_bm25` Function

```
match_bm25(input_id, query_string, fields := NULL, k := 1.2, b := 0.75, conjunctive := 0)
```

When an index is built, this retrieval macro is created that can be used to search the index.

Name	Type	Description
`input_id`	VARCHAR	Column name of document identifier, e.g., `'document_identifier'`
`query_string`	VARCHAR	The string to search the index for
`fields`	VARCHAR	Comma-separated list of fields to search in, e.g., `'text_field_2, text_field_N'`. Defaults to `NULL` to search all indexed fields
k	DOUBLE	Parameter *k1* in the Okapi BM25 retrieval model. Defaults to `1.2`
b	DOUBLE	Parameter *b* in the Okapi BM25 retrieval model. Defaults to `0.75`
`conjunctive`	BOOLEAN	Whether to make the query conjunctive i.e., all terms in the query string must be present in order for a document to be retrieved

`stem` Function

```
stem(input_string, stemmer)
```

Reduces words to their base. Used internally by the extension.

Name	Type	Description
`input_string`	VARCHAR	The column or constant to be stemmed.

Name	Type	Description
`stemmer`	VARCHAR	The type of stemmer to be used. One of `'arabic'`, `'basque'`, `'catalan'`, `'danish'`, `'dutch'`, `'english'`, `'finnish'`, `'french'`, `'german'`, `'greek'`, `'hindi'`, `'hungarian'`, `'indonesian'`, `'irish'`, `'italian'`, `'lithuanian'`, `'nepali'`, `'norwegian'`, `'porter'`, `'portuguese'`, `'romanian'`, `'russian'`, `'serbian'`, `'spanish'`, `'swedish'`, `'tamil'`, `'turkish'`, or `'none'` if no stemming is to be used.

Example Usage

Create a table and fill it with text data:

```
CREATE TABLE documents (
    document_identifier VARCHAR,
    text_content VARCHAR,
    author VARCHAR,
    doc_version INTEGER
);
INSERT INTO documents
    VALUES ('doc1',
            'The mallard is a dabbling duck that breeds throughout the temperate.',
            'Hannes Mühleisen',
            3),
           ('doc2',
            'The cat is a domestic species of small carnivorous mammal.',
            'Laurens Kuiper',
            2
           );
```

Build the index, and make both the `text_content` and `author` columns searchable.

```
PRAGMA create_fts_index(
    'documents', 'document_identifier', 'text_content', 'author'
);
```

Search the `author` field index for documents that are authored by `Muhleisen`. This retrieves `doc1`:

```
SELECT document_identifier, text_content, score
FROM (
    SELECT *, fts_main_documents.match_bm25(
        document_identifier,
        'Muhleisen',
        fields := 'author'
    ) AS score
    FROM documents
) sq
WHERE score IS NOT NULL
  AND doc_version > 2
ORDER BY score DESC;
```

document_identifier	text_content	score
doc1	The mallard is a dabbling duck that breeds throughout the temperate.	0.0

Search for documents about `small cats`. This retrieves `doc2`:

```sql
SELECT document_identifier, text_content, score
FROM (
    SELECT *, fts_main_documents.match_bm25(
        document_identifier,
        'small cats'
    ) AS score
    FROM documents
) sq
WHERE score IS NOT NULL
ORDER BY score DESC;
```

document_identifier	text_content	score
doc2	The cat is a domestic species of small carnivorous mammal.	0.0

> **Warning.** The FTS index will not update automatically when the input table changes. A workaround of this limitation can be recreating the index to refresh.

httpfs (HTTP and S3)

httpfs Extension for HTTP and S3 Support

The `httpfs` extension is an autoloadable extension implementing a file system that allows reading remote/writing remote files. For plain HTTP(S), only file reading is supported. For object storage using the S3 API, the `httpfs` extension supports reading/writing/globbing files.

Installation and Loading

The `httpfs` extension will be, by default, autoloaded on first use of any functionality exposed by this extension.

To manually install and load the `httpfs` extension, run:

```
INSTALL httpfs;
LOAD httpfs;
```

HTTP(S)

The `httpfs` extension supports connecting to HTTP(S) endpoints.

S3 API

The `httpfs` extension supports connecting to S3 API endpoints.

HTTP(S) Support

With the `httpfs` extension, it is possible to directly query files over the HTTP(S) protocol. This works for all files supported by DuckDB or its various extensions, and provides read-only access.

```
SELECT *
FROM 'https://domain.tld/file.extension';
```

Partial Reading

For CSV files, files will be downloaded entirely in most cases, due to the row-based nature of the format. For Parquet files, DuckDB supports partial reading, i.e., it can use a combination of the Parquet metadata and HTTP range requests to only download the parts of the file that are actually required by the query. For example, the following query will only read the Parquet metadata and the data for the `column_a` column:

```
SELECT column_a
FROM 'https://domain.tld/file.parquet';
```

In some cases, no actual data needs to be read at all as they only require reading the metadata:

```
SELECT count(*)
FROM 'https://domain.tld/file.parquet';
```

Scanning Multiple Files

Scanning multiple files over HTTP(S) is also supported:

```
SELECT *
FROM read_parquet([
    'https://domain.tld/file1.parquet',
    'https://domain.tld/file2.parquet'
]);
```

Authenticating

To authenticate for an HTTP(S) endpoint, create an HTTP secret using the Secrets Manager:

```
CREATE SECRET http_auth (
    TYPE http,
    BEARER_TOKEN '<token>'
);
```

Or:

```
CREATE SECRET http_auth (
    TYPE http,
    EXTRA_HTTP_HEADERS MAP {
        'Authorization': 'Bearer <token>'
    }
);
```

HTTP Proxy

DuckDB supports HTTP proxies.

You can add an HTTP proxy using the Secrets Manager:

```
CREATE SECRET http_proxy (
    TYPE http,
    HTTP_PROXY '<http_proxy_url>',
    HTTP_PROXY_USERNAME '<username>',
    HTTP_PROXY_PASSWORD '<password>'
);
```

You can also set the scope for an HTTP proxy using the SCOPE keyword.

```
CREATE SECRET http_proxy (
    TYPE HTTP,
    SCOPE ['<https://duckdb.org>', '<https://some-other-website.org>'],
    HTTP_PROXY '<http_proxy_url>',
    HTTP_PROXY_USERNAME '<username>',
    HTTP_PROXY_PASSWORD '<password>'
);
```

Alternatively, you can add it via configuration options:

```
SET http_proxy = '<http_proxy_url>';
SET http_proxy_username = '<username>';
SET http_proxy_password = '<password>';
```

Note: You cannot set a proxy scope using the configurations options.

Using a Custom Certificate File

To use the `httpfs` extension with a custom certificate file, set the following configuration options prior to loading the extension:

```
LOAD httpfs;
SET ca_cert_file = '<certificate_file>';
SET enable_server_cert_verification = true;
```

If you would like to disable SSL verification for all HTTP requests using an HTTP secret you can do so with the following statement:

```
CREATE SECRET disable_ssl (
    TYPE HTTP,
    VERIFY_SSL 0
);
```

To enable it again for one specific endpoint, you can take advantage of the scope parameter:

```
CREATE SECRET enable_ssl_for_your_website (
    TYPE HTTP,
    SCOPE 'https://<your-website.com>',
    VERIFY_SSL 1
);
```

Hugging Face Support

The `httpfs` extension introduces support for the `hf://` protocol to access datasets hosted in Hugging Face repositories. See the announcement blog post for details.

Usage

Hugging Face repositories can be queried using the following URL pattern:

```
hf://datasets/<my_username>/<my_dataset>/<path_to_file>
```

For example, to read a CSV file, you can use the following query:

```
SELECT *
FROM 'hf://datasets/datasets-examples/doc-formats-csv-1/data.csv';
```

Where:

- `datasets-examples` is the name of the user/organization
- `doc-formats-csv-1` is the name of the dataset repository
- `data.csv` is the file path in the repository

The result of the query is:

kind	sound
dog	woof
cat	meow
pokemon	pika
human	hello

To read a JSONL file, you can run:

```
SELECT *
FROM 'hf://datasets/datasets-examples/doc-formats-jsonl-1/data.jsonl';
```

Finally, for reading a Parquet file, use the following query:

```
SELECT *
FROM 'hf://datasets/datasets-examples/doc-formats-parquet-1/data/train-00000-of-00001.parquet';
```

Each of these commands reads the data from the specified file format and displays it in a structured tabular format. Choose the appropriate command based on the file format you are working with.

Creating a Local Table

To avoid accessing the remote endpoint for every query, you can save the data in a DuckDB table by running a `CREATE TABLE ... AS` command. For example:

```
CREATE TABLE data AS
    SELECT *
    FROM 'hf://datasets/datasets-examples/doc-formats-csv-1/data.csv';
```

Then, simply query the `data` table as follows:

```
SELECT *
FROM data;
```

Multiple Files

To query all files under a specific directory, you can use a glob pattern. For example:

```
SELECT count(*) AS count
FROM 'hf://datasets/cais/mmlu/astronomy/*.parquet';
```

count
173

By using glob patterns, you can efficiently handle large datasets and perform comprehensive queries across multiple files, simplifying your data inspections and processing tasks. Here, you can see how you can look for questions that contain the word “planet” in astronomy:

```
SELECT count(*) AS count
FROM 'hf://datasets/cais/mmlu/astronomy/*.parquet'
WHERE question LIKE '%planet%';
```

count
21

Versioning and Revisions

In Hugging Face repositories, dataset versions or revisions are different dataset updates. Each version is a snapshot at a specific time, allowing you to track changes and improvements. In git terms, it can be understood as a branch or specific commit.

You can query different dataset versions/revisions by using the following URL:

```
hf://datasets/<my_username>/<my_dataset>@<my_branch>/<path_to_file>
```

For example:

```
SELECT *
FROM 'hf://datasets/datasets-examples/doc-formats-csv-1@~parquet/**/*.parquet';
```

kind	sound
dog	woof
cat	meow
pokemon	pika
human	hello

The previous query will read all Parquet files under the `~parquet` revision. This is a special branch where Hugging Face automatically generates the Parquet files of every dataset to enable efficient scanning.

Authentication

Configure your Hugging Face Token in the DuckDB Secrets Manager to access private or gated datasets. First, visit Hugging Face Settings – Tokens to obtain your access token. Second, set it in your DuckDB session using DuckDB's Secrets Manager. DuckDB supports two providers for managing secrets:

`CONFIG`

The user must pass all configuration information into the `CREATE SECRET` statement. To create a secret using the `CONFIG` provider, use the following command:

```
CREATE SECRET hf_token (
    TYPE huggingface,
    TOKEN 'your_hf_token'
);
```

`credential_chain`

Automatically tries to fetch credentials. For the Hugging Face token, it will try to get it from `~/.cache/huggingface/token`. To create a secret using the `credential_chain` provider, use the following command:

```
CREATE SECRET hf_token (
    TYPE huggingface,
    PROVIDER credential_chain
);
```

S3 API Support

The `httpfs` extension supports reading/writing/globbing files on object storage servers using the S3 API. S3 offers a standard API to read and write to remote files (while regular http servers, predating S3, do not offer a common write API). DuckDB conforms to the S3 API, that is now common among industry storage providers.

Platforms

The `httpfs` filesystem is tested with AWS S3, Minio, Google Cloud and lakeFS. Other services that implement the S3 API (such as Cloudflare R2 and Tigris) should also work, but not all features may be supported.

The following table shows which parts of the S3 API are required for each `httpfs` feature.

Feature	Required S3 API features
Public file reads	HTTP Range requests
Private file reads	Secret key or session token authentication
File glob	ListObjectsV2
File writes	Multipart upload

Configuration and Authentication

The preferred way to configure and authenticate to S3 endpoints is to use secrets. Multiple secret providers are available.

To migrate from the deprecated S3 API, use a defined secret with a profile. See the "Loading a Secret Based on a Profile" section.

`config` Provider

The default provider, `config` (i.e., user-configured), allows access to the S3 bucket by manually providing a key. For example:

```
CREATE OR REPLACE SECRET secret (
    TYPE s3,
    PROVIDER config,
    KEY_ID '<AKIAIOSFODNN7EXAMPLE>',
    SECRET '<wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY>',
    REGION '<us-east-1>'
);
```

> **Tip.** If you get an IO Error (`Connection error for HTTP HEAD`), configure the endpoint explicitly via `ENDPOINT 's3.<your-region>.amazonaws.com'`{:.language-sql .highlight}.

Now, to query using the above secret, simply query any `s3://` prefixed file:

```
SELECT *
FROM 's3://<your-bucket>/<your_file>.parquet';
```

`credential_chain` Provider

The `credential_chain` provider allows automatically fetching credentials using mechanisms provided by the AWS SDK. For example, to use the AWS SDK default provider:

```
CREATE OR REPLACE SECRET secret (
    TYPE s3,
    PROVIDER credential_chain
);
```

Again, to query a file using the above secret, simply query any `s3://` prefixed file.

DuckDB also allows specifying a specific chain using the `CHAIN` keyword. This takes a semicolon-separated list (`a;b;c`) of providers that will be tried in order. For example:

```
CREATE OR REPLACE SECRET secret (
    TYPE s3,
    PROVIDER credential_chain,
    CHAIN 'env;config'
);
```

The possible values for CHAIN are the following:

- config
- sts
- sso
- env
- instance
- process

The credential_chain provider also allows overriding the automatically fetched config. For example, to automatically load credentials, and then override the region, run:

```
CREATE OR REPLACE SECRET secret (
    TYPE s3,
    PROVIDER credential_chain,
    CHAIN config,
    REGION '<eu-west-1>'
);
```

Loading a Secret Based on a Profile To load credentials based on a profile which is not defined as a default from the AWS_PROFILE environment variable or as a default profile based on AWS SDK precedence, run:

```
CREATE OR REPLACE SECRET secret (
    TYPE s3,
    PROVIDER credential_chain,
    CHAIN config,
    PROFILE '<my_profile>'
);
```

This approach is equivalent to the deprecated S3 API's's method load_aws_credentials('<my_profile>').

Overview of S3 Secret Parameters

Below is a complete list of the supported parameters that can be used for both the config and credential_chain providers:

Name	Description	Secret	Type	Default
ENDPOINT	Specify a custom S3 endpoint	S3, GCS, R2	STRING	s3.amazonaws.com for S3,
KEY_ID	The ID of the key to use	S3, GCS, R2	STRING	-
REGION	The region for which to authenticate (should match the region of the bucket to query)	S3, GCS, R2	STRING	us-east-1
SECRET	The secret of the key to use	S3, GCS, R2	STRING	-
SESSION_TOKEN	Optionally, a session token can be passed to use temporary credentials	S3, GCS, R2	STRING	-
URL_COMPATIBILITY_MODE	Can help when URLs contain problematic characters	S3, GCS, R2	BOOLEAN	true

Name	Description	Secret	Type	Default
URL_STYLE	Either vhost or path	S3, GCS, R2	STRING	vhost for S3, path for R2 and GCS
USE_SSL	Whether to use HTTPS or HTTP	S3, GCS, R2	BOOLEAN	true
VERIFY_SSL	Whether to verify the SSL certificate of the server	S3, GCS, R2	BOOLEAN	true
ACCOUNT_ID	The R2 account ID to use for generating the endpoint URL	R2	STRING	-
KMS_KEY_ID	AWS KMS (Key Management Service) key for Server Side Encryption S3	S3	STRING	-
REQUESTER_PAYS	Allows use of "requester pays" S3 buckets	S3	BOOLEAN	false

Platform-Specific Secret Types

S3 Secrets The httpfs extension supports Server Side Encryption via the AWS Key Management Service (KMS) on S3 using the KMS_KEY_ID option:

```
CREATE OR REPLACE SECRET secret (
    TYPE s3,
    PROVIDER credential_chain,
    CHAIN config,
    REGION '<eu-west-1>',
    KMS_KEY_ID 'arn:aws:kms:<region>:<account_id>:<key>/<key_id>',
    SCOPE 's3://<bucket-sub-path>'
);
```

R2 Secrets While Cloudflare R2 uses the regular S3 API, DuckDB has a special Secret type, R2, to make configuring it a bit simpler:

```
CREATE OR REPLACE SECRET secret (
    TYPE r2,
    KEY_ID '<AKIAIOSFODNN7EXAMPLE>',
    SECRET '<wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY>',
    ACCOUNT_ID '<my_account_id>'
);
```

Note the addition of the ACCOUNT_ID which is used to generate the correct endpoint URL for you. Also note that R2 Secrets can also use both the CONFIG and credential_chain providers. However, since DuckDB uses an AWS client internally, when using credential_chain, the client will search for AWS credentials in the standard AWS credential locations (environment variables, credential files, etc.). Therefore, your R2 credentials must be made available as AWS environment variables (AWS_ACCESS_KEY_ID and AWS_SECRET_ACCESS_KEY) for the credential chain to work properly. Finally, R2 secrets are only available when using URLs starting with r2://, for example:

```
SELECT *
FROM read_parquet('r2://<some-file-that-uses-an-r2-secret>.parquet');
```

GCS Secrets While Google Cloud Storage is accessed by DuckDB using the S3 API, DuckDB has a special Secret type, GCS, to make configuring it a bit simpler:

```
CREATE OR REPLACE SECRET secret (
    TYPE gcs,
    KEY_ID '<my_hmac_access_id>',
    SECRET '<my_hmac_secret_key>'
);
```

Important: The `KEY_ID` and `SECRET` values must be HMAC keys generated specifically for Google Cloud Storage interoperability. These are not the same as regular GCP service account keys or access tokens. You can create HMAC keys by following the Google Cloud documentation for managing HMAC keys.

Note that the above secret will automatically have the correct Google Cloud Storage endpoint configured. Also note that GCS Secrets can also use both the `CONFIG` and `credential_chain` providers. However, since DuckDB uses an AWS client internally, when using `credential_chain`, the client will search for AWS credentials in the standard AWS credential locations (environment variables, credential files, etc.). Therefore, your GCS HMAC keys must be made available as AWS environment variables (`AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`) for the credential chain to work properly. Finally, GCS secrets are only available when using URLs starting with `gcs://` or `gs://`, for example:

```
SELECT *
FROM read_parquet('gcs://<some/file/that/uses/a/gcs/secret>.parquet');
```

Reading

Reading files from S3 is now as simple as:

```
SELECT *
FROM 's3://<your-bucket>/<filename>.<extension>';
```

Partial Reading

The `httpfs` extension supports partial reading from S3 buckets.

Reading Multiple Files

Multiple files are also possible, for example:

```
SELECT *
FROM read_parquet([
    's3://<your-bucket>/<filename-1>.parquet',
    's3://<your-bucket>/<filename-2>.parquet'
]);
```

Globbing

File globbing is implemented using the ListObjectsV2 API call and allows using filesystem-like glob patterns to match multiple files, for example:

```
SELECT *
FROM read_parquet('s3://<your-bucket>/*.parquet');
```

This query matches all files in the root of the bucket with the Parquet extension.

Several features for matching are supported, such as `*` to match any number of any character, `?` for any single character or `[0-9]` for a single character in a range of characters:

```
SELECT count(*) FROM read_parquet('s3://<your-bucket>/folder*/100?/t[0-9].parquet');
```

A useful feature when using globs is the `filename` option, which adds a column named `filename` that encodes the file that a particular row originated from:

```
SELECT *
FROM read_parquet('s3://<your-bucket>/*.parquet', filename = true);
```

This could for example result in:

column_a	column_b	filename
1	examplevalue1	s3://bucket-name/file1.parquet
2	examplevalue1	s3://bucket-name/file2.parquet

Hive Partitioning

DuckDB also offers support for the Hive partitioning scheme, which is available when using HTTP(S) and S3 endpoints.

Writing

Writing to S3 uses the multipart upload API. This allows DuckDB to robustly upload files at high speed. Writing to S3 works for both CSV and Parquet:

```
COPY table_name TO 's3://<your-bucket>/<filename>.<extension>';
```

Partitioned copy to S3 also works:

```
COPY table TO 's3://<your-bucket>/partitioned' (
    FORMAT parquet,
    PARTITION_BY (<part_col_a>, <part_col_b>)
);
```

An automatic check is performed for existing files/directories, which is currently quite conservative (and on S3 will add a bit of latency). To disable this check and force writing, an `OVERWRITE_OR_IGNORE` flag is added:

```
COPY table TO 's3://<your-bucket>/partitioned' (
    FORMAT parquet,
    PARTITION_BY (<part_col_a>, <part_col_b>),
    OVERWRITE_OR_IGNORE true
);
```

The naming scheme of the written files looks like this:

```
s3://<your-bucket>/partitioned/part_col_a=<val>/part_col_b=<val>/data_<thread_number>.parquet
```

Configuration

Some additional configuration options exist for the S3 upload, though the default values should suffice for most use cases.

Name	Description
`s3_uploader_max_parts_per_file`	Used for part size calculation, see AWS docs
`s3_uploader_max_filesize`	Used for part size calculation, see AWS docs
`s3_uploader_thread_limit`	Maximum number of uploader threads

Legacy Authentication Scheme for S3 API

Prior to version 0.10.0, DuckDB did not have a Secrets manager. Hence, the configuration of and authentication to S3 endpoints was handled via variables. This page documents the legacy authentication scheme for the S3 API.

> **Warning.** This page describes a legacy method to store secrets as DuckDB settings. This increases the risk of accidentally leaking secrets (e.g., by printing their values). Therefore, avoid using these methods for storing secrets. The recommended way to configure and authenticate of S3 endpoints is to use secrets.

Legacy Authentication Scheme

To be able to read or write from S3, the correct region should be set:

```
SET s3_region = 'us-east-1';
```

Optionally, the endpoint can be configured in case a non-AWS object storage server is used:

```
SET s3_endpoint = '<domain>.<tld>:<port>';
```

If the endpoint is not SSL-enabled then run:

```
SET s3_use_ssl = false;
```

Switching between path-style and vhost-style URLs is possible using:

```
SET s3_url_style = 'path';
```

However, note that this may also require updating the endpoint. For example for AWS S3 it is required to change the endpoint to `s3.<region>.amazonaws.com`{:.language-sql .highlight}.

After configuring the correct endpoint and region, public files can be read. To also read private files, authentication credentials can be added:

```
SET s3_access_key_id = '<aws_access_key_id>';
SET s3_secret_access_key = '<aws_secret_access_key>';
```

Alternatively, temporary S3 credentials are also supported. They require setting an additional session token:

```
SET s3_session_token = '<aws_session_token>';
```

The aws extension allows for loading AWS credentials.

Per-Request Configuration

Aside from the global S3 configuration described above, specific configuration values can be used on a per-request basis. This allows for use of multiple sets of credentials, regions, etc. These are used by including them on the S3 URI as query parameters. All the individual configuration values listed above can be set as query parameters. For instance:

```
SELECT *
FROM 's3://bucket/file.parquet?s3_access_key_id=accessKey&s3_secret_access_key=secretKey';
```

Multiple configurations per query are also allowed:

```
SELECT *
FROM 's3://bucket/file.parquet?s3_access_key_id=accessKey1&s3_secret_access_key=secretKey1' t1
INNER JOIN 's3://bucket/file.csv?s3_access_key_id=accessKey2&s3_secret_access_key=secretKey2' t2;
```

Configuration

Some additional configuration options exist for the S3 upload, though the default values should suffice for most use cases.

Additionally, most of the configuration options can be set via environment variables:

DuckDB setting	Environment variable	Note
`s3_region`	`AWS_REGION`	Takes priority over `AWS_DEFAULT_REGION`
`s3_region`	`AWS_DEFAULT_REGION`	
`s3_access_key_id`	`AWS_ACCESS_KEY_ID`	
`s3_secret_access_key`	`AWS_SECRET_ACCESS_KEY`	
`s3_session_token`	`AWS_SESSION_TOKEN`	
`s3_endpoint`	`DUCKDB_S3_ENDPOINT`	
`s3_use_ssl`	`DUCKDB_S3_USE_SSL`	
`s3_requester_pays`	`DUCKDB_S3_REQUESTER_PAYS`	

Iceberg

Iceberg Extension

The `iceberg` extension implements support for the Apache Iceberg open table format. There are two ways to work with Iceberg in DuckDB:

- **Individual tables** are read directly from storage, by pointing at a table's metadata. This requires no catalog and is read-only.
- **Catalog-managed tables** are accessed by attaching an Iceberg REST catalog. This unlocks the full feature set, including writing.

This page covers the basics of both. See also:

- Iceberg REST Catalogs – connecting to specific catalogs (Amazon S3 Tables, AWS Glue, Cloudflare R2, Polaris, Lakekeeper, BigLake).
- Writing to Iceberg – create tables, insert, update, delete, merge, and evolve schemas.
- Functions and Settings Reference – all table functions, scalar functions, and settings.

Installing and Loading

The `iceberg` extension is installed and loaded automatically on first use. If you would like to install and load it manually, run:

```
INSTALL iceberg;
LOAD iceberg;
```

Updating the Extension

The `iceberg` extension often receives updates between DuckDB releases. To make sure that you have the latest version, update your extensions:

```
UPDATE EXTENSIONS;
```

Individual Tables

Individual Iceberg tables can be read directly from storage with the `iceberg_scan` function, without attaching to a catalog. To test the examples, download the `iceberg_data.zip` file and unzip it.

Common Parameters

Parameter	Type	Default	Description
`allow_moved_paths`	`BOOLEAN`	`false`	Allows scanning Iceberg tables that are moved
`metadata_compression_codec`	`VARCHAR`	`''`	Treats metadata files as when set to `'gzip'`
`snapshot_from_id`	`UBIGINT`	`NULL`	Access snapshot with a specific `id`
`snapshot_from_timestamp`	`TIMESTAMP`	`NULL`	Access snapshot with a specific `timestamp`

Parameter	Type	Default	Description
`version`	VARCHAR	`'?'`	Provides an explicit version string, hint file or guessing
`version_name_format`	VARCHAR	`'v%s%s.metadata.json,%s%s.metadata.json'`	Controls how versions are converted to metadata file names

Querying Individual Tables

```
SELECT count(*)
FROM iceberg_scan('data/iceberg/lineitem_iceberg', allow_moved_paths = true);
```

count_star()
51793

> The `allow_moved_paths` option ensures that some path resolution is performed, which allows scanning Iceberg tables that are moved.

You can also directly specify the current manifest in the query, this may be resolved from the catalog prior to the query, in this example the manifest version is a UUID. To do so, navigate to the `data/iceberg` directory and run:

```
SELECT count(*)
FROM iceberg_scan('lineitem_iceberg/metadata/v1.metadata.json');
```

count_star()
60175

The `iceberg` extension works together with the `httpfs` extension or the `azure` extension to access Iceberg tables in object stores such as S3 or Azure Blob Storage.

```
SELECT count(*)
FROM iceberg_scan('s3://bucketname/lineitem_iceberg/metadata/v1.metadata.json');
```

Accessing Iceberg Metadata

To access Iceberg Metadata, you can use the `iceberg_metadata` function:

```
SELECT *
FROM iceberg_metadata('data/iceberg/lineitem_iceberg', allow_moved_paths = true);
```

manifest_path	manifest_sequence_number	manifest_content	status	content	file_path	file_format	record_count
lineitem_iceberg/metadata/10eaca8a-1e1c-421e-ad6d-b232e5ee23d3-m1.avro	2	DATA	ADDED	EXISTING	lineitem_iceberg/data/00041-414-f3c73457-bbd6-4b92-9c15-17b241171b16-00001.parquet	PARQUET	51793

manifest_path	manifest_sequence_number	manifest_content	status	content	file_path	file_format	record_count
lineitem_iceberg/metadata/10eaca8a-1e1c-421e-ad6d-b232e5ee23d3-m0.avro	2	DATA	DELETED	EXISTING	lineitem_iceberg/data/00000-411-0792dcfe-4e25-4ca3-8ada-175286069a47-00001.parquet	PARQUET	60175

Visualizing Snapshots

To visualize the snapshots in an Iceberg table, use the `iceberg_snapshots` function:

```
SELECT *
FROM iceberg_snapshots('data/iceberg/lineitem_iceberg');
```

sequence_number	snapshot_id	timestamp_ms	manifest_list
1	3776207205136740581	2023-02-15 15:07:54.504	lineitem_iceberg/metadata/snap-3776207205136740581-1-cf3d0be5-cf70-453d-ad8f-48fdc412e608.avro
2	7635660646343998149	2023-02-15 15:08:14.73	lineitem_iceberg/metadata/snap-7635660646343998149-1-10eaca8a-1e1c-421e-ad6d-b232e5ee23d3.avro

> `iceberg_snapshots` does not take `allow_moved_paths`, `snapshot_from_id` or `snapshot_from_timestamp` as parameters.

Selecting Metadata Versions

By default, the `iceberg` extension will look for a `version-hint.text` file to identify the proper metadata version to use. This can be overridden by explicitly supplying a version number via the `version` parameter to the functions of the `iceberg` extension:

```
SELECT *
FROM iceberg_snapshots(
    'data/iceberg/lineitem_iceberg',
    version = '1'
);
```

By default, `iceberg` functions will look for both `v{version}.metadata.json` and `{version}.metadata.json` files, or `v{version}.gz.metadata.json` and `{version}.gz.metadata.json` when `metadata_compression_codec = 'gzip'` is specified. Other compression codecs are not supported.

If any text file is provided through the `version` parameter, it is opened and treated as a version hint file:

```
SELECT *
FROM iceberg_snapshots(
    'data/iceberg/lineitem_iceberg',
    version = 'version-hint.txt'
);
```

The `iceberg` extension will open this file and use the **entire content** of the file as a provided version number. Note that the entire content of the `version-hint.txt` file will be treated as a literal version name, with no encoding, escaping or trimming. This includes any whitespace, or unsafe characters which will be explicitly passed formatted into filenames in the logic described below.

Working with Alternative Metadata Naming Conventions

The `iceberg` extension can handle different metadata naming conventions by specifying them as a comma-delimited list of format strings via the `version_name_format` parameter. Each format string must contain two `%s` parameters. The first is the location of the version number in the metadata filename and the second is the location of the filename extension specified by the `metadata_compression_codec`. The behavior described above is provided by the default value of `"v%s%s.metadata.gz,%s%smetadata.gz`. If you had an alternatively named metadata file, e.g., `rev-2.metadata.json.gz`, the table can be read via the follow statement:

```
SELECT *
FROM iceberg_snapshots(
    'data/iceberg/alternative_metadata_gz_naming',
    version = '2',
    version_name_format = 'rev-%s.metadata.json%s',
    metadata_compression_codec = 'gzip'
);
```

"Guessing" Metadata Versions

By default, either a table version number or a `version-hint.text` **must** be provided for the `iceberg` extension to read a table. This is typically provided by an external data catalog. In the event neither is present, the `iceberg` extension can attempt to guess the latest version by passing `?` as the `version` parameter:

```
SELECT count(*)
FROM iceberg_scan(
    'data/iceberg/lineitem_iceberg_no_hint',
    version = '?',
    allow_moved_paths = true
);
```

The "latest" version is assumed to be the filename that is lexicographically largest when sorting the filenames. Collations are not considered. This behavior is not enabled by default as it may potentially violate ACID constraints. It can be enabled by setting `unsafe_enable_version_guessing` to `true`. When this is set, `iceberg` functions will attempt to guess the latest version by default before failing.

```
SET unsafe_enable_version_guessing = true;
SELECT count(*)
FROM iceberg_scan(
    'data/iceberg/lineitem_iceberg_no_hint',
    allow_moved_paths = true
);
```

Time Travel

To read a historical snapshot of a table, pass either `snapshot_from_id` or `snapshot_from_timestamp` (the two are mutually exclusive). Use `iceberg_snapshots` to list the available snapshots:

```
-- Read a specific snapshot by id
SELECT count(*)
FROM iceberg_scan('data/iceberg/lineitem_iceberg', snapshot_from_id = 7635660646343998149);

-- Read the snapshot that was current at a given time
SELECT count(*)
FROM iceberg_scan('data/iceberg/lineitem_iceberg', snapshot_from_timestamp = TIMESTAMP '2023-02-15
15:08:00');
```

Limitations of Direct Reads

- A version hint or explicit `version` is required to read a table, unless version guessing is enabled.
- Only `gzip`-compressed metadata is supported (via `metadata_compression_codec = 'gzip'`).

Catalog Managed Tables

For full read and write access — and to use Iceberg's catalog features — attach an Iceberg REST catalog. Most catalogs authenticate with OAuth2; store the credentials in a secret and attach the catalog with `ATTACH ... (TYPE iceberg, ...)`:

```
CREATE SECRET iceberg_secret (
    TYPE iceberg,
    CLIENT_ID '<admin>',
    CLIENT_SECRET '<password>',
    OAUTH2_SERVER_URI '<https://catalog.example.com/v1/oauth/tokens>'
);

ATTACH '<warehouse>' AS my_catalog (
    TYPE iceberg,
    SECRET iceberg_secret,
    ENDPOINT '<https://catalog.example.com>'
);
```

Once attached, the catalog behaves like any other DuckDB database: reference its tables as `<catalog>.<schema>.<table>` and query or modify them with regular SQL.

```
SHOW ALL TABLES;

SELECT count(*) FROM my_catalog.default.events;

INSERT INTO my_catalog.default.events VALUES (1, 'click', now());
```

The metadata functions also work on catalog tables when passed a fully qualified name, e.g., `iceberg_snapshots(my_catalog.default.events)`.

- For the full set of write operations — partitioning, `UPDATE`, `DELETE`, `MERGE INTO`, `ALTER TABLE`, and table properties — see Writing to Iceberg.
- For catalog-specific setup and the complete list of `ATTACH` options and secret parameters, see Iceberg REST Catalogs.

Time Travel

On an attached catalog, time travel with the `AT` clause directly on the table:

```
-- Using a snapshot id
SELECT * FROM my_catalog.default.events AT (VERSION => <snapshot_id>);

-- Using a timestamp
SELECT * FROM my_catalog.default.events AT (TIMESTAMP => TIMESTAMP '2025-09-22 12:32:43.217');
```

Interoperability with DuckLake

The `iceberg_to_ducklake` function performs a metadata-only copy of an attached Iceberg catalog into a DuckLake catalog, letting you query Iceberg tables as if they were DuckLake tables:

```
-- With an Iceberg catalog attached as my_catalog
ATTACH 'ducklake:my_ducklake.ducklake' AS my_ducklake;
CALL iceberg_to_ducklake('my_catalog', 'my_ducklake');

-- Skip specific tables
CALL iceberg_to_ducklake('my_catalog', 'my_ducklake', skip_tables := ['table_to_skip']);
```

Writing to Iceberg

The `iceberg` extension supports writing to Iceberg tables that are managed by an Iceberg REST Catalog. All write operations go through the attached catalog and are committed as new Iceberg snapshots.

> Writing requires an attached catalog. The path-based `iceberg_scan` interface described in the overview is read-only. To write, first attach an Iceberg REST catalog.

The examples below assume a catalog has been attached as `my_catalog`.

Creating Schemas and Tables

Iceberg namespaces are exposed as schemas. You can create and drop schemas and tables with standard SQL:

```
CREATE SCHEMA my_catalog.sales;
USE my_catalog.sales;

CREATE TABLE my_catalog.sales.events (
    id INTEGER,
    event_name VARCHAR,
    event_time TIMESTAMP
);

-- Create a table from a query
CREATE TABLE my_catalog.sales.events_copy AS
    FROM my_catalog.sales.events;

DROP TABLE my_catalog.sales.events_copy;
```

Partitioning

Tables can be partitioned with the `PARTITIONED BY` clause using the Iceberg partition transforms:

Transform	Description
`<column>{:.language-sql .highlight}`	Identity – partition by the column value directly.
`year(<column>){:.language-sql .highlight}`, `month(<column>){:.language-sql .highlight}`, `day(<column>){:.language-sql .highlight}`, `hour(<column>){:.language-sql .highlight}`	Partition by a date/timestamp component.
`bucket(<n>, <column>){:.language-sql .highlight}`	Hash the column into n buckets.
`truncate(<n>, <column>){:.language-sql .highlight}`	Truncate the column value to width n.

```
CREATE TABLE my_catalog.sales.events (
    id INTEGER,
    event_name VARCHAR,
    event_time TIMESTAMP
)
PARTITIONED BY (day(event_time), bucket(16, id));
```

The partition spec can be changed on an existing table with `ALTER TABLE ... SET PARTITIONED BY`:

```
ALTER TABLE my_catalog.sales.events SET PARTITIONED BY (month(event_time));
```

> The `write.target-file-size-bytes` and `write.parquet.row-group-size-bytes` table properties are not honored for partitioned tables and raise an error. Set `ignore_target_file_size_for_partitioned_tables` or `ignore_row_group_size_for_partitioned_tables` to `true` to ignore them instead.

Table Properties

Iceberg table properties can be set at creation time with a `WITH` clause. The `format-version` and `location` keys are recognized specially; any other key-value pairs are stored as table properties:

```
CREATE TABLE my_catalog.sales.events (a INTEGER)
WITH (
    'format-version' = '2',                 -- Iceberg format version (2 or 3)
    'location' = 's3://my-bucket/events',   -- base location for the table's data
    'my.custom.property' = 'value'
);
```

Existing properties can be inspected and modified with the property functions:

```
-- View properties
SELECT * FROM iceberg_table_properties(my_catalog.sales.events);

-- Set properties
CALL set_iceberg_table_properties(
    my_catalog.sales.events,
    MAP {'write.update.mode': 'merge-on-read', 'write.delete.mode': 'merge-on-read'}
);

-- Remove properties
CALL remove_iceberg_table_properties(my_catalog.sales.events, ['my.custom.property']);
```

See the Functions and Settings Reference for the equivalent schema (namespace) property functions.

Inserting Data

```
INSERT INTO my_catalog.sales.events
VALUES (1, 'click', TIMESTAMP '2026-06-01 10:00:00');

-- Insert the result of a query
INSERT INTO my_catalog.sales.events
    SELECT * FROM source_table;

-- Match columns by name rather than position
INSERT INTO my_catalog.sales.events BY NAME
    SELECT event_time, id, event_name FROM source_table;
```

Updating and Deleting

```
UPDATE my_catalog.sales.events SET event_name = 'view' WHERE id = 1;

DELETE FROM my_catalog.sales.events WHERE event_time < TIMESTAMP '2026-01-01';
```

UPDATE and DELETE are supported on both partitioned and unpartitioned tables. They use **merge-on-read** semantics and write **positional delete** files; see Limitations.

Merging Data

`MERGE INTO` performs an upsert against a source relation. The join key is given with a second `USING` clause (see the `MERGE INTO` statement):

```
MERGE INTO my_catalog.sales.events AS target
USING new_events AS source USING (id)
WHEN MATCHED THEN UPDATE SET event_name = source.event_name
WHEN NOT MATCHED THEN INSERT VALUES (source.id, source.event_name, source.event_time);
```

Evolving the Schema

The following `ALTER TABLE` operations are supported:

```
ALTER TABLE my_catalog.sales.events ADD COLUMN source VARCHAR DEFAULT 'web';
ALTER TABLE my_catalog.sales.events DROP COLUMN source;
ALTER TABLE my_catalog.sales.events RENAME COLUMN id TO event_id;
ALTER TABLE my_catalog.sales.events ALTER COLUMN event_id TYPE BIGINT;
ALTER TABLE my_catalog.sales.events RENAME TO event_log;
ALTER TABLE my_catalog.sales.events ALTER COLUMN event_id SET DEFAULT 0;
ALTER TABLE my_catalog.sales.events ALTER COLUMN event_id DROP DEFAULT;
```

Copying Between DuckDB and Iceberg

Because the full DDL and DML set is supported, `COPY FROM DATABASE` can perform deep copies between Iceberg and DuckDB storage in either direction:

```
COPY FROM DATABASE duckdb_db TO my_catalog;
COPY FROM DATABASE my_catalog TO duckdb_db;
```

To copy an Iceberg catalog into DuckLake, see Interoperability with DuckLake.

Limitations

- UPDATE and DELETE write **positional deletes** only; copy-on-write is not supported.
- UPDATE and DELETE only support **merge-on-read** semantics. If a table sets `write.update.mode` or `write.delete.mode` to anything other than `merge-on-read`, the operation fails.
- The `write.target-file-size-bytes` and `write.parquet.row-group-size-bytes` table properties are not honored for partitioned tables (see Partitioning).

Iceberg REST Catalogs

This page covers connecting to Iceberg REST Catalogs: authentication, the full set of `ATTACH` options, and setup instructions for specific catalogs. For the basics of attaching a catalog and querying it, see Catalog Managed Tables; for write operations, see Writing to Iceberg.

If you are attaching to an Iceberg REST Catalog managed by Amazon, please see the instructions for attaching to Amazon S3 Tables or Amazon SageMaker Lakehouse.

For all other Iceberg REST Catalogs, you can follow the instructions below. Please see the Examples section for questions about specific catalogs.

Most Iceberg REST Catalogs authenticate via OAuth2. You can use the existing DuckDB secret workflow to store login credentials for the OAuth2 service.

```
CREATE SECRET iceberg_secret (
    TYPE iceberg,
    CLIENT_ID '<admin>',
    CLIENT_SECRET '<password>',
    OAUTH2_SERVER_URI '<http://iceberg_rest_catalog_url.com/v1/oauth/tokens>'
);
```

If you already have a Bearer token, you can pass it directly to your `CREATE SECRET` statement

```
CREATE SECRET iceberg_secret (
    TYPE iceberg,
    TOKEN '<bearer_token>'
);
```

You can attach the Iceberg catalog with the following `ATTACH` statement.

```
LOAD httpfs;
ATTACH '<warehouse>' AS iceberg_catalog (
   TYPE iceberg,
   SECRET iceberg_secret, -- pass a specific secret name to prevent ambiguity
   ENDPOINT '<https://rest_endpoint.com>'
);
```

To see the available tables run

```
SHOW ALL TABLES;
```

ATTACH Options

A REST Catalog with OAuth2 authorization can also be attached with just an `ATTACH` statement. See the complete list of `ATTACH` options for a REST Catalog below.

Parameter	Type	Default	Description
`ENDPOINT_TYPE`	`VARCHAR`	`NULL`	Used for attaching S3 Tables or Glue catalogs. Allowed values are `GLUE` and `S3_TABLES`.
`ENDPOINT`	`VARCHAR`	`NULL`	URL endpoint to communicate with the REST Catalog. Cannot be used in conjunction with `ENDPOINT_TYPE`.
`SECRET`	`VARCHAR`	`NULL`	Name of secret used to communicate with the REST Catalog.
`CLIENT_ID`	`VARCHAR`	`NULL`	`CLIENT_ID` used for Secret.
`CLIENT_SECRET`	`VARCHAR`	`NULL`	`CLIENT_SECRET` needed for Secret.
`DEFAULT_REGION`	`VARCHAR`	`NULL`	A Default region to use when communicating with the storage layer.
`OAUTH2_SERVER_URI`	`VARCHAR`	`NULL`	OAuth2 server url for getting a Bearer Token.
`AUTHORIZATION_TYPE`	`VARCHAR`	`OAUTH2`	Pass `SigV4` for Catalogs the require SigV4 authorization, `none` for catalogs that don't need authentication.
`ACCESS_DELEGATION_MODE`	`VARCHAR`	`vended_credentials`	Access delegation mode. Allowed values are `vended_credentials` and `none`.
`EXTRA_HTTP_HEADERS`	`MAP`	`NULL`	Additional HTTP headers to send with REST Catalog requests.

Parameter	Type	Default	Description
SUPPORT_NESTED_NAMESPACES	BOOLEAN	true	Option for catalogs that support nested namespaces.
STAGE_CREATE_TABLES	BOOLEAN	true	Controls whether DuckDB uses staged CREATE TABLE. Disable for catalogs that do not support staged table creation.
DISABLE_MULTI_TABLE_COMMIT	BOOLEAN	false	Disables the multi-table transactions/commit endpoint. Enable for catalogs that reject this endpoint.
SKIP_CREATE_TABLE_METADATA_UPDATES	BOOLEAN	false	Skips follow-up metadata updates after non-staged CREATE TABLE. Enable for catalogs that fully initialize metadata during table creation and reject subsequent updates.
REMOVE_FILES_ON_DELETE	BOOLEAN	true	Controls whether DuckDB removes storage files when a table is dropped.
MAX_TABLE_STALENESS	INTERVAL	NULL	Option for preventing unnecessary requests to the Iceberg REST Catalog. You can pass human readable interval strings. `10 minutes`, `30 seconds`, `1 year` all work.
PURGE_REQUESTED	BOOLEAN	true	Option to send the PurgeRequested parameter when dropping a table.
SUPPORT_NESTED_NAMESPACES	BOOLEAN	false	Set to `true` for catalogs that support nested namespaces.
SUPPORT_STAGE_CREATE	BOOLEAN	true	Set to `false` for catalogs that do not support stage create.
DEFAULT_SCHEMA	VARCHAR	NULL	The default schema (namespace) to use for the attached catalog.
ENCODE_ENTIRE_PREFIX	BOOLEAN	false	URL-encode the entire path prefix when communicating with the catalog.
MAX_TABLE_STALENESS	INTERVAL	NULL	Option for preventing unnecessary requests to the Iceberg REST Catalog. You can pass human readable interval strings. `10 minutes`, `30 seconds`, `1 year` all work.
PURGE_REQUESTED	BOOLEAN	false	Option to send the PurgeRequested parameter when dropping a table.

The following options can only be passed to a `CREATE SECRET` statement and they require `AUTHORIZATION_TYPE` to be `OAUTH2`:

Parameter	Type	Default	Description
OAUTH2_GRANT_TYPE	VARCHAR	NULL	Grant Type when requesting an OAuth Token.
OAUTH2_SCOPE	VARCHAR	NULL	Requested scope for the returned OAuth Access Token.

Working with an Attached Catalog

Once a catalog is attached, you can run the full set of read and write operations against its tables:

- **Reading and metadata**: `SELECT`, time travel with the `AT` clause, and the `iceberg_metadata`, `iceberg_snapshots`, and statistics functions. See the Functions and Settings Reference.
- **Writing**: `CREATE`/`DROP SCHEMA` and `TABLE`, partitioning, `INSERT`, `UPDATE`, `DELETE`, `MERGE INTO`, `ALTER TABLE`, table properties, and `COPY FROM DATABASE`. See Writing to Iceberg.

Metadata functions accept a fully qualified table name, e.g.:

```
SELECT * FROM iceberg_snapshots(my_catalog.default.t);
```

Specific Catalog Examples

Cloudflare R2 Catalog

To attach to an R2 Cloudflare managed catalog follow the attach steps below.

```
CREATE SECRET r2_secret (
    TYPE iceberg,
    TOKEN '<r2_token>'
);
```

You can create a token by following the create an API token steps in getting started. Then, attach the catalog with the following commands.

```
ATTACH '<warehouse>' AS my_r2_catalog (
    TYPE iceberg,
    ENDPOINT '<catalog-uri>'
);
```

The variables for `warehouse` and `catalog-uri` are available under the settings of the R2 Object Storage Catalog (R2 Object Store, Catalog name, Settings).

Once you attached to the R2 Data Catalog, create a schema. You can set it as default with the USE command:

```
CREATE SCHEMA my_r2_catalog.my_schema;
USE my_r2_catalog.my_schema;
```

Polaris

To attach to a Polaris catalog, use the following commands:

```
CREATE SECRET polaris_secret (
    TYPE iceberg,
    CLIENT_ID '<admin>',
    CLIENT_SECRET '<password>',
);

ATTACH 'quickstart_catalog' AS polaris_catalog (
    TYPE iceberg,
    ENDPOINT '<polaris_rest_catalog_endpoint>',
    ACCESS_DELEGATION_MODE 'vended_credentials'
);
```

Lakekeeper

To attach to a Lakekeeper catalog the following commands will work.

```
CREATE SECRET lakekeeper_secret (
    TYPE iceberg,
    CLIENT_ID '<admin>',
    CLIENT_SECRET '<password>',
    OAUTH2_SCOPE '<scope>',
    OAUTH2_SERVER_URI '<lakekeeper_oauth_url>'
);
```

```
ATTACH '<warehouse>' AS lakekeeper_catalog (
    TYPE iceberg,
    ENDPOINT '<lakekeeper_irc_url>',
    SECRET '<lakekeeper_secret>'
);
```

Google Cloud BigLake

To attach to a Google Cloud BigLake catalog, you can use extra HTTP headers to specify the GCP project for billing purposes.

First, get your Google Cloud access token:

```
gcloud auth application-default print-access-token
```

Then create a secret with the token and extra headers:

```
CREATE SECRET biglake_secret (
    TYPE iceberg,
    TOKEN '<your_access_token>',
    EXTRA_HTTP_HEADERS MAP {
        'x-goog-user-project': '<your_gcp_project_id>'
    }
);
```

Attach to the BigLake catalog:

```
ATTACH '<gs://your-biglake-bucket>' AS biglake_catalog (
    TYPE iceberg,
    ENDPOINT 'https://biglake.googleapis.com/iceberg/v1/restcatalog',
    SECRET biglake_secret
);
```

Example using the BigLake public dataset:

```
CREATE SECRET biglake_public_secret (
    TYPE iceberg,
    TOKEN '<your_access_token>',
    EXTRA_HTTP_HEADERS MAP {
        'x-goog-user-project': '<your_gcp_project_id>'
    }
);

ATTACH 'gs://biglake-public-nyc-taxi-iceberg' AS biglake_public (
    TYPE iceberg,
    ENDPOINT 'https://biglake.googleapis.com/iceberg/v1/restcatalog',
    SECRET biglake_public_secret
);

-- Query the data
SELECT count(*) FROM biglake_public.public_data.nyc_taxicab;
```

> **Note.**: Google Cloud access tokens expire after 1 hour. For long-running sessions, you'll need to refresh the token periodically.

Catalogs with Limited REST Spec Support

Some catalogs implement a subset of the Iceberg REST Catalog specification. Use the compatibility options below to adjust DuckDB's behavior for these catalogs.

Catalog behavior	Option to set
Does not support staged CREATE TABLE	`STAGE_CREATE_TABLES false`
Rejects the multi-table transactions/commit endpoint	`DISABLE_MULTI_TABLE_COMMIT true`
Fully initializes metadata on CREATE TABLE and rejects follow-up metadata updates	`SKIP_CREATE_TABLE_METADATA_UPDATES true`
Does not allow DuckDB to remove storage files on DROP TABLE	`REMOVE_FILES_ON_DELETE false`

For example, to attach a Unity Catalog Horizon endpoint that does not support staged creates, rejects the transactions/commit endpoint, and manages its own metadata and storage cleanup:

```
ATTACH '<warehouse>' AS horizon_catalog (
    TYPE iceberg,
    ENDPOINT '<catalog_endpoint>',
    STAGE_CREATE_TABLES false,
    DISABLE_MULTI_TABLE_COMMIT true,
    SKIP_CREATE_TABLE_METADATA_UPDATES true,
    REMOVE_FILES_ON_DELETE false
);
```

Limitations

DuckDB supports Iceberg REST Catalogs backed by S3, S3 Tables, and Google Cloud Storage (GCS). Support for other storage backends is not yet available.

Functions and Settings Reference

This page is a reference for all functions and settings provided by the `iceberg` extension. For task-oriented documentation, see the Overview (reading), Writing to Iceberg, and Iceberg REST Catalogs pages.

Functions that take a table accept either a path to a table's metadata (e.g., `'data/iceberg/lineitem_iceberg'`) or, when a catalog is attached, a fully qualified table name (e.g., `my_catalog.default.my_table`).

Common Parameters

The read and metadata table functions below accept the following named parameters:

Parameter	Type	Default	Description
`allow_moved_paths`	`BOOLEAN`	`false`	Allows scanning Iceberg tables that are moved
`metadata_compression_codec`	`VARCHAR`	`''`	Set to `'gzip'` to read gzip-compressed metadata files

Parameter	Type	Default	Description
`snapshot_from_id`	`UBIGINT`	`NULL`	Access the snapshot with a specific `id`
`snapshot_from_timestamp`	`TIMESTAMP`	`NULL`	Access the snapshot as of a specific `timestamp`
`version`	`VARCHAR`	`'?'`	Explicit version string, hint file, or `'?'` for guessing
`version_name_format`	`VARCHAR`	`'v%s%s.metadata.json,%s%s.metadata.json'`	Controls how versions are converted to metadata file names

See Selecting Metadata Versions for details.

Read and Metadata Functions

Function	Description
`iceberg_scan(table, <options>)`	Reads the data of an Iceberg table. Returns the table's columns.
`iceberg_metadata(table, <options>)`	Returns one row per manifest entry. Columns: `manifest_path`, `manifest_sequence_number`, `manifest_content`, `status`, `content`, `file_path`, `file_format`, `record_count`.
`iceberg_snapshots(table, <options>)`	Returns one row per snapshot. Columns: `sequence_number`, `snapshot_id`, `timestamp_ms`, `manifest_list`.
`iceberg_column_stats(table, <options>)`	Returns per-data-file, per-column statistics. Columns include `file_path`, `column_name`, `column_type`, `lower_bound`, `upper_bound`, `value_count`, `null_value_count`, `nan_value_count`.
`iceberg_partition_stats(table, <options>)`	Returns per-partition-field statistics. Columns include `partition_field_name`, `partition_source_columns`, `partition_field_transform`, `lower_bound`, `upper_bound`.
`iceberg_load_table_response(table)`	Advanced, REST-catalog only. Returns the raw catalog `LoadTable` response: `metadata_location`, `metadata` (`VARIANT`), `config` (`MAP`), `storage_credentials`, `request_url`.

```
SELECT * FROM iceberg_snapshots('data/iceberg/lineitem_iceberg');
SELECT * FROM iceberg_column_stats('my_catalog.default.events');
```

Table and Schema Property Functions

These functions read and modify Iceberg table properties and Iceberg schema (namespace) properties. They require an attached catalog. See Writing to Iceberg.

Function	Description
`iceberg_table_properties(table)`	Returns all properties of the table.
`set_iceberg_table_properties(table, properties)`	Sets properties on the table. `properties` is a `MAP(VARCHAR, VARCHAR)`.

Function	Description
`remove_iceberg_table_properties(table, property_list)`	Removes the listed properties (`VARCHAR[]`) from the table.
`iceberg_schema_properties(schema)`	Returns all properties of the schema (namespace).
`set_iceberg_schema_properties(schema, properties)`	Sets properties on the schema.
`remove_iceberg_schema_properties(schema, property_list)`	Removes the listed properties from the schema.

DuckLake Interoperability

Function	Description
`iceberg_to_ducklake(iceberg_catalog, ducklake_catalog, skip_tables := [...])`	Performs a metadata-only copy of an attached Iceberg catalog into a DuckLake catalog. The optional `skip_tables` parameter (`VARCHAR[]`) excludes tables.

See Interoperability with DuckLake.

Partition Transform Functions

These scalar functions implement the Iceberg partition transforms. They are most often used in a `PARTITIONED BY` clause (see Partitioning), but can also be called directly.

Function	Description
`iceberg_bucket(num_buckets, value)`	Returns the Iceberg bucket partition value (an `INTEGER`) for `value`. Supported `value` types: `INTEGER`, `BIGINT`, `DECIMAL`, `DATE`, `TIME`, `TIMESTAMP`, `TIMESTAMP WITH TIME ZONE`, `TIMESTAMP_NS`, `VARCHAR`, `BLOB`, `UUID`.
`iceberg_truncate(width, value)`	Returns the Iceberg truncate partition value for `value`, with the same type as `value`. Supported types: `INTEGER`, `BIGINT`, `DECIMAL`, `VARCHAR`, `BLOB`.

```
SELECT iceberg_bucket(16, 'duckdb');
SELECT iceberg_truncate(10, 1234);
```

Settings

Setting	Type	Default	Description
`unsafe_enable_version_guessing`	`BOOLEAN`	`false`	Enable globbing the filesystem (if possible) to find the latest metadata version. This may read an uncommitted version, so it is disabled by default.
`iceberg_use_metadata_log`	`BOOLEAN`	`true`	Use a table's optional `metadata-log` to preserve atomicity guarantees, at the cost of an additional metadata GET in rare cases.
`ignore_target_file_size_for_partitioned_tables`	`BOOLEAN`	`false`	Ignore the unsupported `write.target-file-size-bytes` table property on partitioned tables instead of raising an error.
`ignore_row_group_size_for_partitioned_tables`	`BOOLEAN`	`false`	Ignore the unsupported `write.parquet.row-group-size-bytes` table property on partitioned tables instead of raising an error.
`iceberg_via_aws_sdk_for_catalog_interactions`	`BOOLEAN`	`false`	Use the legacy AWS SDK code path to interact with AWS-based catalogs instead of DuckDB's HTTP client.

Amazon S3 Tables

> Support for S3 Tables is currently experimental.

The `iceberg` extension supports reading Iceberg tables stored in Amazon S3 Tables.

Requirements

Install the following extensions:

```
INSTALL aws;
INSTALL httpfs;
INSTALL iceberg;
```

Connecting to Amazon S3 Tables

You can let DuckDB detect your AWS credentials and configuration based on the default profile in your `~/.aws` directory by creating the following secret using the Secrets Manager:

```
CREATE SECRET (
    TYPE s3,
    PROVIDER credential_chain
);
```

Alternatively, you can set the values manually:

```
CREATE SECRET (
    TYPE s3,
    KEY_ID '<key_id>',
    SECRET '<secret>',
    REGION '<region>'
);
```

Then, connect to the catalog using your S3 Tables ARN (available in the AWS Management Console) and the `ENDPOINT_TYPE s3_tables` option:

```
ATTACH '<s3_tables_arn>' AS my_s3_tables_catalog (
   TYPE iceberg,
   ENDPOINT_TYPE s3_tables
);
```

> **Warning.** `ENDPOINT_TYPE s3_tables` always builds an endpoint of the form `s3tables.<region>.amazonaws.com/iceberg`. This is incorrect for any region whose endpoint does not use the plain `amazonaws.com` suffix — most notably the AWS China regions (`cn-north-1`, `cn-northwest-1`), which use `amazonaws.com.cn`. For such regions, attach the catalog by passing an explicit `ENDPOINT` (with the correct host for your region) together with `AUTHORIZATION_TYPE 'sigv4'`, instead of using `ENDPOINT_TYPE`.

To check whether the attachment worked, list all tables:

```
SHOW ALL TABLES;
```

You can query a table as follows:

```
SELECT count(*)
FROM my_s3_tables_catalog.<namespace_name>.<table_name>;
```

Amazon SageMaker Lakehouse (AWS Glue)

> Support for Amazon SageMaker Lakehouse (AWS Glue) is currently experimental.

The `iceberg` extension supports reading Iceberg tables through the Amazon SageMaker Lakehouse (a.k.a. AWS Glue) catalog.

Requirements

To use it, install the following extensions:

```
INSTALL aws;
INSTALL httpfs;
INSTALL iceberg;
```

> If you want to switch back to using extensions from the `core` repository, follow the extension documentation.

Connecting to Amazon SageMaker Lakehouse (AWS Glue)

Create an S3 secret using the Secrets Manager:

```
CREATE SECRET (
    TYPE s3,
    PROVIDER credential_chain,
    CHAIN sts,
    ASSUME_ROLE_ARN 'arn:aws:iam::<account_id>:role/<role>',
    REGION 'us-east-2'
);
```

In this example we use an STS token, but other authentication methods are supported.

Then, connect to the catalog:

```
ATTACH '<account_id>' AS glue_catalog (
    TYPE iceberg,
    ENDPOINT 'glue.<REGION>.amazonaws.com/iceberg',
    AUTHORIZATION_TYPE 'sigv4'
);
```

Or alternatively:

```
ATTACH '<account_id>' AS glue_catalog (
    TYPE iceberg,
    ENDPOINT_TYPE 'glue'
);
```

To check whether the attachment worked, list all tables:

```
SHOW ALL TABLES;
```

You can query a table as follows:

```
SELECT count(*)
FROM glue_catalog.<namespace_name>.<table_name>;
```

If you have an S3 Tables federated catalog, you can create a table using the standard `CREATE TABLE` syntax;

```
CREATE TABLE glue_catalog.<namespace_name>.<table_name> (a INTEGER, b VARCHAR);
```

If the catalog is not federated by S3 Tables, you may need to create pass a `location` table property. You can do so using the `WITH` clause.

```
CREATE TABLE glue_catalog.<namespace_name>.<table_name> (a INTEGER, b VARCHAR)
WITH (
    'location' = 's3://path/to/location'
);
```

You can learn more about the `WITH` clause at Table Properties.

Troubleshooting

Curl Request Fails

Problem

When trying to attach to an Iceberg REST Catalog endpoint, DuckDB returns the following error:

```
IO Error:
Curl Request to '/v1/oauth/tokens' failed with error: 'URL using bad/illegal format or missing URL'
```

Solution

Make sure that you have the latest Iceberg extension installed:

```
duckdb
```

```
FORCE INSTALL iceberg FROM core_nightly;
```

Exit DuckDB and start a new session:

```
duckdb
```

```
LOAD iceberg;
```

HTTP Error 403

Problem

When trying to list the tables in a remote-attached catalog, DuckDB returns the following error:

```
SHOW ALL TABLES;
```

```
Failed to query https://s3tables.us-east-2.amazonaws.com/iceberg/v1/arn:aws:s3tables:... http error 403 thrown.
Message: {"message":"The security token included in the request is invalid."}
```

Solution

Use the `duckdb_secrets()` function to check whether DuckDB loaded the required credentials:

```
.mode line
FROM duckdb_secrets();
```

If you do not see your credentials, set them manually using the following secret:

```
CREATE SECRET (
    TYPE s3,
    KEY_ID '<AKIAIOSFODNN7EXAMPLE>',
    SECRET '<wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY>',
    REGION '<us-east-1>'
);
```

ICU Extension

The `icu` extension contains an easy-to-use version of the collation/timezone part of the ICU library.

Installing and Loading

The `icu` extension will be transparently autoloaded on first use from the official extension repository. If you would like to install and load it manually, run:

```
INSTALL icu;
LOAD icu;
```

Features

The `icu` extension introduces the following features:

- Region-dependent collations
- Time zones, used for timestamp data types and timestamp functions

inet Extension

The `inet` extension defines the `INET` data type for storing IPv4 and IPv6 Internet addresses. It supports the CIDR notation for subnet masks (e.g., `198.51.100.0/22`, `2001:db8:3c4d::/48`).

Installing and Loading

The `inet` extension will be transparently autoloaded on first use from the official extension repository. If you would like to install and load it manually, run:

```
INSTALL inet;
LOAD inet;
```

Examples

```
SELECT '127.0.0.1'::INET AS ipv4, '2001:db8:3c4d::/48'::INET AS ipv6;
```

ipv4	ipv6
127.0.0.1	2001:db8:3c4d::/48

```
CREATE TABLE tbl (id INTEGER, ip INET);
INSERT INTO tbl VALUES
    (1, '192.168.0.0/16'),
    (2, '127.0.0.1'),
    (3, '8.8.8.8'),
    (4, 'fe80::/10'),
    (5, '2001:db8:3c4d:15::1a2f:1a2b');
SELECT * FROM tbl;
```

id	ip
1	192.168.0.0/16
2	127.0.0.1
3	8.8.8.8
4	fe80::/10
5	2001:db8:3c4d:15::1a2f:1a2b

Operations on `INET` Values

`INET` values can be compared naturally, and IPv4 will sort before IPv6. Additionally, IP addresses can be modified by adding or subtracting integers.

```
CREATE TABLE tbl (cidr INET);
INSERT INTO tbl VALUES
    ('127.0.0.1'::INET + 10),
    ('fe80::10'::INET - 9),
    ('127.0.0.1'),
    ('2001:db8:3c4d:15::1a2f:1a2b');
SELECT cidr FROM tbl ORDER BY cidr ASC;
```

cidr
127.0.0.1
127.0.0.11
2001:db8:3c4d:15::1a2f:1a2b
fe80::7

`host` Function

The host component of an `INET` value can be extracted using the `HOST()` function.

```
CREATE TABLE tbl (cidr INET);
INSERT INTO tbl VALUES
    ('192.168.0.0/16'),
    ('127.0.0.1'),
    ('2001:db8:3c4d:15::1a2f:1a2b/96');
SELECT cidr, host(cidr) AS host FROM tbl;
```

cidr	host
192.168.0.0/16	192.168.0.0
127.0.0.1	127.0.0.1
2001:db8:3c4d:15::1a2f:1a2b/96	2001:db8:3c4d:15::1a2f:1a2b

`netmask` Function

Computes the network mask for the address's network.

```
CREATE TABLE tbl (cidr INET);
INSERT INTO tbl VALUES
    ('192.168.1.5/24'),
    ('127.0.0.1'),
    ('2001:db8:3c4d:15::1a2f:1a2b/96');
SELECT cidr, netmask(cidr) AS netmask FROM tbl;
```

cidr	netmask
192.168.1.5/24	255.255.255.0/24
127.0.0.1	255.255.255.255
2001:db8:3c4d:15::1a2f:1a2b/96	ffff:ffff:ffff:ffff:ffff:ffff::/96

`network` Function

Returns the network part of the address, zeroing out whatever is to the right of the netmask.

```
CREATE TABLE tbl (cidr INET);
INSERT INTO tbl VALUES
    ('192.168.1.5/24'),
    ('127.0.0.1'),
    ('2001:db8:3c4d:15::1a2f:1a2b/96');
SELECT cidr, network(cidr) AS network FROM tbl;
```

cidr	network
192.168.1.5/24	192.168.1.0/24
127.0.0.1	127.0.0.1
2001:db8:3c4d:15::1a2f:1a2b/96	2001:db8:3c4d:15::/96

`broadcast` Function

Computes the broadcast address for the address's network.

```
CREATE TABLE tbl (cidr INET);
INSERT INTO tbl VALUES
    ('192.168.1.5/24'),
    ('127.0.0.1'),
    ('2001:db8:3c4d:15::1a2f:1a2b/96');
SELECT cidr, broadcast(cidr) AS broadcast FROM tbl;
```

cidr	broadcast
192.168.1.5/24	192.168.1.255/24
127.0.0.1	127.0.0.1
2001:db8:3c4d:15::1a2f:1a2b/96	2001:db8:3c4d:15::ffff:ffff/96

`<<=` Predicate

Is subnet contained by or equal to subnet?

```
CREATE TABLE tbl (cidr INET);
INSERT INTO tbl VALUES
    ('192.168.1.0/24'),
    ('127.0.0.1'),
    ('2001:db8:3c4d:15::1a2f:1a2b/96');
SELECT cidr, INET '192.168.1.5/32' <<= cidr AS subnet_contained FROM tbl;
```

cidr	subnet_contained
192.168.1.0/24	true
127.0.0.1	false
2001:db8:3c4d:15::1a2f:1a2b/96	false

>>= Predicate

Does subnet contain or equal subnet?

```
CREATE TABLE tbl (cidr INET);
INSERT INTO tbl VALUES
    ('192.168.1.0/24'),
    ('127.0.0.1'),
    ('2001:db8:3c4d:15::1a2f:1a2b/96');
SELECT cidr, INET '192.168.0.0/16' >>= cidr AS subnet_contains FROM tbl;
```

cidr	subnet_contains
192.168.1.0/24	true
127.0.0.1	false
2001:db8:3c4d:15::1a2f:1a2b/96	false

HTML Escape and Unescape Functions

```
SELECT html_escape('&');
```

html_escape('&')
varchar
&

```
SELECT html_unescape('&amp;');
```

html_unescape('&')
varchar
&

jemalloc Extension

The `jemalloc` extension replaces the system's memory allocator with jemalloc. Unlike other DuckDB extensions, the `jemalloc` extension is statically linked and cannot be installed or loaded during runtime.

Operating System Support

The availability of the `jemalloc` extension depends on the operating system.

Linux

Linux distributions of DuckDB ship with the `jemalloc` extension. To disable the `jemalloc` extension, build DuckDB from source and set the `SKIP_EXTENSIONS` flag as follows:

```
GEN=ninja SKIP_EXTENSIONS="jemalloc" make
```

macOS

The macOS version of DuckDB does not ship with the `jemalloc` extension but can be built from source to include it:

```
GEN=ninja BUILD_JEMALLOC=1 make
```

Windows

On Windows, this extension is not available.

Configuration

Environment Variables

The jemalloc allocator in DuckDB can be configured via the `DUCKDB_JE_MALLOC_CONF` environment variable. Setting this is equivalent to setting the `MALLOC_CONF` environment variable for jemalloc but DuckDB uses a different environment variable name to avoid potential name clashes with other applications.

Background Threads

By default, jemalloc's background threads are disabled. To enable them, use the following configuration option:

```
SET allocator_background_threads = true;
```

Background threads asynchronously purge outstanding allocations so that this doesn't have to be done synchronously by the foreground threads. This improves allocation performance, and should be noticeable in allocation-heavy workloads, especially on many-core CPUs.

Lance Extension

The `lance` extension adds support for reading and writing Lance tables. Lance is a modern lakehouse format optimized for ML/AI workloads, with native cloud storage support.

Installing and Loading

You can install the `lance` extension from DuckDB's core extensions repository and load it using the following commands:

```
INSTALL lance;
LOAD lance;
```

Usage

- Full SQL reference
- Cloud storage reference

Query a Lance Dataset

Local file:

```
SELECT *
FROM '<path/to/dataset.lance>'
LIMIT 10;
```

S3:

```
SELECT *
FROM 's3://<bucket/path/to/out.lance>'
LIMIT 10;
```

To access object store URIs (e.g., `s3://...`), configure a `TYPE lance` secret using the Secrets Manager:

```
CREATE SECRET (
    TYPE lance,
    PROVIDER credential_chain,
    SCOPE 's3://bucket/'
);

SELECT *
FROM 's3://<bucket/path/to/out.lance>'
LIMIT 10;
```

Write a Lance Dataset

Use the `COPY ... TO ...` statement to materialize query results as a Lance dataset.

```
-- Create/overwrite a Lance dataset from a query
COPY (
    SELECT 1::BIGINT AS id, 'a'::VARCHAR AS s
    UNION ALL
    SELECT 2::BIGINT AS id, 'b'::VARCHAR AS s
) TO '<path/to/dataset.lance>' (
    FORMAT lance,
    MODE 'overwrite'
);

-- Read it back via the replacement scan
SELECT count(*) FROM '<path/to/dataset.lance>';

-- Append more rows to an existing dataset
COPY (
    SELECT 3::BIGINT AS id, 'c'::VARCHAR AS s
) TO '<path/to/dataset.lance>' (
    FORMAT lance,
    MODE 'append'
);

-- Optionally create an empty dataset (schema only)
COPY (
    SELECT 1::BIGINT AS id, 'x'::VARCHAR AS s
    WITH NO DATA
) TO 'path/to/empty.lance' (
    FORMAT lance,
    MODE 'overwrite',
    WRITE_EMPTY_FILE true
);
```

To write to `s3://...` paths, configure a `TYPE lance` secret for that scope using the Secrets Manager:

```
CREATE SECRET (
    TYPE lance,
    PROVIDER credential_chain,
    SCOPE 's3://<bucket>/'
);

COPY (SELECT 1 AS id)
TO 's3://<bucket/path/to/out.lance>'
(FORMAT lance, MODE 'overwrite');
```

Create a Lance Dataset via CREATE TABLE (Directory Namespace)

When you ATTACH a directory as a Lance namespace, you can create new datasets using `CREATE TABLE` (schema-only) or `CREATE TABLE AS SELECT` (CTAS). The dataset is written to `<namespace_root>/<table_name.lance>`{:.language-sql .highlight}.

```
ATTACH '<path/to/dir>' AS lance_ns (TYPE lance);

-- Schema-only (creates an empty dataset)
CREATE TABLE lance_ns.main.my_empty (id BIGINT, s VARCHAR);

-- CTAS (writes query results)
CREATE TABLE lance_ns.main.my_dataset AS
    SELECT 1::BIGINT AS id, 'a'::VARCHAR AS s
    UNION ALL
    SELECT 2::BIGINT AS id, 'b'::VARCHAR AS s;

SELECT count(*) FROM lance_ns.main.my_dataset;
```

Vector Search

```
-- Search a vector column, returning distances in `_distance` (smaller is closer)
SELECT id, label, _distance
FROM lance_vector_search(
    '<path/to/dataset.lance>', 'vec',
    [0.1, 0.2, 0.3, 0.4]::FLOAT[4],
    k = 5,
    prefilter = true
)
ORDER BY _distance ASC;
```

See the SQL reference for full parameter documentation.

Full-Text Search (FTS)

```
-- Search a text column, returning BM25-like scores in `_score`
SELECT id, text, _score
FROM lance_fts(
    '<path/to/dataset.lance>',
    'text',
    'puppy',
    k = 10,
    prefilter = true
)
ORDER BY _score DESC;
```

See the SQL reference for full parameter documentation.

Hybrid Search (Vector + FTS)

```
-- Combine vector and text scores, returning `_hybrid_score` in addition to `_distance` / `_score`
SELECT id, _hybrid_score, _distance, _score
FROM lance_hybrid_search('<path/to/dataset.lance>',
                         'vec', [0.1, 0.2, 0.3, 0.4]::FLOAT[4],
                         'text', 'puppy',
                         k = 10, prefilter = false,
                         alpha = 0.5, oversample_factor = 4)
ORDER BY _hybrid_score DESC;
```

Limitations

The `lance` extension is currently available for the following platforms:

- `linux_amd64`
- `linux_arm64`
- `osx_arm64`
- `windows_amd64`

MySQL Extension

The `mysql` extension allows DuckDB to directly read and write data from/to a running MySQL instance. The data can be queried directly from the underlying MySQL database. Data can be loaded from MySQL tables into DuckDB tables, or vice versa.

Installing and Loading

To install the `mysql` extension, run:

```
INSTALL mysql;
```

The extension is loaded automatically upon first use. If you prefer to load it manually, run:

```
LOAD mysql;
```

Reading Data from MySQL

To make a MySQL database accessible to DuckDB use the ATTACH command with the `mysql` or the `mysql_scanner` type:

```
ATTACH 'host=localhost user=root port=0 database=mysql' AS mysqldb (TYPE mysql);
USE mysqldb;
```

Configuration

The connection string determines the parameters for how to connect to MySQL as a set of `key=value` pairs. Any options not provided are replaced by their default values, as per the table below. Connection information can also be specified with environment variables. If no option is provided explicitly, the MySQL extension tries to read it from an environment variable.

Setting	Default	Environment variable
database	NULL	MYSQL_DATABASE
host	localhost	MYSQL_HOST
password		MYSQL_PWD
port	0	MYSQL_TCP_PORT
socket	NULL	MYSQL_UNIX_PORT
user	*current user*	MYSQL_USER
ssl_mode	preferred	
ssl_ca		
ssl_capath		
ssl_cert		
ssl_cipher		
ssl_crl		
ssl_crlpath		

Setting	Default	Environment variable
ssl_key		

Configuring via Secrets

MySQL connection information can also be specified with secrets. The following syntax can be used to create a secret.

```
CREATE SECRET (
    TYPE mysql,
    HOST '127.0.0.1',
    PORT 0,
    DATABASE mysql,
    USER 'mysql',
    PASSWORD ''
);
```

The information from the secret will be used when ATTACH is called. We can leave the connection string empty to use all of the information stored in the secret.

```
ATTACH '' AS mysql_db (TYPE mysql);
```

We can use the connection string to override individual options. For example, to connect to a different database while still using the same credentials, we can override only the database name in the following manner.

```
ATTACH 'database=my_other_db' AS mysql_db (TYPE mysql);
```

By default, created secrets are temporary. Secrets can be persisted using the `CREATE PERSISTENT SECRET` command. Persistent secrets can be used across sessions.

Managing Multiple Secrets Named secrets can be used to manage connections to multiple MySQL database instances. Secrets can be given a name upon creation.

```
CREATE SECRET mysql_secret_one (
    TYPE mysql,
    HOST '127.0.0.1',
    PORT 0,
    DATABASE mysql,
    USER 'mysql',
    PASSWORD ''
);
```

The secret can then be explicitly referenced using the SECRET parameter in the ATTACH.

```
ATTACH '' AS mysql_db_one (TYPE mysql, SECRET mysql_secret_one);
```

SSL Connections

The `ssl` connection parameters can be used to make SSL connections. Below is a description of the supported parameters.

Setting	Description
ssl_mode	The security state to use for the connection to the server: `disabled, required, verify_ca, verify_identity or preferred` (default: `preferred`)
ssl_ca	The path name of the Certificate Authority (CA) certificate file
ssl_capath	The path name of the directory that contains trusted SSL CA certificate files

Setting	Description
ssl_cert	The path name of the client public key certificate file
ssl_cipher	The list of permissible ciphers for SSL encryption
ssl_crl	The path name of the file containing certificate revocation lists
ssl_crlpath	The path name of the directory that contains files containing certificate revocation lists
ssl_key	The path name of the client private key file

Reading MySQL Tables

The tables in the MySQL database can be read as if they were normal DuckDB tables, but the underlying data is read directly from MySQL at query time.

```
SHOW ALL TABLES;
```

name
signed_integers

```
SELECT * FROM signed_integers;
```

t	s	m	i	b
-128	-32768	-8388608	-2147483648	-9223372036854775808
127	32767	8388607	2147483647	9223372036854775807
NULL	NULL	NULL	NULL	NULL

It might be desirable to create a copy of the MySQL databases in DuckDB to prevent the system from re-reading the tables from MySQL continuously, particularly for large tables.

Data can be copied over from MySQL to DuckDB using standard SQL, for example:

```
CREATE TABLE duckdb_table AS FROM mysqlscanner.mysql_table;
```

Writing Data to MySQL

In addition to reading data from MySQL, create tables, ingest data into MySQL and make other modifications to a MySQL database using standard SQL queries.

This allows you to use DuckDB to, for example, export data that is stored in a MySQL database to Parquet, or read data from a Parquet file into MySQL.

Below is a brief example of how to create a new table in MySQL and load data into it.

```
ATTACH 'host=localhost user=root port=0 database=mysqlscanner' AS mysql_db (TYPE mysql);
CREATE TABLE mysql_db.tbl (id INTEGER, name VARCHAR);
INSERT INTO mysql_db.tbl VALUES (42, 'DuckDB');
```

Many operations on MySQL tables are supported. All these operations directly modify the MySQL database, and the result of subsequent operations can then be read using MySQL. Note that if modifications are not desired, ATTACH can be run with the READ_ONLY property which prevents making modifications to the underlying database. For example:

```
ATTACH 'host=localhost user=root port=0 database=mysqlscanner' AS mysql_db (TYPE mysql, READ_ONLY);
```

Supported Operations

Below is a list of supported operations.

CREATE TABLE

```
CREATE TABLE mysql_db.tbl (id INTEGER, name VARCHAR);
```

INSERT INTO

```
INSERT INTO mysql_db.tbl VALUES (42, 'DuckDB');
```

SELECT

```
SELECT * FROM mysql_db.tbl;
```

id	name
42	DuckDB

COPY

```
COPY mysql_db.tbl TO 'data.parquet';
COPY mysql_db.tbl FROM 'data.parquet';
```

You may also create a full copy of the database using the `COPY FROM DATABASE` statement:

```
COPY FROM DATABASE mysql_db TO my_duckdb_db;
```

UPDATE

```
UPDATE mysql_db.tbl
SET name = 'Woohoo'
WHERE id = 42;
```

DELETE

```
DELETE FROM mysql_db.tbl
WHERE id = 42;
```

ALTER TABLE

```
ALTER TABLE mysql_db.tbl
ADD COLUMN k INTEGER;
```

DROP TABLE

```
DROP TABLE mysql_db.tbl;
```

`CREATE VIEW`

```
CREATE VIEW mysql_db.v1 AS SELECT 42;
```

`CREATE SCHEMA` and `DROP SCHEMA`

```
CREATE SCHEMA mysql_db.s1;
CREATE TABLE mysql_db.s1.integers (i INTEGER);
INSERT INTO mysql_db.s1.integers VALUES (42);
SELECT * FROM mysql_db.s1.integers;
```

i
42

```
DROP SCHEMA mysql_db.s1;
```

Transactions

```
CREATE TABLE mysql_db.tmp (i INTEGER);
BEGIN;
INSERT INTO mysql_db.tmp VALUES (42);
SELECT * FROM mysql_db.tmp;
```

This returns:

i
42

```
ROLLBACK;
SELECT * FROM mysql_db.tmp;
```

This returns an empty table.

> The DDL statements are not transactional in MySQL.

Running SQL Queries in MySQL

The `mysql_query` Table Function

The `mysql_query` table function allows you to run arbitrary read queries within an attached database. `mysql_query` takes the name of the attached MySQL database to execute the query in, as well as the SQL query to execute. The result of the query is returned. Single-quote strings are escaped by repeating the single quote twice.

```
mysql_query(attached_database::VARCHAR, query::VARCHAR)
```

For example:

```
ATTACH 'host=localhost database=mysql' AS mysqldb (TYPE mysql);
SELECT * FROM mysql_query('mysqldb', 'SELECT * FROM cars LIMIT 3');
```

The `mysql_execute` Function

The `mysql_execute` function allows running arbitrary queries within MySQL, including statements that update the schema and content of the database.

```
ATTACH 'host=localhost database=mysql' AS mysqldb (TYPE mysql);
CALL mysql_execute('mysqldb', 'CREATE TABLE my_table (i INTEGER)');
```

Settings

Name	Description	Default
`mysql_bit1_as_boolean`	Whether or not to convert `BIT(1)` columns to `BOOLEAN`	`true`
`mysql_debug_show_queries`	DEBUG SETTING: print all queries sent to MySQL to stdout	`false`
`mysql_experimental_filter_pushdown`	Whether or not to use filter pushdown (currently experimental)	`false`
`mysql_tinyint1_as_boolean`	Whether or not to convert `TINYINT(1)` columns to `BOOLEAN`	`true`

Schema Cache

To avoid having to continuously fetch schema data from MySQL, DuckDB keeps schema information – such as the names of tables, their columns, etc. – cached. If changes are made to the schema through a different connection to the MySQL instance, such as new columns being added to a table, the cached schema information might be outdated. In this case, the function `mysql_clear_cache` can be executed to clear the internal caches.

```
CALL mysql_clear_cache();
```

ODBC

ODBC Extension

The `odbc_scanner` extension allows connecting to other databases (using their ODBC drivers) and run queries with the `odbc_query` or copy data from DuckDB with the `odbc_copy` functions. The extension is also available under the alias `odbc`.

Installing and Loading

> On Linux and macOS the extension requires unixODBC driver manager to be installed. See below for installation instructions.

The extension can be installed automatically, but needs to be loaded manually with:

```
LOAD odbc;
```

Usage Example

```
-- load extension
LOAD odbc;

-- open ODBC connection to a remote DB
SET VARIABLE conn = odbc_connect('Driver={Oracle driver};DBQ=//127.0.0.1:1521/XE', 'scott', 'tiger');

-- simple query
FROM odbc_query(getvariable('conn'), 'SELECT SYSTIMESTAMP FROM DUAL');

-- query with parameters
FROM odbc_query(getvariable('conn')
    'SELECT CAST(? AS NVARCHAR2(2)) || CAST(? AS VARCHAR2(5)) FROM DUAL',
    params = row('🦆', 'quack'));

-- copy data into remote DB
FROM odbc_copy(getvariable('conn'),
    source_file = 'https://blobs.duckdb.org/nl_stations.csv',
    dest_table = 'NL_TRAIN_STATIONS',
    create_table = true);

-- close connection
SELECT odbc_close(getvariable('conn'));
```

Installing the Nightly Version

ODBC extension is built using the version-independent DuckDB C API. The same binary (for the specific platform, for example: `windows_amd64`) can be installed and loaded on DuckDB version `1.2.0` or any newer version.

Binaries with the most recent changes, that are published to the DuckDB nightly repository, can be installed the following way:

```
INSTALL 'http://nightly-extensions.duckdb.org/v1.2.0/<platform>/odbc_scanner.duckdb_extension.gz';
```

> The URL with the version `1.2.0` in it should be used even if you are running later version of DuckDB.

Where the <platform>{:.language-sql .highlight} is one of:

- `linux_amd64`
- `linux_arm64`
- `linux_amd64_musl`
- `linux_arm64_musl`
- `osx_amd64`
- `osx_arm64`
- `windows_amd64`
- `windows_arm64`

To update installed extension to the latest nightly version run:

```
FORCE INSTALL 'http://nightly-extensions.duckdb.org/v1.2.0/<platform>/odbc_scanner.duckdb_extension.gz';
```

Installed version (commit ID) can be checked using the following query:

```
FROM duckdb_extensions()
WHERE extension_name = 'odbc_scanner';
```

To install a version built from a specific commit run:

```
FORCE INSTALL 'http://nightly-extensions.duckdb.org/odbc_scanner/<7_character_commit_
id>/v1.2.0/<platform>/odbc_scanner.duckdb_extension.gz';
```

Support Status of DBMS-Specific Types

Tier 1:

- Oracle: types coverage status
- SQL Server: types coverage status
- DB2: types coverage status

Tier 2:

- PostgreSQL: basic types covered
- MySQL/MariaDB: basic types covered
- Firebird: types coverage status

Tier 3:

- Snowflake: types coverage status
- ClickHouse: basic types covered
- Spark: basic types covered
- Arrow Flight SQL: basic types covered

Installing unixODBC Driver Manager on Linux or macOS

On Linux `unixODBC` can be installed using the system package manager. Depending on the Linux distribution one of the following installation commands can be used.

Debian, Ubuntu:

```
sudo apt-get install unixodbc
```

RHEL, Alma, Rocky, Amazon, Fedora:

```
sudo dnf install unixODBC
```

Alpine:

```
sudo apk add unixodbc
```

On macOS unixODBC can be installed using the Homebrew package manager:

```
brew install unixodbc
```

To use legacy x86_64 ODBC drivers under the Rosetta translator, the unixODBC must be installed using the x86_64 version of Homebrew:

```
arch -x86_64 /bin/bash -c "$(curl -fsSL
https://raw.githubusercontent.com/Homebrew/install/HEAD/install.sh)"
/usr/local/bin/brew install unixodbc
```

Connection String Examples

ODBC connection can be established using a data source name in a form `DSN=data_source1_name` or without a configured data source in a form `Driver={Driver name};parameter1=values1;...`.

`odbc_list_drivers` and `odbc_list_data_sources` functions can be used to find out available drivers and data sources.

Example of connection strings without a configured data source:

Oracle:

```
Driver={Oracle in instantclient_23_0};DBQ=//127.0.0.1:1521/XE;UID=scott;PWD=tiger;
```

SQL Server:

```
Driver={ODBC Driver 18 for SQL Server};Server=tcp:127.0.0.1,1433;UID=sa;PWD=pwd;TrustServerCertificate=Ye
```

DB2:

```
Driver={IBM DB2 ODBC DRIVER};HostName=127.0.0.1;Port=50000;Database=testdb;UID=db2inst1;PWD=pwd;
```

PostgreSQL:

```
Driver={PostgreSQL
Unicode};Server=127.0.0.1;Port=5432;Username=postgres;Password=postgres;Database=test_db;
```

MySQL/MariaDB:

```
Driver={MariaDB ODBC 3.1 Driver};SERVER=127.0.0.1;PORT=3306;USER=root;PASSWORD=root;DATABASE=test_db;
```

Firebird:

```
Driver={Firebird ODBC
Driver};Database=127.0.0.1/3050:C:/path/to/test.fdb;UID=SYSDBA;PWD=pwd;CHARSET=UTF8;
```

Snowflake:

```
Driver={SnowflakeDSIIDriver};Server=foobar-ab12345.snowflakecomputing.com;Database=SNOWFLAKE_SAMPLE_
DATA;UID=username;PWD=pwd;
```

ClickHouse:

```
Driver={ClickHouse ODBC Driver (Unicode)};Server=127.0.0.1;Port=8123;
```

Spark:

```
Driver={Simba Spark ODBC Driver};Host=127.0.0.1;Port=10000;
```

Arrow Flight SQL (Dremio ODBC + GizmoSQL):

```
Driver={Dremio Flight SQL ODBC Driver};Host=127.0.0.1;Port=31337;UID=gizmosql_username;PWD=gizmosql_
password;useEncryption=true;
```

Query Parameters

When a DuckDB query is run using prepared statement, it is possible to pass input parameters from the client code. The extension allows to forward such input parameters over ODBC API to the queries to remote databases.

Two methods of passing query parameters are supported, using either `params` or `params_handle` named argument to `odbc_query` function.

`params` argument takes a STRUCT value as an input. Struct field names are ignored, so the `row()` function can be used to create a STRUCT value inline:

```
FROM odbc_query(
    getvariable('conn'),
    '
      SELECT CAST(? AS VARCHAR2(3)) || CAST(? AS VARCHAR2(3)) FROM DUAL
    ',
    params = row(?, ?))
```

If we prepare this query with `duckdb_prepare()`, bind `foo` and `bar` VARCHAR values to it with `duckdb_bind_value()` and execute it with `duckdb_execute_prepared()` - the input parameters `foo` and `bar` will be forwarded to the ODBC query in the remote DB.

The problem with this approach, is that DuckDB is unable to resolve parameter types (specified in the outer query) before `duckdb_execute_prepared()` is called - such types may be different in subsequent invocations of `duckdb_execute_prepared()` and there is no way to specify these types explicitly.

This will result in re-preparing the inner query in remote DB every time `duckdb_execute_prepared()` is called.

To avoid this problem is it possible to use 2-step parameter binding with `params_handle` named argument to `odbc_query`:

```
-- create parameters handle
SET VARIABLE params = odbc_create_params();

-- when 'duckdb_prepare()' is called, the inner query will be prepared in the remote DB
FROM odbc_query(
    getvariable('conn'),
    '
      SELECT CAST(? AS VARCHAR2(3)) || CAST(? AS VARCHAR2(3)) FROM DUAL
    ',
    params_handle = getvariable('params'));

-- now we can repeatedly bind new parameters to the handle using 'odbc_bind_params()'
-- and call 'duckdb_execute_prepared()' to run the prepared query with
-- these new parameters in remote DB
SELECT odbc_bind_params(getvariable('conn'), getvariable('params'), row(?, ?));
```

Parameter handle is tied to the prepared statement and will be freed when the statement is destroyed.

Connections and Concurrency

DuckDB uses a multi-threaded execution engine to run parts of the query in parallel. ODBC drivers may or may not support using the same connection from different threads concurrently. To prevent possible concurrency problems the extension does not allow to use the same connection from multiple threads. For example, the following query:

```
FROM odbc_query(getvariable('conn'), 'SELECT ''foo'' col1 FROM DUAL')
UNION ALL
FROM odbc_query(getvariable('conn'), 'SELECT ''bar'' col1 FROM DUAL');
```

will fail with:

```
Invalid Input Error:
'odbc_query' error: ODBC connection not found on global init, id: 139760181976192
```

This can be avoided by using multiple ODBC connections:

```
FROM odbc_query(getvariable('conn1'), 'SELECT ''foo'' col1 FROM DUAL')
UNION ALL
FROM odbc_query(getvariable('conn2'), 'SELECT ''bar'' col1 FROM DUAL');
```

Or by disabling multi-threaded execution setting `threads` DuckDB option to `1`.

Transaction Management

According to ODBC specification, connections to remote DB are expected to have auto-commit mode enabled by default.

As a general rule, transaction commands `BEGIN TRANSACTION`/`COMMIT`/`ROLLBACK` are not supposed to be sent over ODBC as SQL commands. Doing so may or may not be supported by the particular driver. Instead ODBC provides the API to manage transactions.

This API is exposed in the following functions:

- `odbc_begin_transaction`
- `odbc_commit`
- `odbc_rollback`

When `odbc_begin_transaction` is called on the connection, the auto-commit mode on this connection is disabled and an implicit transaction is started. There is currently no support for enabling auto-commit back on such connection.

After the transaction is started, call `odbc_commit` or `odbc_rollback` to complete this transaction. After the completion is performed, new implicit transaction is started on this connection automatically.

Performance

ODBC is not a high-performance API, `odbc_query` uses multiple API calls per-row and performs `UCS-2` to `UTF-8` conversion for every `VARCHAR` value. Besides that, query processing is strictly single-threaded.

When submitting issues related only to performance please check the performance in comparable scenarios, for example with pyodbc.

ODBC Extension Functions

- `odbc_begin_transaction`
- `odbc_bind_params`
- `odbc_close`
- `odbc_commit`
- `odbc_connect`
- `odbc_copy`
- `odbc_create_params`
- `odbc_list_data_sources`
- `odbc_list_drivers`
- `odbc_query`
- `odbc_rollback`

odbc_begin_transaction

```
odbc_begin_transaction(conn_handle BIGINT) -> VARCHAR
```

Sets the `SQL_ATTR_AUTOCOMMIT` attribute to `SQL_AUTOCOMMIT_OFF` on the specified connection thus effectively starting an implicit transaction. `odbc_commit` or `odbc_rollback` must be called on such connection to complete the transaction. The completion starts another implicit transaction on this connection. See Transactions management for details.

Parameters:

- `conn_handle` (`BIGINT`): ODBC connection handle created with `odbc_connect`

Returns: Always returns `NULL` (`VARCHAR`).

Example:

```
SELECT odbc_begin_transaction(getvariable('conn'))
```

odbc_bind_params

```
odbc_bind_params(conn_handle BIGINT, params_handle BIGINT, params STRUCT) -> BIGINT
```

Binds specified parameter values to the specified parameters handle. Only necessary with 2-step parameters binding, see Query parameters for details.

Parameters:

- `conn_handle` (`BIGINT`): ODBC connection handle created with `odbc_connect`
- `params_handle` (`BIGINT`): parameters handle created with `odbc_create_params`
- `params` (`STRUCT`): parameters values

Returns: Parameters handle (`BIGINT`), the same one that was passed as a second argument.

Example:

```
SELECT odbc_bind_params(getvariable('conn'), getvariable('params1'), row(42, 'foo'))
```

odbc_close

```
odbc_close(conn_handle BIGINT) -> VARCHAR
```

Closes specified ODBC connection to a remote DB. Does not throw errors if the connection is already closed.

Parameters:

- `conn_handle` (`BIGINT`): ODBC connection handle created with `odbc_connect`

Returns: Always returns `NULL` (`VARCHAR`).

Example:

```
SELECT odbc_close(getvariable('conn'))
```

odbc_commit

```
odbc_commit(conn_handle BIGINT) -> VARCHAR
```

Calls `SQLEndTran` with `SQL_COMMIT` argument on the specified connection, completing the current transaction. `odbc_begin_transaction` must be called on this connection before this call for the completion to be effective. See Transactions management for details.

Parameters:

- `conn_handle` (`BIGINT`): ODBC connection handle created with `odbc_connect`

Returns: Always returns `NULL` (`VARCHAR`).

Example:

```
SELECT odbc_commit(getvariable('conn'))
```

odbc_connect

```
odbc_connect(conn_string VARCHAR) -> BIGINT
```

```
odbc_connect(conn_string VARCHAR, username VARCHAR, password VARCHAR) -> BIGINT
```

Opens an ODBC connection to a remote DB.

If `username` and `password` (positional) parameters are specified, they are appended to the connection string as `UID` and `PWD`.

Parameters:

- `conn_string` (`VARCHAR`): ODBC connection string, passed to the Driver Manager.

Returns: Connection handle that can be placed into a `VARIABLE`. Connection is not closed automatically, must be closed with `odbc_close`.

Example:

```
SET VARIABLE conn = odbc_connect('Driver={Oracle Driver};DBQ=//127.0.0.1:1521/XE;UID=scott;PWD=tiger')
```

```
SET VARIABLE conn = odbc_connect('Driver={Oracle Driver};DBQ=//127.0.0.1:1521/XE', 'scott', 'tiger')
```

odbc_copy

```
odbc_copy(conn_handle BIGINT, [, <optional named parameters>]) -> TABLE
```

```
odbc_copy(conn_string VARCHAR, [, <optional named parameters>]) -> TABLE
```

Copies rows from a DuckDB accessible file or table into the remote DB.

> **Warning.** Using `odbc_copy` from Python Relational API.
>
> `odbc_copy` is a table function that returns one row for each 2048 copied rows. When it is used from Python with `duckdb.sql()` the Lazy Evaluation is taking place. Thus no rows will be copied until a method that triggers execution is called on the resulting relation and all result rows are consumed.

Parameters:

- `conn_handle_or_string` (`BIGINT` or `VARCHAR`), one of:
  - ODBC connection handle created with `odbc_connect`
  - ODBC connection string, intended for one-off queries, in this case new ODBC connection will be opened and will be closed automatically after the query is complete

Optional named parameters (source):

> Source query is executed using a separate DB instance from the instance on which `odbc_copy` is being called. Thus `source_query` cannot refer to pre-existing in-memory tables and cannot open currently opened DuckDB files. As a workaround, for complex source queries it is suggested to export the query result into a local Parquet file first and then run `odbc_copy` on that file.

- `source_conn_string` (VARCHAR, default: `:memory:`): DuckDB connection string to the source DB, example: `ducklake:postgres:postgresql://username:pwd@127.0.0.1:5432/lake1`
- `source_file` (VARCHAR): path to a Parquet, CSV or JSON file (remote or local) to be read with DuckDB, example: `https://blobs.duckdb.org/nl_stations.csv`, equivalent to `source_query='SELECT * FROM '<source_file>'`
- `source_query` (VARCHAR): DuckDB SQL query to read the data, example: `FROM nl_train_stations`
- `source_queries` (`LIST(VARCHAR)`): multiple DuckDB SQL queries executed one by one, last query must return the result set to copy, results of previous queries are discarded, results of all queries are materialized in memory, example:

```
source_queries=[
  'CREATE SECRET s (TYPE s3 [...])',
  'FROM nl_train_stations'
],
```

- `source_limit` (UBIGINT, default: `0`): the number of records to read from source query/file at once, when this option is specified - the source query is run multiple times appending `LIMIT <limit> OFFSET <offset>` to it, must be more or equal to `2048`, `2048` must be dividable by it without a remainder

Optional named parameters (destination):

- `dest_table` (VARCHAR): destination table name in remote DB, will be used in `INSERT` and `CREATE TABLE` queries, cannot be specified if `dest_query` is specified; different DBs have different rules regarding case sensitivity and the default case, thus the name of the destination table may need to be specified in upper-case: `TAB1` or in quoted form: `"tab1"` (or with a schema name: `"schema1"."tab1"`)
- `dest_query` (VARCHAR): query to be executed in remote DB for each source batch, must have the number of ODBC parameter placeholders `?` equal to the `source_columns_count * batch_size`, cannot be specified if `dest_table` is specified, example: `CALL import_city(?,?,?,?)`
- `dest_query_single` (VARCHAR): only used when the `batch_size>0` and the number of rows read in the last source batch are less than the `batch_size`, in this case used instead of `dest_query`, must have the number of ODBC parameter placeholders `?` equal to the `source_columns_count`

Optional named parameters (create table):

- `create_table` (BOOLEAN, default: `FALSE`): whether to create a table in the destination remote DB using the column names and column types from the source query, effectively implements CTAS (create table as select)
- `column_types` (`MAP(VARCHAR, VARCHAR)`): when `create_table=TRUE` is specified, allows to provide/override the type mapping between source DuckDB types and destination RDBMS types, example:

```
create_table=TRUE,
column_types=MAP {
    'DUCKDB_TYPE_VARCHAR': 'VARCHAR2(10)',
    'DUCKDB_TYPE_DECIMAL': 'NUMBER({typmod1},{typmod2})'}
```

- `column_quotes` (VARCHAR, default: `"`): quotation character (or string) to be used to quote column names in the generated `CREATE TABLE` and `INSERT` queries
- `commit_after_create_table` (BOOLEAN, default: `FALSE`): whether to issue a `COMMIT` after executing `CREATE TABLE`, enabled automatically for Firebird

Optional named parameters (query parameters handling):

- `decimal_params_as_chars` (BOOLEAN, default: `false`): pass `DECIMAL` parameters as `VARCHAR`s
- `integral_params_as_decimals` (BOOLEAN, default: `false`): pass (unsigned) `TINYINT`, `SMALLINT`, `INTEGER` and `BIGINT` parameters as `SQL_C_NUMERIC`.

Optional named parameters (other):

- `batch_size` (`UINTEGER`, default: `16`): number of records to be inserted (or executed in case of `dest_query`) in a single `SQLExecute` ODBC call to remote DB, allowed values: `1`, `2`, `4`, `8`, `16`, `32`, `64`, `128`, `256`, `512`, `1024`, `2048`
- `use_insert_all` (`BOOLEAN`, default: `FALSE`): generate `INSERT ALL` batch insert query instead of batch insert with `INSERT ... VALUES (...), (...), ... (...)`, enabled automatically for Oracle
- `use_insert_union` (`BOOLEAN`, default: `FALSE`): generate `INSERT ... SELECT FROM ... UNION ALL ...` batch insert query instead of batch insert with `INSERT ... VALUES (...), (...), ... (...)`, enabled automatically for Firebird
- `dummy_table_name` (`VARCHAR`): name of the dummy table use for `INSERT ALL` and `INSERT UNION` queries, `dual` for Oracle
- `copy_in_transaction` (`BOOLEAN`, default: `TRUE`): begin a transaction in remote DB for this copy call, commit transaction when all rows are processed, roll it back on error
- `max_records_in_transaction` (`UBIGINT`, default: `0`): when specified causes the remote transaction to be committed every time after the specified number of rows is processed
- `close_connection` (`BOOLEAN`, default: `false`): closes the passed connection after the function call is completed, intended to be used with one-shot invocations of the `odbc_copy`

Returns: A table with the following columns:

- `completed` (`BOOLEAN`): a flag whether this output row is the last row in result set
- `rows_processed` (`UBIGINT`): a number of rows read from the source
- `elapsed_seconds` (`FLOAT`): a number of seconds passed after the copy process has started
- `rows_per_second` (`FLOAT`): a number of rows processed in one second
- `table_ddl` (`VARCHAR`): generated `CREATE TABLE` query that was executed in remote DB before starting the copy process

One resulting row is emitted for every `2048` rows read from source. Only the last row has the `completed=TRUE` and non null `table_ddl` (only when `create_table=TRUE` is specified) values.

Examples:

```
FROM odbc_copy(getvariable('conn'),
  source_file='https://blobs.duckdb.org/nl_stations.csv',
  dest_table='NL_TRAIN_STATIONS',
  create_table=TRUE)
```

```
FROM odbc_copy(getvariable('conn'),
  source_conn_string='ducklake:postgres:postgresql://username:pwd@127.0.0.1:5432/lake1',
  source_queries=[
    'CREATE SECRET s (TYPE s3 [...])',
    'FROM nl_train_stations'
  ],
  dest_table='NL_TRAIN_STATIONS',
  create_table=TRUE,
  batch_size=32,
  max_records_in_transaction=42);
```

odbc_create_params

```
odbc_create_params() -> BIGINT
```

Creates a parameters handle. Only necessary with 2-step parameters binding, see Query parameters for details.

Parameters: None.

Returns: Parameters handle (`BIGINT`). When the handle is passed to `odbc_query` it gets tied to the underlying prepared statement and is closed automatically when the statement is closed.

Example:

```
SET VARIABLE params1 = odbc_create_params()
```

odbc_list_data_sources

```
odbc_list_data_sources() -> TABLE(name VARCHAR, description VARCHAR, type VARCHAR)
```

Returns the list of ODBC data sources registered in the OS. Uses driver manager call `SQLDataSources`.

Parameters: None.

Returns: A table with the following columns:

- `name` (VARCHAR): data source name
- `description` (VARCHAR): data source description
- `type` (VARCHAR): data source type, `USER` or `SYSTEM`

Example:

```
FROM odbc_list_data_sources()
```

odbc_list_drivers

```
odbc_list_drivers() -> TABLE(description VARCHAR, attributes MAP(VARCHAR, VARCHAR))
```

Returns the list of ODBC drivers registered in the OS. Uses driver manager call `SQLDrivers`.

Parameters: None.

Returns: A table with the following columns:

- `description` (VARCHAR): driver description
- `attributes` (`MAP(VARCHAR, VARCHAR)`): driver attributes as a `name->value` map

Example:

```
FROM odbc_list_drivers()
```

odbc_query

```
odbc_query(conn_handle BIGINT, query VARCHAR[, <optional named parameters>]) -> TABLE
```

```
odbc_query(conn_string VARCHAR, query VARCHAR[, <optional named parameters>]) -> TABLE
```

Runs specified query in a remote DB and returns the query results table.

Parameters:

- `conn_handle_or_string` (`BIGINT` or `VARCHAR`), one of:
  - ODBC connection handle created with `odbc_connect`
  - ODBC connection string, intended for one-off queries, in this case new ODBC connection will be opened and will be closed automatically after the query is complete
- `query` (`VARCHAR`): SQL query, passed to the remote DBMS

Optional named parameters that can be used to pass query parameters:

- `params` (`STRUCT`): query parameters to pass to remote DBMS
- `params_handle` (`BIGINT`): parameters handle created with `odbc_create_params`. Only used with 2-step parameters binding, see Query parameters for details.

Optional named parameters that can change types mapping:

The extension supports a number of options that can be used to change how the query parameters are passed and how the resulting data is handled. For known DBs these options are set automatically. They also can be passed as named parameters to `odbc_query` function to override the autoconfiguration:

- `decimal_columns_as_chars` (`BOOLEAN`, default: `false`): read `DECIMAL` values as `VARCHAR`s that are parsed back into `DECIMAL`s before returning them to client
- `decimal_columns_precision_through_ard` (`BOOLEAN`, default: `false`): when reading a `DECIMAL` specify its `precision` and `scale` through "Application Row Descriptor"
- `decimal_columns_as_ard_type` (`BOOLEAN`, default: `false`): when reading a `DECIMAL` use `SQL_ARD_TYPE` instead of `SQL_C_NUMERIC`
- `decimal_params_as_chars` (`BOOLEAN`, default: `false`): pass `DECIMAL` parameters as `VARCHAR`s
- `integral_params_as_decimals` (`BOOLEAN`, default: `false`): pass (unsigned) `TINYINT`, `SMALLINT`, `INTEGER` and `BIGINT` parameters as `SQL_C_NUMERIC`.
- `reset_stmt_before_execute` (`BOOLEAN`, default: `false`): reset the prepared statement (using `SQLFreeStmt(h, SQL_CLOSE)`) before executing it
- `time_params_as_ss_time2` (`BOOLEAN`, default: `false`): pass `TIME` parameters as SQL Server's `TIME2` values
- `timestamp_columns_as_timestamp_ns` (`BOOLEAN`, default: `false`): read `TIMESTAMP`-like (`TIMESTAMP WITH LOCAL TIME ZONE`, `DATETIME2`, `TIMESTAMP_NTZ` etc) columns with nanosecond precision (with nine fractional digits)
- `timestamp_columns_with_typename_date_as_date` (`BOOLEAN`, default: `false`): read `TIMESTAMP` columns that have a type name `DATE` as DuckDB `DATE`s
- `timestamp_max_fraction_precision` (`UTINYINT`, default: 9): maximum number of fractional digits to use when reading a `TIMESTAMP` column with nanosecond precision
- `timestamp_params_as_sf_timestamp_ntz` (`BOOLEAN`, default: `false`): pass `TIMESTAMP` parameters as Snowflake's `TIMESTAMP_NTZ`
- `timestamptz_params_as_ss_timestampoffset` (`BOOLEAN`, default: `false`): pass `TIMESTAMP_TZ` parameters as SQL Server's `DATETIMEOFFSET`
- `var_len_data_single_part` (`BOOLEAN`, default: `false`): read long `VARCHAR` or `VARBINARY` values as a single read (used when a driver does not support Retrieving Variable-Length Data in Parts)
- `var_len_params_long_threshold_bytes` (`UINTEGER`, default: `4000`): a length threshold after that `SQL_WVARCHAR` parameters are passed as `SQL_WLONGVARCHAR`
- `enable_columns_binding` (`BOOLEAN`, default: `false`): whether to allow using `SQLBindCol` instead of `SQLGetData` for fixed-size columns

Other optional named parameters:

- `ignore_exec_failure` (`BOOLEAN`, default: `false`): when a query, that is run in remote DB, can be prepared successfully, but may or may not fail at execution time (for example, because of schema state like table existence), then this flag can be used to not throw an error when query execution fails. Empty result set is returned if query execution fails.
- `close_connection` (`BOOLEAN`, default: `false`): closes the passed connection after the function call is completed, intended to be used with one-shot invocations of the `odbc_query`, example:

```
FROM odbc_query(
   odbc_connect('Driver={Oracle Driver};DBQ=//127.0.0.1:1521/XE', 'scott', 'tiger'),
   'SELECT 42 FROM dual',
   close_connection=TRUE);
```

Returns: A table with the query result.

Example:

```
FROM odbc_query(getvariable('conn'),
  'SELECT CAST(? AS NVARCHAR2(2)) || CAST(? AS VARCHAR2(5)) FROM dual',
  params=row('🦆', 'quack')
)
```

odbc_rollback

```
odbc_rollback(conn_handle BIGINT) -> VARCHAR
```

Calls `SQLEndTran` with `SQL_ROLLBACK` argument on the specified connection, completing the current transaction. `odbc_begin_transaction` must be called on this connection before this call for the completion to be effective. See Transactions management for details.

Parameters:

- `conn_handle` (`BIGINT`): ODBC connection handle created with `odbc_connect`

Returns: Always returns `NULL` (`VARCHAR`).

Example:

```
SELECT odbc_rollback(getvariable('conn'))
```

Quack Extension

The quack extension adds support for the Quack remote protocol.

Usage

Quack is currently in a beta state. Quack will be transparently autoinstalled and autoloaded on first use.

If you would like to install Quack explicitly, run:

```
INSTALL quack;
```

If you would like to load Quack explicitly, run:

```
LOAD quack;
```

Limitations

> **Warning.** As of DuckDB v1.5.3, quack is in an experimental state. The protocol, the function names, and implementation details are all subject to change. Quack is expected to reach stable status in DuckDB v2.0.0, scheduled for September 2026.

PostgreSQL

PostgreSQL Extension

The `postgres` extension allows DuckDB to directly read and write data from a running PostgreSQL database instance. The data can be queried directly from the underlying PostgreSQL database. Data can be loaded from PostgreSQL tables into DuckDB tables, or vice versa. See the official announcement for implementation details and background.

Installing and Loading

The `postgres` extension will be transparently autoloaded on first use from the official extension repository. If you would like to install and load it manually, run:

```
INSTALL postgres;
LOAD postgres;
```

Connecting

To make a PostgreSQL database accessible to DuckDB, use the `ATTACH` command with the `postgres` or `postgres_scanner` type.

To connect to the `public` schema of the PostgreSQL instance running on localhost in read-write mode, run:

```
ATTACH '' AS postgres_db (TYPE postgres);
```

To connect to the PostgreSQL instance with the given parameters in read-only mode, run:

```
ATTACH 'dbname=postgres user=postgres host=127.0.0.1' AS db (TYPE postgres, READ_ONLY);
```

By default, all schemas are attached. When working with large instances, it can be useful to only attach a specific schema. This can be accomplished using the SCHEMA command.

```
ATTACH 'dbname=postgres user=postgres host=127.0.0.1' AS db (TYPE postgres, SCHEMA 'public');
```

Configuration

The ATTACH command takes as input either a `libpq` connection string or a PostgreSQL URI.

Below are some example connection strings and commonly used parameters. A full list of available parameters can be found in the PostgreSQL documentation.

```
dbname=postgresscanner
host=localhost port=5432 dbname=mydb connect_timeout=10
```

Name	Description	Default
`dbname`	Database name	[user]
`host`	Name of host to connect to	`localhost`
`hostaddr`	Host IP address	`localhost`

Name	Description	Default
`passfile`	Name of file passwords are stored in	`~/.pgpass`
`password`	PostgreSQL password	(empty)
`port`	Port number	`5432`
`user`	PostgreSQL user name	*current user*

An example URI is `postgresql://username@hostname/dbname`.

Configuring via Secrets

PostgreSQL connection information can also be specified with secrets, see details on the corresponding page.

Configuring via Environment Variables

PostgreSQL connection information can also be specified with environment variables. This can be useful in a production environment where the connection information is managed externally and passed in to the environment.

```
export PGPASSWORD="secret"
export PGHOST=localhost
export PGUSER=owner
export PGDATABASE=mydatabase
```

Then, to connect, start the `duckdb` process and run:

```
ATTACH '' AS p (TYPE postgres);
```

Usage

The tables in the PostgreSQL database can be read as if they were normal DuckDB tables, but the underlying data is read directly from PostgreSQL at query time.

```
SHOW ALL TABLES;
```

name
uuids

```
SELECT * FROM uuids;
```

u
6d3d2541-710b-4bde-b3af-4711738636bf
NULL
00000000-0000-0000-0000-000000000001
ffffffff-ffff-ffff-ffff-ffffffffffff

It might be desirable to create a copy of the PostgreSQL databases in DuckDB to prevent the system from re-reading the tables from PostgreSQL continuously, particularly for large tables.

Data can be copied over from PostgreSQL to DuckDB using standard SQL, for example:

```
CREATE TABLE duckdb_table AS FROM postgres_db.postgres_tbl;
```

Writing Data to PostgreSQL

In addition to reading data from PostgreSQL, the extension allows you to create tables, ingest data into PostgreSQL and make other modifications to a PostgreSQL database using standard SQL queries.

This allows you to use DuckDB to, for example, export data that is stored in a PostgreSQL database to Parquet, or read data from a Parquet file into PostgreSQL.

Below is a brief example of how to create a new table in PostgreSQL and load data into it.

```
ATTACH 'dbname=postgresscanner' AS postgres_db (TYPE postgres);
CREATE TABLE postgres_db.tbl (id INTEGER, name VARCHAR);
INSERT INTO postgres_db.tbl VALUES (42, 'DuckDB');
```

Many operations on PostgreSQL tables are supported. All these operations directly modify the PostgreSQL database, and the result of subsequent operations can then be read using PostgreSQL. Note that if modifications are not desired, ATTACH can be run with the READ_ONLY property which prevents making modifications to the underlying database. For example:

```
ATTACH 'dbname=postgresscanner' AS postgres_db (TYPE postgres, READ_ONLY);
```

Below is a list of supported operations.

CREATE TABLE

```
CREATE TABLE postgres_db.tbl (id INTEGER, name VARCHAR);
```

INSERT INTO

```
INSERT INTO postgres_db.tbl VALUES (42, 'DuckDB');
```

SELECT

```
SELECT * FROM postgres_db.tbl;
```

id	name
42	DuckDB

COPY

You can copy tables back and forth between PostgreSQL and DuckDB:

```
COPY postgres_db.tbl TO 'data.parquet';
COPY postgres_db.tbl FROM 'data.parquet';
```

These copies use PostgreSQL binary wire encoding. DuckDB can also write data using this encoding to a file which you can then load into PostgreSQL using a client of your choosing if you would like to do your own connection management:

```
COPY 'data.parquet' TO 'pg.bin' WITH (FORMAT postgres_binary);
```

The file produced will be the equivalent of copying the file to PostgreSQL using DuckDB and then dumping it from PostgreSQL using `psql` or another client:

DuckDB:

```
COPY postgres_db.tbl FROM 'data.parquet';
```

PostgreSQL:

```
\copy tbl TO 'data.bin' WITH (FORMAT BINARY);
```

You may also create a full copy of the database using the COPY FROM DATABASE statement:

```
COPY FROM DATABASE postgres_db TO my_duckdb_db;
```

UPDATE

```
UPDATE postgres_db.tbl
SET name = 'Woohoo'
WHERE id = 42;
```

DELETE

```
DELETE FROM postgres_db.tbl
WHERE id = 42;
```

ALTER TABLE

```
ALTER TABLE postgres_db.tbl
ADD COLUMN k INTEGER;
```

DROP TABLE

```
DROP TABLE postgres_db.tbl;
```

CREATE VIEW

```
CREATE VIEW postgres_db.v1 AS SELECT 42;
```

CREATE SCHEMA / DROP SCHEMA

```
CREATE SCHEMA postgres_db.s1;
CREATE TABLE postgres_db.s1.integers (i INTEGER);
INSERT INTO postgres_db.s1.integers VALUES (42);
SELECT * FROM postgres_db.s1.integers;
```

i
42

```
DROP SCHEMA postgres_db.s1;
```

DETACH

```
DETACH postgres_db;
```

Transactions

```
CREATE TABLE postgres_db.tmp (i INTEGER);
BEGIN;
INSERT INTO postgres_db.tmp VALUES (42);
SELECT * FROM postgres_db.tmp;
```

This returns:

i
42

```
ROLLBACK;
SELECT * FROM postgres_db.tmp;
```

This returns an empty table.

Running SQL Queries in PostgreSQL

The `postgres_query` Table Function

The `postgres_query` table function allows you to run arbitrary read queries within an attached database. `postgres_query` takes the name of the attached PostgreSQL database to execute the query in, as well as the SQL query to execute. The result of the query is returned. Single-quote strings are escaped by repeating the single quote twice.

```
postgres_query(attached_database::VARCHAR, query::VARCHAR)
```

For example:

```
ATTACH 'dbname=postgresscanner' AS postgres_db (TYPE postgres);
SELECT * FROM postgres_query('postgres_db', 'SELECT * FROM cars LIMIT 3');
```

brand	model	color
Ferrari	Testarossa	red
Aston Martin	DB2	blue
Bentley	Mulsanne	gray

The `postgres_execute` Function

The `postgres_execute` function allows running arbitrary queries within PostgreSQL, including statements that update the schema and content of the database.

```
ATTACH 'dbname=postgresscanner' AS postgres_db (TYPE postgres);
CALL postgres_execute('postgres_db', 'CREATE TABLE my_table (i INTEGER)');
```

Settings

The extension exposes the following configuration parameters.

Name	Description	Default
pg_array_as_varchar	Read PostgreSQL arrays as varchar - enables reading mixed dimensional arrays	false
pg_connection_cache	Whether or not to use the connection cache	true
pg_connection_limit	The maximum amount of concurrent PostgreSQL connections	64
pg_debug_show_queries	DEBUG SETTING: print all queries sent to PostgreSQL to stdout	false
pg_experimental_filter_pushdown	Whether or not to use filter pushdown (currently experimental)	true
pg_pages_per_task	The amount of pages per task	1000
pg_use_binary_copy	Whether or not to use BINARY copy to read data	true
pg_null_byte_replacement	When writing NULL bytes to Postgres, replace them with the given character	NULL
pg_use_ctid_scan	Whether or not to parallelize scanning using table ctids	true

Schema Cache

To avoid having to continuously fetch schema data from PostgreSQL, DuckDB keeps schema information – such as the names of tables, their columns, etc. – cached. If changes are made to the schema through a different connection to the PostgreSQL instance, such as new columns being added to a table, the cached schema information might be outdated. In this case, the function `pg_clear_cache` can be executed to clear the internal caches.

```
CALL pg_clear_cache();
```

> **Deprecated.** The old `postgres_attach` function is deprecated. It is recommended to switch over to the new ATTACH syntax.

Working with hstore Columns

DuckDB will return data from hstore columns as VARCHAR of their text representation, like `key=>value, foo=>bar`. You can use the postgres_hstore_get function to read the value for a given key, or postgres_hstore_to_json to convert the whole set of key/value pairs to JSON for further processing.

```
SELECT postgres_hstore_get('a=>b, c=>d', 'a');
-- b

SELECT postgres_hstore_get('a=>b, c=>d', 'missingkey');
-- NULL

SELECT postgres_hstore_to_json('a=>b, c=>d, e => null');
-- {"a": "b", "c": "d", e: null}
```

PostgreSQL Extension and the Secret Manager

User credentials and other PostgreSQL database connection details can be stored using the DuckDB Secrets Manager. The following syntax can be used to create a secret:

```
CREATE SECRET (
    TYPE postgres,
    HOST '127.0.0.1',
    PORT 5432,
    DATABASE postgres,
    USER 'postgres',
```

```
    PASSWORD ''
);
```

The information from the secret will be used when ATTACH is called. We can leave the PostgreSQL connection string empty to use all of the information stored in the secret.

```
ATTACH '' AS postgres_db (TYPE postgres);
```

We can use the PostgreSQL connection string to override individual options. For example, to connect to a different database while still using the same credentials, we can override only the database name in the following manner.

```
ATTACH 'dbname=my_other_db' AS postgres_db (TYPE postgres);
```

By default, created secrets are temporary. Secrets can be persisted using the CREATE PERSISTENT SECRET command. Persistent secrets can be used across sessions.

Managing Multiple Secrets

Named secrets can be used to manage connections to multiple PostgreSQL database instances. Secrets can be given a name upon creation.

```
CREATE SECRET postgres_secret_one (
    TYPE postgres,
    HOST '127.0.0.1',
    PORT 5432,
    DATABASE postgres,
    USER 'postgres',
    PASSWORD ''
);
```

The secret can then be explicitly referenced using the SECRET parameter in the ATTACH.

```
ATTACH '' AS postgres_db_one (TYPE postgres, SECRET postgres_secret_one);
```

> **Warning.** Avoid including credentials directly in the connection string. If a connection error occurs, the full connection string (including your credentials) may be printed to the terminal output. For better security, store credentials using DuckDB-managed secrets.

Secret Configuration Options

Secrets of type `postgres` support a number of configuration options. The following options are named after the corresponding connection options of libpq:

- HOST
- HOSTADDR
- PORT
- DBNAME
- USER
- PASSWORD
- PASSFILE
- REQUIRE_AUTH
- CHANNEL_BINDING
- CONNECT_TIMEOUT
- CLIENT_ENCODING
- OPTIONS
- APPLICATION_NAME
- FALLBACK_APPLICATION_NAME
- KEEPALIVES

- KEEPALIVES_IDLE
- KEEPALIVES_INTERVAL
- KEEPALIVES_COUNT
- TCP_USER_TIMEOUT
- REPLICATION
- GSSENCMODE
- SSLMODE
- REQUIRESSL
- SSLNEGOTIATION
- SSLCOMPRESSION
- SSLCERT
- SSLKEY
- SSLKEYLOGFILE
- SSLPASSWORD
- SSLCERTMODE
- SSLROOTCERT
- SSLCRL
- SSLCRLDIR
- SSLSNI
- REQUIREPEER
- SSL_MIN_PROTOCOL_VERSION
- SSL_MAX_PROTOCOL_VERSION
- MIN_PROTOCOL_VERSION
- MAX_PROTOCOL_VERSION
- KRBSRVNAME
- GSSLIB
- GSSDELEGATION
- SCRAM_CLIENT_KEY
- SCRAM_SERVER_KEY
- SERVICE
- TARGET_SESSION_ATTRS
- LOAD_BALANCE_HOSTS
- OAUTH_ISSUER
- OAUTH_CLIENT_ID
- OAUTH_CLIENT_SECRET
- OAUTH_SCOPE

The following options are renamed to the corresponding keys:

- DATABASE – alias to DBNAME
- HOSTNAME – alias to HOST
- USERNAME – alias to USER

Instead of separate connection options, the full connection URI can be specified instead:

- URI – connection URI

Additional option is used for AWS RDS IAM authentication, see details in the next section below:

- AWS_RDS_SECRET – the name of the secret of type `rds`

AWS RDS IAM Authentication

Managed PostgreSQL databases running on RDS/Aurora services allow to use IAM authentication. In that case the authentication token is generated using AWS SDK and must be refreshed every 15 minutes.

The `postgres` extension supports IAM authentication, when the password is not specified in the secret, but instead one of the configured AWS Credential Providers is used to generate the password, that is refreshed by the `postgres` extension automatically.

Connecting with IAM Authentication from Command Line

> This section illustrates the process with `psql` utility, not with DuckDB. This method can be used to check the configuration before setting up DuckDB secrets.

When IAM authentication is performed using `psql` command line tool, the following are the AWS-recommended connection steps:

- Generate authentication token using `aws` CLI.
- Pass this token as a `password` connection option:

```
export RDSHOST="database-1-instance-1.xxx.eu-west-1.rds.amazonaws.com"
psql "host=$RDSHOST port=5432 dbname=postgres user=postgres sslmode=require password=$(aws rds
generate-db-auth-token --hostname $RDSHOST --port 5432 --username postgres --region eu-west-1)"
```

Configuring Secrets for IAM Authentication

Authentication from the `postgres` extension uses the same logic as with `psql`:

- The secret of type `rds` is used to generate the authentication token, it takes the same configuration parameters as the `aws rds generate-db-auth-token` command in the example above:

```
CREATE SECRET aws_rds_secret1 (
    TYPE rds,
    PROVIDER credential_chain,
    CHAIN 'env;sso;',
    REGION 'eu-west-1',
    RDS_USER 'postgres',
    RDS_HOST 'database-1-instance-1.xxxxxxxxxxxx.eu-west-1.rds.amazonaws.com',
    RDS_PORT '5432'
);
```

- The secret of type `postgres` is used to create the remaining of the connection string. It takes the same parameters as the `psql` utility in the example above (and additionally any relevant additional `libpq` configuration options) and requires to specify the name of the `rds` secret, that is used to generate and periodically refresh (automatically) the authentication token that is passed to server as a `password`:

```
CREATE SECRET pg_rds_secret1 (
    TYPE postgres,
    HOST 'database-1-instance-1.xxxxxxxxxxxx.eu-west-1.rds.amazonaws.com',
    PORT '5432',
    USER 'postgres',
    DATABASE 'postgres',
    SSLMODE require,
    AWS_RDS_SECRET aws_rds_secret1
);
```

The secret of type `rds` requires the `aws` extension to be installed and allows to configure AWS Credential Chain the same way as with the secret of type `s3`, see details in the AWS extension documentation.

Storing Secrets inside a PostgreSQL Database

DuckDB Secrets Manager supports pluggable Storage Providers. The `postgres` extension implements storing the secrets (of any type) as records in the PostgreSQL database table.

The following example initializes the secrets storage and insers the secret into the `duckdb_secrets` table:

```
ATTACH 'postgres:' AS p1 (
    SECRET pg_rds_secret1,
    SECRET_STORAGE_TABLE duckdb_secrets
);

CREATE OR REPLACE SECRET s3_secret1 IN postgres_p1 (
    TYPE s3,
    PROVIDER credential_chain,
    CHAIN 'env;sso;',
    PROFILE 'DatabaseAdministrator-<account_id>',
    REGION 'eu-west-1'
);
```

When `IN postgres_<attached_database>`{:.language-sql .highlight} clause of `CREATE SECRET` is specified, the secret is persisted to the `duckdb_secrets` table in the specified attached database.

> **Warning.** Secrets are written to the database table in unencrypted binary format. It is advised to use this provider for secrets that do not include confidential credentials (like the `s3` example above). For multi-tenant scenarios it is expected that Postgres Row-Level Security policies can be used to prevent users to see secrets of other users.

Different table name (for example, in a different schema) can be specified in the `SECRET_STORAGE_TABLE` parameter to the `ATTACH` command.

When the default `duckdb_secrets` table is used, it is not necessary to specify the `SECRET_STORAGE_TABLE` parameter. When a PostgreSQL database is attached, the table with the default name `duckdb_secrets` is probed automatically. If it exists then the Secret Storage instance is registerd for this attached database making all the stored secrets available in the current session. This allows to use such persistent secrets with "direct attach" scenarios, when only a connection string is specified to the `duckdb` command (other DuckDB clients may require slightly different syntax):

```
duckdb postgres:postgresql://username:password@127.0.0.1:5432/db1
```

This method can also be used with DuckLake (with PostgreSQL catalog), when an S3/object storage access secret is stored in the catalog database:

```
duckdb ducklake:postgres:postgresql://username:password@127.0.0.1:5432/db1
```

Secrets the are stored in the specific attached database can be listed using the following query:

```
FROM duckdb_secrets() WHERE storage = 'postgres_<attached_database>';
```

To disable the PostgreSQL Secret Storage completely pass the empty string `''` in the `SECRET_STORAGE_TABLE` parameter.

PostgreSQL Extension Connection Pool

PostgreSQL server spawns a backend process for every incoming client connection. This model leads to the two following points with the `postgres` extension that can cause performance problems:

- opening a new connection is relatively expensive
- the number of the connections opened at the same time should not be too high

To deal with these points the extensions uses an in-memory connection pool. With it a limited number of connections are kept open (and idle) after use and can be reused for subsequent queries.

Parallel Scans

Due to DuckDB's multithreaded query processing, `postgres` extension can open multiple connections even for queries that performs a scan for a single PostgreSQL table. The number of parallel queries running for a single table scan can be as high as the number of worker threads of the current DB instance (`threads` global configuration option).

When the `threads` parameter is set too high (that may be necessary for local processing of other queries on DuckDB side) this can lead to attempts to open an excessive number of PostgreSQL connections. To prevent this, these parallel queries (for the same table scan) are additionally limited by the maximum number of allowed connection in the connection pool (no more than 32 by default).

Even when the connection pool is configured to allow opening additional connections when all connection slots are taken (`force` acquire mode), the addtional parallel queries are always use the `try` mode. If connection for them is not available (the maximum number of connection in the pool is exceeded) - then that worked thread does not participate futher in the processing of this table scan, that proceeds with the worker threads that were able to acquire a connection from the pool.

See the description of the postgres_configure_pool function for details.

Connection Proxies

Connection pool can be the most effective when DuckDB connects directly to a PostgreSQL server and a new backend process is started for every new connection. When an intermediate transparent proxy is used between DuckDB and PostgreSQL (for example, PgBouncer) then opening a new connections only causes a new networking socket to be opened, not a full backend process.

Thus in deployment environments with connection proxies it may be better to set the idle timeout to a lower value (using `pg_pool_idle_timeout_millis` configuration option or postgres_configure_pool function) or to disable the pooling completely (by setting `pg_pool_max_connections = 0`).

Reaper Thread

The `postgres` extension supports running a background thread (so called "reaper thread") that periodically scans idle connections in the pool and closes the ones of them that exceed `idle_timeout_millis` or `max_lifetime_millis` values.

Separate thread is run for each connections pool, it can be enabled/disabled using `pg_pool_enable_reaper_thread` configuraton option.

When the reaper thread is not running, `idle_timeout_millis` or `max_lifetime_millis` values of the connections still can be checked, but they are only checked when a connection is taken from the pool or returned to the pool.

Thread-local Cache

Idle connection in a pool are available for any caller thread, be it a DuckDB internal worker thread or a new client thread. In some cases it may be beneficial to ensure, that subsequent queries from the same thread are run on the same connection as the first query. To support this the `pg_pool_enable_thread_local_cache` configuration option can be used - it makes an idle connection to be returned to a thread-local (and thread-private) cache instead of the main cache shared between all threads.

> **Warning.** Thread-local connection are not checked and not cleaned up by the reaper thread. Thread-local cache should be used with caution as cached connections, while not available to other threads, are still take the place in the pool, so can cause a "pool startvation".

Configuration Options

The following global configuration options can be used to configure the connection pool. These options are only effective for the databases attached after the option is set. To change the settings of a connection pool for a database that is already attached the postgres_configure_pool function can be used instead.

- `pg_pool_acquire_mode` (VARCHAR, default: 'force'): how to acquire connections from the pool: 'force' (always connect, ignore pool limit), 'wait' (block until available), 'try' (fail immediately if unavailable)
- `pg_pool_max_connections` (`UBIGINT`, default: `4 <= cpu_count * 1.5 <= 32`): maximum number of connections that are allowed to be cached in a connection pool for each attached Postgres database. This number can be temporary exceeded when parallel scans are used.

- `pg_pool_wait_timeout_millis` (`UBIGINT`, default: `30000`): maximum number of milliseconds to wait when acquiring a connection from a pool where all available connections are already taken.
- `pg_pool_enable_thread_local_cache` (`BOOLEAN`, default: `FALSE`): whether to enable the connection caching in thread-local cache. Such connections are getting pinned to the threads and are not made available to other threads, while still taking the place in the pool.
- `pg_pool_max_lifetime_millis` (`UBIGINT`, default: `0` not enforced): maximum number of milliseconds the connection can be kept open. This number is checked when the connection is taken from the pool and returned to the pool. When the connection pool reaper thread is enabled ('pg_pool_enable_reaper_thread' option), then this number is checked in background periodically.
- `pg_pool_idle_timeout_millis` (`UBIGINT`, default: `60000`): maximum number of milliseconds the connection can be kept idle in the pool. This number is checked when the connection is taken from the pool. When the connection pool reaper thread is enabled ('pg_pool_enable_reaper_thread' option), then this number is checked in background periodically.
- `pg_pool_enable_reaper_thread` (default: `TRUE`): whether to enable the connection pool reaper thread, that periodically scans the pool to check the 'max_lifetime_millis' and 'idle_timeout_millis' and closes the connection which exceed the specified values. Either 'max_lifetime_millis' or 'idle_timeout_millis' must be set to a non-zero value for this option to be effective.
- `pg_pool_health_check_query` (`VARCHAR`, default: `SELECT 1`): the query that is used to check that the connection is healthy. Setting this option to an empty string disables the health check.

PostgreSQL Extension Functions

- `pg_clear_cache`
- `postgres_attach`
- `postgres_configure_pool`
- `postgres_execute`
- `postgres_hstore_get`
- `postgres_hstore_to_json`
- `postgres_query`
- `postgres_scan`
- `postgres_scan_pushdown`
- `read_postgres_binary`

pg_clear_cache

```
pg_clear_cache() -> TABLE
```

Clears cached schema entries (like table names with column lists) for all attached PostgreSQL catalogs. Attached schema is going to be re-read on the next access.

Parameters None.

Returns A table with the following columns:

- `Success` (`BOOLEAN`): a flag whether the cache clearing was successfull

> Currently the table result is always returned with zero rows, so the flag value is not available.

Example

```
CALL pg_clear_cache()
```

postgres_attach

> **Warning.** This function is deprecated and is planned to be removed in future versions. The ATTACH statement is intended to be used instead.

```
postgres_attach(connection_string VARCHAR [, <optional named parameters>]) -> TABLE
```

postgres_configure_pool

```
FROM postgres_configure_pool([<optional named parameters>]) -> TABLE
```

When a PostgreSQL database is attached, a connection pool is created for this database. This function allows to change the configuration options of a connection pool for the specified attached database. It also allows to list the current effective configuration options and the collected runtime statistics of a connection pool.

Parameters

- `catalog_name` (VARCHAR): the name (alias) of the attached Postgres database to which pool the configuration change is applied and details are returned. When `NULL` (default) returns the current state of pools for all attached catalogs without changing their configuration. Must be specified and non-NULL when any other option is specified.
- `acquire_mode` (VARCHAR, default: 'force'): how to acquire connections from the pool: 'force' (always connect, ignore pool limit), 'wait' (block until available), 'try' (fail immediately if unavailable)
- `max_connections` (UBIGINT): maximum number of connections that are allowed to be cached in a connection pool for each attached Postgres database. This number can be temporary exceeded when parallel scans are used.
- `wait_timeout_millis` (UBIGINT): maximum number of milliseconds to wait when acquiring a connection from a pool where all available connections are already taken.
- `enable_thread_local_cache` (BOOLEAN): whether to enable the connection caching in thread-local cache. Such connections are getting pinned to the threads and are not made available to other threads, while still taking the place in the pool.
- `max_lifetime_millis` (UBIGINT): maximum number of milliseconds the connection can be kept open. This number is checked when the connection is taken from the pool and returned to the pool. When the connection pool reaper thread is enabled ('enable_reaper_thread' argument), then this number is checked in background periodically.
- `idle_timeout_millis` (UBIGINT): maximum number of milliseconds the connection can be kept idle in the pool. This number is checked when the connection is taken from the pool. When the connection pool reaper thread is enabled ('enable_reaper_thread' option), then this number is checked in background periodically.
- `enable_reaper_thread` (BOOLEAN): whether to enable the connection pool reaper thread, that periodically scans the pool to check the 'max_lifetime_millis' and 'idle_timeout_millis' and closes the connection which exceed the specified values. Either 'max_lifetime_millis' or 'idle_timeout_millis' must be set to a non-zero value for this option to be effective.
- `health_check_query` (VARCHAR): the query that is used to check that the connection is healthy. Setting this option to an empty string disables the health check.

Returns A table with the following columns:

- `catalog_name` (VARCHAR): the name (alias) of the attached Postgres database
- `acquire_mode` (VARCHAR): how to acquire connections from the pool: 'force' (always connect, ignore pool limit), 'wait' (block until available), 'try' (fail immediately if unavailable)
- `available_connections` (UBIGINT): the number of idle connection that are currently available in the pool
- `max_connections` (UBIGINT): maximum number of connections that are allowed to be cached in the pool.
- `wait_timeout_millis` (UBIGINT): maximum number of milliseconds to wait when acquiring a connection from a pool where all available connections are already taken; only applicable to the `wait` acquire-mode
- `cache_hits` (UBIGINT): number of times a cached connection was successfully returned from the pool
- `cache_misses` (UBIGINT): number of times a new connection was created by the pool
- `try_failures` (UBIGINT): number of times a connection was requested by the pool in `try` acquire-mode and no connection was available at the time - so no connection was provided by the pool; note that when the parallel scans are performed by the Postgres extension - worker threads always use the `try` acquire mode; when `SET threads = <number_higher_then_pool_size>` is used, then some of the worker threads are unable to obtain a connection - they return without doing any work and without throwing an error

- `thread_local_cache_enabled` (BOOLEAN): whether caching the connections caching in thread-local cache is enabled; thread-local connections are **NOT** cleared by the reaper thread
- `thread_local_cache_hits` (UBIGINT): the number of times connections were successfully acquired from a thread-local cache without going to the main pool
- `thread_local_cache_misses` (UBIGINT): the number of times connections were not available in a thread-local cache and were taken from the main pool instead
- `max_lifetime_millis` (UBIGINT): maximum number of milliseconds a connection can be kept open
- `idle_timeout_millis` (UBIGINT): maximum number of milliseconds a connection can be kept idle in the pool
- `reaper_thread_running` (BOOLEAN): whether the pool reaper thread is running; this thread periodically scans the pool to check the 'max_lifetime_millis' and 'idle_timeout_millis' and closes connections which exceed the specified values
- `reaper_thread_period_millis` (UBIGINT): the period of time when a reaper thread performs the checks
- `health_check_query` (VARCHAR): the query that is used to check that the connection is healthy

Examples List the current effective configuration options and the collected runtime statistics of all connections pools (for all attached databases):

```
FROM postgres_configure_pool()
```

Change one or more configuration option for the connection pool of the specified attached database:

```
FROM postgres_configure_pool(catalog_name='db1', acquire_mode='wait', max_connections=42)
```

postgres_execute

```
postgres_execute(attached_db_name VARCHAR, sql_query VARCHAR[, <optional named parameters>]) -> TABLE
```

Executes the query in the speicifed remote DB that was previosly attached with `ATTACH .. AS <attached_db_name>`. Does not return the query result.

Parameters

- `attached_db_name` (VARCHAR): the name of the attached PostgreSQL database
- `sql_query` (VARCHAR): query that is passed to PostgreSQL for execution; no transformation or analysis of this query is performed by DuckDB

Optional named parameters:

- `use_transaction` (BOOLEAN, default: TRUE): whether to start a PostgreSQL transaction if it was not started before.

Returns A table with the following columns:

- `Success` (BOOLEAN): a flag whether the cache clearing was successfull

> Currently the table result is always returned with zero rows, so the flag value is not available.

Example

```
CALL postgres_execute('db1', 'VACUUM ANALYZE', use_transaction=FALSE)
```

postgres_hstore_get

```
postgres_hstore_get(hstore_string VARCHAR, hstore_key VARCHAR) -> VARCHAR
```

Parses the external representation of and PostgreSQL hstore column and returns the value of the specified hstore key.

Parameters

- `hstore_string` (VARCHAR): PostgreSQL `hstore` value in `key => value` form.
- `hstore_kay` (VARCHAR): Key name to return the value for.

Returns The value for the specified key. `NULL` if the key not found.

Example

```
SELECT postgres_hstore_get('a=>b, c=>d', 'a')
```

postgres_hstore_to_json

```
postgres_hstore_to_json(hstore_string VARCHAR) -> JSON
```

Converts the external representation of and PostgreSQL hstore column into `JSON`.

Parameters

- `hstore_string` (VARCHAR): PostgreSQL `hstore` value in `key => value` form.

Returns JSON dictionary with the same key/value pairs as the input `hstore` string. All values are returned as strings.

Example

```
SELECT postgres_hstore_to_json('z=>1, a=>2, m=>3')
```

postgres_query

```
postgres_query(attached_db_name VARCHAR, sql_query VARCHAR[, <optional named parameters>]) -> TABLE
```

Executes the query in the speicifed remote DB that was previosly attached with `ATTACH .. AS <attached_db_name>` and return the query result as a table.

Parameters

- `attached_db_name` (VARCHAR): the name of the attached PostgreSQL database
- `sql_query` (VARCHAR): query that is passed to PostgreSQL for execution; no transformation or analysis of this query is performed by DuckDB

Optional named parameters:

- `use_transaction` (BOOLEAN, default: TRUE): whether to start a PostgreSQL transaction if it was not started before.
- `params` (STRUCT): query parameters that are passed to the PostgreSQL server; only supported when the text protocol is used

Returns A table with the query result.

Example

```
FROM postgres_query('db11', 'SELECT $1::INTEGER, $2::TEXT', params=row(42::INTEGER, 'foo'::VARCHAR))
```

postgres_scan

> **Warning.** This function is deprecated and is planned to be removed in future versions. Direct SQL queries over the attached PostgreSQL database are intended to be used instead.

```
postgres_scan(connection_string VARCHAR, schema_name VARCHAR, table_name VARCHAR) -> TABLE
```

postgres_scan_pushdown

> **Warning.** This function is deprecated and is planned to be removed in future versions. Direct SQL queries over the attached PostgreSQL database are intended to be used instead.

```
postgres_scan_pushdown(connection_string VARCHAR, schema_name VARCHAR, table_name VARCHAR) -> TABLE
```

read_postgres_binary

```
FROM read_postgres_binary(file_path VARCHAR[, <optional named parameters>]) -> TABLE
```

Reads PostgreSQL binary dump files from file system.

Parameters

- `file_path` (VARCHAR): FS path to the binary dump file in a PostgreSQL format.

Optional named parameters:

- `columns` (STRUCT): type mapping in form of the `column_name -> column_type` structure.
- `buffer_size` (UBIGINT, default: 32KB): size of the read buffer in bytes.

Returns Contents of the binary dump file as a table.

Example

```
COPY (SELECT 42::INTEGER AS a, 'foo'::VARCHAR AS b) TO 'path/to/test.bin' (FORMAT postgres_binary);

FROM read_postgres_binary('path/to/test.bin', columns={a: 'INTEGER', b: 'VARCHAR'});
```

Spatial

Spatial Extension

The `spatial` extension provides support for geospatial data processing in DuckDB. For an overview of the extension, see our blog post.

Installing and Loading

To install the `spatial` extension, run:

```
INSTALL spatial;
```

Note that the `spatial` extension is not autoloadable. Therefore, you need to load it before using it:

```
LOAD spatial;
```

Spatial Functions

Function Index

Scalar Functions

Function	Summary
`DuckDB_PROJ_Compiled_Version`	Returns a text description of the PROJ library version that this instance of DuckDB was compiled against.
`DuckDB_Proj_Version`	Returns a text description of the PROJ library version that is being used by this instance of DuckDB.
`ST_Affine`	Applies an affine transformation to a geometry.
`ST_Area`	Compute the area of a geometry.
`ST_Area_Spheroid`	Returns the area of a geometry in meters, using an ellipsoidal model of the earth
`ST_AsGeoJSON`	Returns the geometry as a GeoJSON fragment
`ST_AsHEXWKB`	Returns the geometry as a HEXWKB string
`ST_AsMVTGeom`	Transform and clip geometry to a tile boundary
`ST_AsSVG`	Convert the geometry into a SVG fragment or path
`ST_AsText`	Returns the geometry as a WKT string
`ST_AsWKB`	Returns the geometry as a WKB (Well-Known-Binary) blob
`ST_Azimuth`	Returns the azimuth (a clockwise angle measured from north) of two points in radian.
`ST_Boundary`	Returns the ”boundary” of a geometry
`ST_Buffer`	Returns a buffer around the input geometry at the target distance

Function	Summary
ST_BuildArea	Creates a polygonal geometry by attempting to ”fill in” the input geometry.
ST_Centroid	Returns the centroid of a geometry
ST_Collect	Collects a list of geometries into a collection geometry.
ST_CollectionExtract	Extracts geometries from a GeometryCollection into a typed multi geometry.
ST_ConcaveHull	Returns the 'concave' hull of the input geometry, containing all of the source input's points, and which can be used to create polygons from points. The ratio parameter dictates the level of concavity; 1.0 returns the convex hull; and 0 indicates to return the most concave hull possible. Set allowHoles to a non-zero value to allow output containing holes.
ST_Contains	Returns true if the first geometry contains the second geometry
ST_ContainsProperly	Returns true if the first geometry ”properly” contains the second geometry
ST_ConvexHull	Returns the convex hull enclosing the geometry
ST_CoverageInvalidEdges	Returns the invalid edges in a polygonal coverage, which are edges that are not shared by two polygons.
ST_CoverageSimplify	Simplify the edges in a polygonal coverage, preserving the coverage by ensuring that there are no seams between the resulting simplified polygons.
ST_CoverageUnion	Union all geometries in a polygonal coverage into a single geometry.
ST_CoveredBy	Returns true if geom1 is ”covered by” geom2
ST_Covers	Returns true if the geom1 ”covers” geom2
ST_Crosses	Returns true if geom1 ”crosses” geom2
ST_DWithin	Returns if two geometries are within a target distance of each-other
ST_DWithin_GEOS	Returns if two geometries are within a target distance of each-other
ST_DWithin_Spheroid	Returns if two POINT_2D's are within a target distance in meters, using an ellipsoidal model of the earths surface
ST_Difference	Returns the ”difference” between two geometries
ST_Dimension	Returns the ”topological dimension” of a geometry.
ST_Disjoint	Returns true if the geometries are disjoint
ST_Distance	Returns the planar distance between two geometries
ST_Distance_GEOS	Returns the planar distance between two geometries
ST_Distance_Sphere	Returns the haversine (great circle) distance between two geometries.
ST_Distance_Spheroid	Returns the distance between two geometries in meters using an ellipsoidal model of the earths surface
ST_Dump	Dumps a geometry into a list of sub-geometries and their ”path” in the original geometry.
ST_EndPoint	Returns the end point of a LINESTRING.

Function	Summary
ST_Envelope	Returns the minimum bounding rectangle of a geometry as a polygon geometry
ST_Equals	Returns true if the geometries are ”equal”
ST_Extent	Returns the minimal bounding box enclosing the input geometry
ST_Extent_Approx	Returns the approximate bounding box of a geometry, if available.
ST_ExteriorRing	Returns the exterior ring (shell) of a polygon geometry.
ST_FlipCoordinates	Returns a new geometry with the coordinates of the input geometry ”flipped” so that x = y and y = x
ST_Force2D	Forces the vertices of a geometry to have X and Y components
ST_Force3DM	Forces the vertices of a geometry to have X, Y and M components
ST_Force3DZ	Forces the vertices of a geometry to have X, Y and Z components
ST_Force4D	Forces the vertices of a geometry to have X, Y, Z and M components
ST_GeomFromGeoJSON	Deserializes a GEOMETRY from a GeoJSON fragment.
ST_GeomFromHEXEWKB	Deserialize a GEOMETRY from a HEX(E)WKB encoded string
ST_GeomFromHEXWKB	Deserialize a GEOMETRY from a HEX(E)WKB encoded string
ST_GeomFromText	Deserialize a GEOMETRY from a WKT encoded string
ST_GeomFromWKB	Deserializes a GEOMETRY from a WKB encoded blob
ST_GeometryType	Returns a 'GEOMETRY_TYPE' enum identifying the input geometry type. Possible enum return types are: POINT, LINESTRING, POLYGON, MULTIPOINT, MULTILINESTRING, MULTIPOLYGON and GEOMETRYCOLLECTION.
ST_HasM	Check if the input geometry has M values.
ST_HasZ	Check if the input geometry has Z values.
ST_Hilbert	Encodes the X and Y values as the hilbert curve index for a curve covering the given bounding box.
ST_InterpolatePoint	Computes the closest point on a LINESTRING to a given POINT and returns the interpolated M value of that point.
ST_Intersection	Returns the intersection of two geometries
ST_Intersects	Returns true if the geometries intersect
ST_Intersects_Extent	Returns true if the extent of two geometries intersects
ST_IsClosed	Check if a geometry is 'closed'
ST_IsEmpty	Returns true if the geometry is ”empty”.
ST_IsRing	Returns true if the geometry is a ring (both ST_IsClosed and ST_IsSimple).
ST_IsSimple	Returns true if the geometry is simple
ST_IsValid	Returns true if the geometry is valid
ST_Length	Returns the length of the input line geometry
ST_Length_Spheroid	Returns the length of the input geometry in meters, using an ellipsoidal model of the earth
ST_LineInterpolatePoint	Returns a point interpolated along a line at a fraction of total 2D length.

Function	Summary
ST_LineInterpolatePoints	Returns a multi-point interpolated along a line at a fraction of total 2D length.
ST_LineLocatePoint	Returns the location on a line closest to a point as a fraction of the total 2D length of the line.
ST_LineMerge	”Merges” the input line geometry, optionally taking direction into account.
ST_LineString2DFromWKB	Deserialize a LINESTRING_2D from a WKB encoded blob
ST_LineSubstring	Returns a substring of a line between two fractions of total 2D length.
ST_LocateAlong	Returns a point or multi-point, containing the point(s) at the geometry with the given measure
ST_LocateBetween	Returns a geometry or geometry collection created by filtering and interpolating vertices within a range of ”M” values
ST_M	Returns the M coordinate of a point geometry
ST_MMax	Returns the maximum M coordinate of a geometry
ST_MMin	Returns the minimum M coordinate of a geometry
ST_MakeBox2D	Create a BOX2D from two POINT geometries
ST_MakeEnvelope	Create a rectangular polygon from min/max coordinates
ST_MakeLine	Create a LINESTRING from a list of POINT geometries
ST_MakePoint	Creates a GEOMETRY point from an pair of floating point numbers.
ST_MakePolygon	Create a POLYGON from a LINESTRING shell
ST_MakeValid	Returns a valid representation of the geometry
ST_MaximumInscribedCircle	Returns the maximum inscribed circle of the input geometry, optionally with a tolerance.
ST_MinimumRotatedRectangle	Returns the minimum rotated rectangle that bounds the input geometry, finding the surrounding box that has the lowest area by using a rotated rectangle, rather than taking the lowest and highest coordinate values as per ST_Envelope().
ST_Multi	Turns a single geometry into a multi geometry.
ST_NGeometries	Returns the number of component geometries in a collection geometry.
ST_NInteriorRings	Returns the number of interior rings of a polygon
ST_NPoints	Returns the number of vertices within a geometry
ST_Node	Returns a ”noded” MultiLinestring, produced by combining a collection of input linestrings and adding additional vertices where they intersect.
ST_Normalize	Returns the ”normalized” representation of the geometry
ST_NumGeometries	Returns the number of component geometries in a collection geometry.
ST_NumInteriorRings	Returns the number of interior rings of a polygon
ST_NumPoints	Returns the number of vertices within a geometry
ST_Overlaps	Returns true if the geometries overlap
ST_Perimeter	Returns the length of the perimeter of the geometry

Function	Summary
ST_Perimeter_Spheroid	Returns the length of the perimeter in meters using an ellipsoidal model of the earths surface
ST_Point	Creates a GEOMETRY point
ST_Point2D	Creates a POINT_2D
ST_Point2DFromWKB	Deserialize a POINT_2D from a WKB encoded blob
ST_Point3D	Creates a POINT_3D
ST_Point4D	Creates a POINT_4D
ST_PointN	Returns the n'th vertex from the input geometry as a point geometry
ST_PointOnSurface	Returns a point guaranteed to lie on the surface of the geometry
ST_Points	Collects all the vertices in the geometry into a MULTIPOINT
ST_Polygon2DFromWKB	Deserialize a POLYGON_2D from a WKB encoded blob
ST_Polygonize	Returns a polygonized representation of the input geometries
ST_QuadKey	Compute the quadkey for a given lon/lat point at a given level.
ST_ReducePrecision	Returns the geometry with all vertices reduced to the given precision
ST_RemoveRepeatedPoints	Remove repeated points from a LINESTRING.
ST_Reverse	Returns the geometry with the order of its vertices reversed
ST_ShortestLine	Returns the shortest line between two geometries
ST_Simplify	Returns a simplified version of the geometry
ST_SimplifyPreserveTopology	Returns a simplified version of the geometry that preserves topology
ST_StartPoint	Returns the start point of a LINESTRING.
ST_TileEnvelope	The ST_TileEnvelope scalar function generates tile envelope rectangular polygons from specified zoom level and tile indices.
ST_Touches	Returns true if the geometries touch
ST_Transform	Transforms a geometry between two coordinate systems
ST_Union	Returns the union of two geometries
ST_VoronoiDiagram	Returns the Voronoi diagram of the supplied MultiPoint geometry
ST_Within	Returns true if the first geometry is within the second
ST_WithinProperly	Returns true if the first geometry ”properly” is contained by the second geometry
ST_X	Returns the X coordinate of a point geometry
ST_XMax	Returns the maximum X coordinate of a geometry
ST_XMin	Returns the minimum X coordinate of a geometry
ST_Y	Returns the Y coordinate of a point geometry
ST_YMax	Returns the maximum Y coordinate of a geometry
ST_YMin	Returns the minimum Y coordinate of a geometry
ST_Z	Returns the Z coordinate of a point geometry
ST_ZMFlag	Returns a flag indicating the presence of Z and M values in the input geometry.

Function	Summary
ST_ZMax	Returns the maximum Z coordinate of a geometry
ST_ZMin	Returns the minimum Z coordinate of a geometry

Aggregate Functions

Function	Summary
ST_AsMVT	Make a Mapbox Vector Tile from a set of geometries and properties
ST_CoverageInvalidEdges_Agg	Returns the invalid edges of a coverage geometry
ST_CoverageSimplify_Agg	Simplifies a set of geometries while maintaining coverage
ST_CoverageUnion_Agg	Unions a set of geometries while maintaining coverage
ST_Envelope_Agg	Alias for ST_Extent_Agg.
ST_Extent_Agg	Computes the minimal-bounding-box polygon containing the set of input geometries
ST_Intersection_Agg	Computes the intersection of a set of geometries
ST_MemUnion_Agg	Computes the union of a set of input geometries.
ST_Union_Agg	Computes the union of a set of input geometries

Macro Functions

Function	Summary
ST_Rotate	Alias of ST_RotateZ
ST_RotateX	Rotates a geometry around the X axis. This is a shorthand macro for calling ST_Affine.
ST_RotateY	Rotates a geometry around the Y axis. This is a shorthand macro for calling ST_Affine.
ST_RotateZ	Rotates a geometry around the Z axis. This is a shorthand macro for calling ST_Affine.
ST_Scale	
ST_TransScale	Translates and then scales a geometry in X and Y direction. This is a shorthand macro for calling ST_Affine.
ST_Translate	

Table Functions

Function	Summary
ST_Drivers	Returns the list of supported GDAL drivers and file formats
ST_GeneratePoints	Generates a set of random points within the specified bounding box.
ST_Read	Read and import a variety of geospatial file formats using the GDAL library.

Function	Summary
ST_ReadOSM	The ST_ReadOsm() table function enables reading compressed OpenStreetMap data directly from a .osm.pbf file.
ST_ReadSHP	Read a Shapefile without relying on the GDAL library
ST_Read_Meta	Read the metadata from a variety of geospatial file formats using the GDAL library.

Scalar Functions

DuckDB_PROJ_Compiled_Version

Signature

```
VARCHAR DuckDB_PROJ_Compiled_Version ()
```

Description Returns a text description of the PROJ library version that this instance of DuckDB was compiled against.

Example

```
SELECT duckdb_proj_compiled_version();
```

duckdb_proj_compiled_version()
varchar
Rel. 9.1.1, December 1st, 2022

DuckDB_Proj_Version

Signature

```
VARCHAR DuckDB_Proj_Version ()
```

Description Returns a text description of the PROJ library version that is being used by this instance of DuckDB.

Example

```
SELECT duckdb_proj_version();
```

duckdb_proj_version()
varchar
9.1.1

ST_Affine

Signatures

```
GEOMETRY ST_Affine (geom GEOMETRY, a DOUBLE, b DOUBLE, c DOUBLE, d DOUBLE, e DOUBLE, f DOUBLE, g DOUBLE,
h DOUBLE, i DOUBLE, xoff DOUBLE, yoff DOUBLE, zoff DOUBLE)
GEOMETRY ST_Affine (geom GEOMETRY, a DOUBLE, b DOUBLE, d DOUBLE, e DOUBLE, xoff DOUBLE, yoff DOUBLE)
```

Description Applies an affine transformation to a geometry.

For the 2D variant, the transformation matrix is defined as follows:

```
| a b xoff |
| d e yoff |
| 0 0 1    |
```

For the 3D variant, the transformation matrix is defined as follows:

```
| a b c xoff |
| d e f yoff |
| g h i zoff |
| 0 0 0 1    |
```

The transformation is applied to all vertices of the geometry.

Example

```
-- Translate a point by (2, 3)
SELECT ST_Affine(ST_Point(1, 1),
                 1, 0,   -- a, b
                 0, 1,   -- d, e
                 2, 3);  -- xoff, yoff
----
POINT (3 4)

-- Scale a geometry by factor 2 in X and Y
SELECT ST_Affine(ST_Point(1, 1),
                 2, 0, 0,   -- a, b, c
                 0, 2, 0,   -- d, e, f
                 0, 0, 1,   -- g, h, i
                 0, 0, 0);  -- xoff, yoff, zoff
----
POINT (2 2)
```

ST_Area

Signatures

```
DOUBLE ST_Area (geom GEOMETRY)
DOUBLE ST_Area (polygon POLYGON_2D)
DOUBLE ST_Area (linestring LINESTRING_2D)
DOUBLE ST_Area (point POINT_2D)
DOUBLE ST_Area (box BOX_2D)
```

Description Compute the area of a geometry.

Returns `0.0` for any geometry that is not a `POLYGON`, `MULTIPOLYGON` or `GEOMETRYCOLLECTION` containing polygon geometries.

The area is in the same units as the spatial reference system of the geometry.

The `POINT_2D` and `LINESTRING_2D` overloads of this function always return `0.0` but are included for completeness.

Example

```
select ST_Area('POLYGON((0 0, 0 1, 1 1, 1 0, 0 0))'::geometry);
-- 1.0
```

ST_Area_Spheroid

Signatures

```
DOUBLE ST_Area_Spheroid (geom GEOMETRY)
DOUBLE ST_Area_Spheroid (poly POLYGON_2D)
```

Description Returns the area of a geometry in meters, using an ellipsoidal model of the earth

The input geometry is assumed to be in the EPSG:4326 coordinate system (WGS84), with [latitude, longitude] axis order and the area is returned in square meters. This function uses the GeographicLib library, calculating the area using an ellipsoidal model of the earth. This is a highly accurate method for calculating the area of a polygon taking the curvature of the earth into account, but is also the slowest.

Returns `0.0` for any geometry that is not a `POLYGON`, `MULTIPOLYGON` or `GEOMETRYCOLLECTION` containing polygon geometries.

ST_AsGeoJSON

Signature

```
JSON ST_AsGeoJSON (geom GEOMETRY)
```

Description Returns the geometry as a GeoJSON fragment

This does not return a complete GeoJSON document, only the geometry fragment. To construct a complete GeoJSON document or feature, look into using the DuckDB JSON extension in conjunction with this function. This function supports geometries with Z values, but not M values. M values are ignored.

Example

```
select ST_AsGeoJSON('POLYGON((0 0, 0 1, 1 1, 1 0, 0 0))'::geometry);
----
{"type":"Polygon","coordinates":[[[0.0,0.0],[0.0,1.0],[1.0,1.0],[1.0,0.0],[0.0,0.0]]]}

-- Convert a geometry into a full GeoJSON feature (requires the JSON extension to be loaded)
SELECT CAST({
    type: 'Feature',
    geometry: ST_AsGeoJSON(ST_Point(1,2)),
    properties: {
        name: 'my_point'
    }
```

```
} AS JSON);
----
{"type":"Feature","geometry":{"type":"Point","coordinates":[1.0,2.0]},"properties":{"name":"my_point"}}
```

ST_AsHEXWKB

Signature

```
VARCHAR ST_AsHEXWKB (geom GEOMETRY)
```

Description Returns the geometry as a HEXWKB string

Example

```
SELECT ST_AsHexWKB('POLYGON((0 0, 0 1, 1 1, 1 0, 0 0))'::geometry);
----
01030000000100000005000000000000000000000000000000...
```

ST_AsMVTGeom

Signatures

```
GEOMETRY ST_AsMVTGeom (geom GEOMETRY, bounds BOX_2D, extent BIGINT, buffer BIGINT, clip_geom BOOLEAN)
GEOMETRY ST_AsMVTGeom (geom GEOMETRY, bounds BOX_2D, extent BIGINT, buffer BIGINT)
GEOMETRY ST_AsMVTGeom (geom GEOMETRY, bounds BOX_2D, extent BIGINT)
GEOMETRY ST_AsMVTGeom (geom GEOMETRY, bounds BOX_2D)
```

Description Transform and clip geometry to a tile boundary

See ”ST_AsMVT” for more details

ST_AsSVG

Signature

```
VARCHAR ST_AsSVG (geom GEOMETRY, relative BOOLEAN, precision INTEGER)
```

Description Convert the geometry into a SVG fragment or path

The SVG fragment is returned as a string. The fragment is a path element that can be used in an SVG document. The second boolean argument specifies whether the path should be relative or absolute. The third argument specifies the maximum number of digits to use for the coordinates.

Points are formatted as cx/cy using absolute coordinates or x/y using relative coordinates.

Example

```
SELECT ST_AsSVG('POLYGON((0 0, 0 1, 1 1, 1 0, 0 0))'::GEOMETRY, false, 15);
----
M 0 0 L 0 -1 1 -1 1 0 Z
```

ST_AsText

Signatures

```
VARCHAR ST_AsText (geom GEOMETRY)
VARCHAR ST_AsText (point POINT_2D)
VARCHAR ST_AsText (linestring LINESTRING_2D)
VARCHAR ST_AsText (polygon POLYGON_2D)
VARCHAR ST_AsText (box BOX_2D)
```

Description Returns the geometry as a WKT string

Example

```
SELECT ST_MakeEnvelope(0,0,1,1);
----
POLYGON ((0 0, 0 1, 1 1, 1 0, 0 0))
```

ST_AsWKB

Signature

```
WKB_BLOB ST_AsWKB (geom GEOMETRY)
```

Description Returns the geometry as a WKB (Well-Known-Binary) blob

Example

```
SELECT ST_AsWKB('POLYGON((0 0, 0 1, 1 1, 1 0, 0 0))'::GEOMETRY)::BLOB;
----
\x01\x03\x00\x00\x00\x01\x00\x00\x00\x05...
```

ST_Azimuth

Signatures

```
DOUBLE ST_Azimuth (origin GEOMETRY, target GEOMETRY)
DOUBLE ST_Azimuth (origin POINT_2D, target POINT_2D)
```

Description Returns the azimuth (a clockwise angle measured from north) of two points in radian.

Example

```
SELECT degrees(ST_Azimuth(ST_Point(0, 0), ST_Point(0, 1)));
----
90.0
```

ST_Boundary

Signature

```
GEOMETRY ST_Boundary (geom GEOMETRY)
```

Description Returns the ”boundary” of a geometry

ST_Buffer

Signatures

```
GEOMETRY ST_Buffer (geom GEOMETRY, distance DOUBLE)
GEOMETRY ST_Buffer (geom GEOMETRY, distance DOUBLE, num_triangles INTEGER)
GEOMETRY ST_Buffer (geom GEOMETRY, distance DOUBLE, num_triangles INTEGER, cap_style VARCHAR, join_style
VARCHAR, mitre_limit DOUBLE)
```

Description Returns a buffer around the input geometry at the target distance

`geom` is the input geometry.

`distance` is the target distance for the buffer, using the same units as the input geometry.

`num_triangles` represents how many triangles that will be produced to approximate a quarter circle. The larger the number, the smoother the resulting geometry. The default value is 8.

`cap_style` must be one of ”CAP_ROUND”, ”CAP_FLAT”, ”CAP_SQUARE”. This parameter is case-insensitive.

`join_style` must be one of ”JOIN_ROUND”, ”JOIN_MITRE”, ”JOIN_BEVEL”. This parameter is case-insensitive.

`mitre_limit` only applies when `join_style` is ”JOIN_MITRE”. It is the ratio of the distance from the corner to the mitre point to the corner radius. The default value is 1.0.

This is a planar operation and will not take into account the curvature of the earth.

ST_BuildArea

Signature

```
GEOMETRY ST_BuildArea (geom GEOMETRY)
```

Description Creates a polygonal geometry by attempting to ”fill in” the input geometry.

Unlike ST_Polygonize, this function does not fill in holes.

ST_Centroid

Signatures

```
GEOMETRY ST_Centroid (geom GEOMETRY)
POINT_2D ST_Centroid (point POINT_2D)
POINT_2D ST_Centroid (linestring LINESTRING_2D)
POINT_2D ST_Centroid (polygon POLYGON_2D)
POINT_2D ST_Centroid (box BOX_2D)
POINT_2D ST_Centroid (box BOX_2DF)
```

Description Returns the centroid of a geometry

ST_Collect

Signature

```
GEOMETRY ST_Collect (geoms GEOMETRY[])
```

Description Collects a list of geometries into a collection geometry.

- If all geometries are `POINT`'s, a `MULTIPOINT` is returned.
- If all geometries are `LINESTRING`'s, a `MULTILINESTRING` is returned.
- If all geometries are `POLYGON`'s, a `MULTIPOLYGON` is returned.
- Otherwise if the input collection contains a mix of geometry types, a `GEOMETRYCOLLECTION` is returned.

Empty and `NULL` geometries are ignored. If all geometries are empty or `NULL`, a `GEOMETRYCOLLECTION EMPTY` is returned.

Example

```
-- With all POINT's, a MULTIPOINT is returned
SELECT ST_Collect([ST_Point(1, 2), ST_Point(3, 4)]);
----
MULTIPOINT (1 2, 3 4)

-- With mixed geometry types, a GEOMETRYCOLLECTION is returned
SELECT ST_Collect([ST_Point(1, 2), ST_GeomFromText('LINESTRING(3 4, 5 6)')]);
----
GEOMETRYCOLLECTION (POINT (1 2), LINESTRING (3 4, 5 6))

-- Note that the empty geometry is ignored, so the result is a MULTIPOINT
SELECT ST_Collect([ST_Point(1, 2), NULL, ST_GeomFromText('GEOMETRYCOLLECTION EMPTY')]);
----
MULTIPOINT (1 2)

-- If all geometries are empty or NULL, a GEOMETRYCOLLECTION EMPTY is returned
SELECT ST_Collect([NULL, ST_GeomFromText('GEOMETRYCOLLECTION EMPTY')]);
----
GEOMETRYCOLLECTION EMPTY

-- Tip: You can use the `ST_Collect` function together with the `list()` aggregate function to collect
multiple rows of geometries into a single geometry collection:

CREATE TABLE points (geom GEOMETRY);
```

```
INSERT INTO points VALUES (ST_Point(1, 2)), (ST_Point(3, 4));

SELECT ST_Collect(list(geom)) FROM points;
----
MULTIPOINT (1 2, 3 4)
```

ST_CollectionExtract

Signatures

```
GEOMETRY ST_CollectionExtract (geom GEOMETRY, type INTEGER)
GEOMETRY ST_CollectionExtract (geom GEOMETRY)
```

Description Extracts geometries from a GeometryCollection into a typed multi geometry.

If the input geometry is a GeometryCollection, the function will return a multi geometry, determined by the `type` parameter.

- If `type` = 1, returns a MultiPoint containing all the Points in the collection.
- If `type` = 2, returns a MultiLineString containing all the LineStrings in the collection.
- If `type` = 3, returns a MultiPolygon containing all the Polygons in the collection.

If no `type` parameters is provided, the function will return a multi geometry matching the highest "surface dimension" of the contained geometries. E.g. if the collection contains only Points, a MultiPoint will be returned. But if the collection contains both Points and LineStrings, a MultiLineString will be returned. Similarly, if the collection contains Polygons, a MultiPolygon will be returned. Contained geometries of a lower surface dimension will be ignored.

If the input geometry contains nested GeometryCollections, their geometries will be extracted recursively and included into the final multi geometry as well.

If the input geometry is not a GeometryCollection, the function will return the input geometry as is.

Example

```
select st_collectionextract('MULTIPOINT(1 2,3 4)'::geometry, 1);
-- MULTIPOINT (1 2, 3 4)
```

ST_ConcaveHull

Signature

```
GEOMETRY ST_ConcaveHull (geom GEOMETRY, ratio DOUBLE, allowHoles BOOLEAN)
```

Description Returns the 'concave' hull of the input geometry, containing all of the source input's points, and which can be used to create polygons from points. The ratio parameter dictates the level of concavity; 1.0 returns the convex hull; and 0 indicates to return the most concave hull possible. Set allowHoles to a non-zero value to allow output containing holes.

ST_Contains

Signatures

```
BOOLEAN ST_Contains (geom1 POLYGON_2D, geom2 POINT_2D)
BOOLEAN ST_Contains (geom1 GEOMETRY, geom2 GEOMETRY)
```

Description Returns true if the first geometry contains the second geometry

In contrast to `ST_ContainsProperly`, this function will also return true if `geom2` is contained strictly on the boundary of `geom1`. A geometry always `ST_Contains` itself, but does not `ST_ContainsProperly` itself.

ST_ContainsProperly

Signature

```
BOOLEAN ST_ContainsProperly (geom1 GEOMETRY, geom2 GEOMETRY)
```

Description Returns true if the first geometry "properly" contains the second geometry

In contrast to `ST_Contains`, this function does not return true if `geom2` is contained strictly on the boundary of `geom1`. A geometry always `ST_Contains` itself, but does not `ST_ContainsProperly` itself.

ST_ConvexHull

Signature

```
GEOMETRY ST_ConvexHull (geom GEOMETRY)
```

Description Returns the convex hull enclosing the geometry

ST_CoverageInvalidEdges

Signatures

```
GEOMETRY ST_CoverageInvalidEdges (geoms GEOMETRY[], tolerance DOUBLE)
GEOMETRY ST_CoverageInvalidEdges (geoms GEOMETRY[])
```

Description Returns the invalid edges in a polygonal coverage, which are edges that are not shared by two polygons. Returns NULL if the input is not a polygonal coverage, or if the input is valid. Tolerance is 0 by default.

ST_CoverageSimplify

Signatures

```
GEOMETRY ST_CoverageSimplify (geoms GEOMETRY[], tolerance DOUBLE, simplify_boundary BOOLEAN)
GEOMETRY ST_CoverageSimplify (geoms GEOMETRY[], tolerance DOUBLE)
```

Description Simplify the edges in a polygonal coverage, preserving the coverage by ensuring that there are no seams between the resulting simplified polygons.

By default, the boundary of the coverage is also simplified, but this can be controlled with the optional third 'simplify_boundary' parameter.

ST_CoverageUnion

Signature

```
GEOMETRY ST_CoverageUnion (geoms GEOMETRY[])
```

Description Union all geometries in a polygonal coverage into a single geometry. This may be faster than using `ST_Union`, but may use more memory.

ST_CoveredBy

Signature

```
BOOLEAN ST_CoveredBy (geom1 GEOMETRY, geom2 GEOMETRY)
```

Description Returns true if geom1 is ”covered by” geom2

ST_Covers

Signature

```
BOOLEAN ST_Covers (geom1 GEOMETRY, geom2 GEOMETRY)
```

Description Returns true if the geom1 ”covers” geom2

ST_Crosses

Signature

```
BOOLEAN ST_Crosses (geom1 GEOMETRY, geom2 GEOMETRY)
```

Description Returns true if geom1 ”crosses” geom2

ST_DWithin

Signature

```
BOOLEAN ST_DWithin (geom1 GEOMETRY, geom2 GEOMETRY, distance DOUBLE)
```

Description Returns if two geometries are within a target distance of each-other

---

ST_DWithin_GEOS

Signature

```
BOOLEAN ST_DWithin_GEOS (geom1 GEOMETRY, geom2 GEOMETRY, distance DOUBLE)
```

Description Returns if two geometries are within a target distance of each-other

---

ST_DWithin_Spheroid

Signature

```
BOOLEAN ST_DWithin_Spheroid (p1 POINT_2D, p2 POINT_2D, distance DOUBLE)
```

Description Returns if two POINT_2D's are within a target distance in meters, using an ellipsoidal model of the earths surface

The input geometry is assumed to be in the EPSG:4326 coordinate system (WGS84), with [latitude, longitude] axis order and the distance is returned in meters. This function uses the GeographicLib library to solve the inverse geodesic problem, calculating the distance between two points using an ellipsoidal model of the earth. This is a highly accurate method for calculating the distance between two arbitrary points taking the curvature of the earths surface into account, but is also the slowest.

ST_Difference

Signature

```
GEOMETRY ST_Difference (geom1 GEOMETRY, geom2 GEOMETRY)
```

Description Returns the ”difference” between two geometries

ST_Dimension

Signature

```
INTEGER ST_Dimension (geom GEOMETRY)
```

Description Returns the ”topological dimension” of a geometry.

- For POINT and MULTIPOINT geometries, returns 0.
- For LINESTRING and MULTILINESTRING, returns 1.
- For POLYGON and MULTIPOLYGON, returns 2.
- For GEOMETRYCOLLECTION, returns the maximum dimension of the contained geometries, or 0 if the collection is empty.

Example

```
select st_dimension('POLYGON((0 0, 0 1, 1 1, 1 0, 0 0))'::geometry);
----
2
```

ST_Disjoint

Signature

```
BOOLEAN ST_Disjoint (geom1 GEOMETRY, geom2 GEOMETRY)
```

Description Returns true if the geometries are disjoint

ST_Distance

Signatures

```
DOUBLE ST_Distance (point1 POINT_2D, point2 POINT_2D)
DOUBLE ST_Distance (point POINT_2D, linestring LINESTRING_2D)
DOUBLE ST_Distance (linestring LINESTRING_2D, point POINT_2D)
DOUBLE ST_Distance (geom1 GEOMETRY, geom2 GEOMETRY)
```

Description Returns the planar distance between two geometries

Example

```
SELECT ST_Distance('POINT (0 0)'::GEOMETRY, 'POINT (3 4)'::GEOMETRY);
----
5.0

-- Z coordinates are ignored
SELECT ST_Distance('POINT Z (0 0 0)'::GEOMETRY, 'POINT Z (3 4 5)'::GEOMETRY);
----
5.0
```

ST_Distance_GEOS

Signature

```
DOUBLE ST_Distance_GEOS (geom1 GEOMETRY, geom2 GEOMETRY)
```

Description Returns the planar distance between two geometries

---

ST_Distance_Sphere

Signatures

```
DOUBLE ST_Distance_Sphere (geom1 GEOMETRY, geom2 GEOMETRY)
DOUBLE ST_Distance_Sphere (point1 POINT_2D, point2 POINT_2D)
```

Description Returns the haversine (great circle) distance between two geometries.

- Only supports POINT geometries.
- Returns the distance in meters.
- The input is expected to be in WGS84 (EPSG:4326) coordinates, using a [latitude, longitude] axis order.

ST_Distance_Spheroid

Signature

```
DOUBLE ST_Distance_Spheroid (p1 POINT_2D, p2 POINT_2D)
```

Description Returns the distance between two geometries in meters using an ellipsoidal model of the earths surface

The input geometry is assumed to be in the EPSG:4326 coordinate system (WGS84), with [latitude, longitude] axis order and the distance limit is expected to be in meters. This function uses the GeographicLib library to solve the inverse geodesic problem, calculating the distance between two points using an ellipsoidal model of the earth. This is a highly accurate method for calculating the distance between two arbitrary points taking the curvature of the earths surface into account, but is also the slowest.

Example

```
-- Note: the coordinates are in WGS84 and [latitude, longitude] axis order
-- What's the distance between New York and Amsterdam (JFK and AMS airport)?
SELECT st_distance_spheroid(
st_point(40.6446, -73.7797),
st_point(52.3130, 4.7725)
);
----
5863418.7459356235
-- Roughly 5863km!
```

ST_Dump

Signature

```
STRUCT(geom GEOMETRY, path INTEGER[])[] ST_Dump (geom GEOMETRY)
```

Description Dumps a geometry into a list of sub-geometries and their ”path” in the original geometry.

You can use the UNNEST(`res, recursive := true`) function to explode resulting list of structs into multiple rows.

Example

```
select st_dump('MULTIPOINT(1 2,3 4)'::geometry);
----
[{'geom': 'POINT(1 2)', 'path': [0]}, {'geom': 'POINT(3 4)', 'path': [1]}]

select unnest(st_dump('MULTIPOINT(1 2,3 4)'::geometry), recursive := true);
--
--   geom      path
--  geometry   int32[]
--
--  POINT (1 2)  [1]
--  POINT (3 4)  [2]
--
```

ST_EndPoint

Signatures

```
GEOMETRY ST_EndPoint (geom GEOMETRY)
POINT_2D ST_EndPoint (line LINESTRING_2D)
```

Description Returns the end point of a LINESTRING.

ST_Envelope

Signature

```
GEOMETRY ST_Envelope (geom GEOMETRY)
```

Description Returns the minimum bounding rectangle of a geometry as a polygon geometry

---

ST_Equals

Signature

```
BOOLEAN ST_Equals (geom1 GEOMETRY, geom2 GEOMETRY)
```

Description Returns true if the geometries are ”equal”

ST_Extent

Signatures

```
BOX_2D ST_Extent (geom GEOMETRY)
BOX_2D ST_Extent (wkb WKB_BLOB)
```

Description Returns the minimal bounding box enclosing the input geometry

---

ST_Extent_Approx

Signature

```
BOX_2DF ST_Extent_Approx (geom GEOMETRY)
```

Description Returns the approximate bounding box of a geometry, if available.

This function is only really used internally, and returns the cached bounding box of the geometry if it exists. This function may be removed or renamed in the future.

ST_ExteriorRing

Signatures

```
GEOMETRY ST_ExteriorRing (geom GEOMETRY)
LINESTRING_2D ST_ExteriorRing (polygon POLYGON_2D)
```

Description Returns the exterior ring (shell) of a polygon geometry.

ST_FlipCoordinates

Signatures

```
GEOMETRY ST_FlipCoordinates (geom GEOMETRY)
POINT_2D ST_FlipCoordinates (point POINT_2D)
LINESTRING_2D ST_FlipCoordinates (linestring LINESTRING_2D)
POLYGON_2D ST_FlipCoordinates (polygon POLYGON_2D)
BOX_2D ST_FlipCoordinates (box BOX_2D)
```

Description Returns a new geometry with the coordinates of the input geometry ”flipped” so that x = y and y = x

---

ST_Force2D

Signature

```
GEOMETRY ST_Force2D (geom GEOMETRY)
```

Description Forces the vertices of a geometry to have X and Y components

This function will drop any Z and M values from the input geometry, if present. If the input geometry is already 2D, it will be returned as is.

ST_Force3DM

Signature

```
GEOMETRY ST_Force3DM (geom GEOMETRY, m DOUBLE)
```

Description Forces the vertices of a geometry to have X, Y and M components

The following cases apply:

- If the input geometry has a Z component but no M component, the Z component will be replaced with the new M value.
- If the input geometry has a M component but no Z component, it will be returned as is.
- If the input geometry has both a Z component and a M component, the Z component will be removed.
- Otherwise, if the input geometry has neither a Z or M component, the new M value will be added to the vertices of the input geometry.

ST_Force3DZ

Signature

```
GEOMETRY ST_Force3DZ (geom GEOMETRY, z DOUBLE)
```

Description Forces the vertices of a geometry to have X, Y and Z components

The following cases apply:

- If the input geometry has a M component but no Z component, the M component will be replaced with the new Z value.
- If the input geometry has a Z component but no M component, it will be returned as is.
- If the input geometry has both a Z component and a M component, the M component will be removed.
- Otherwise, if the input geometry has neither a Z or M component, the new Z value will be added to the vertices of the input geometry.

ST_Force4D

Signature

```
GEOMETRY ST_Force4D (geom GEOMETRY, z DOUBLE, m DOUBLE)
```

Description Forces the vertices of a geometry to have X, Y, Z and M components

The following cases apply:

- If the input geometry has a Z component but no M component, the new M value will be added to the vertices of the input geometry.
- If the input geometry has a M component but no Z component, the new Z value will be added to the vertices of the input geometry.
- If the input geometry has both a Z component and a M component, the geometry will be returned as is.
- Otherwise, if the input geometry has neither a Z or M component, the new Z and M values will be added to the vertices of the input geometry.

ST_GeomFromGeoJSON

Signatures

```
GEOMETRY ST_GeomFromGeoJSON (geojson JSON)
GEOMETRY ST_GeomFromGeoJSON (geojson VARCHAR)
```

Description Deserializes a GEOMETRY from a GeoJSON fragment.

Example

```
SELECT ST_GeomFromGeoJSON('{"type":"Point","coordinates":[1.0,2.0]}');
----
POINT (1 2)
```

ST_GeomFromHEXEWKB

Signature

```
GEOMETRY ST_GeomFromHEXEWKB (hexwkb VARCHAR)
```

Description Deserialize a GEOMETRY from a HEX(E)WKB encoded string

DuckDB spatial doesn't currently differentiate between `WKB` and `EWKB`, so `ST_GeomFromHEXWKB` and `ST_GeomFromHEXEWKB` are just aliases of each other.

ST_GeomFromHEXWKB

Signature

```
GEOMETRY ST_GeomFromHEXWKB (hexwkb VARCHAR)
```

Description Deserialize a GEOMETRY from a HEX(E)WKB encoded string

DuckDB spatial doesn't currently differentiate between `WKB` and `EWKB`, so `ST_GeomFromHEXWKB` and `ST_GeomFromHEXEWKB` are just aliases of each other.

ST_GeomFromText

Signatures

```
GEOMETRY ST_GeomFromText (wkt VARCHAR)
GEOMETRY ST_GeomFromText (wkt VARCHAR, ignore_invalid BOOLEAN)
```

Description Deserialize a GEOMETRY from a WKT encoded string

ST_GeomFromWKB

Signatures

```
GEOMETRY ST_GeomFromWKB (wkb WKB_BLOB)
GEOMETRY ST_GeomFromWKB (blob BLOB)
```

Description Deserializes a GEOMETRY from a WKB encoded blob

ST_GeometryType

Signatures

```
ANY ST_GeometryType (geom GEOMETRY)
ANY ST_GeometryType (point POINT_2D)
ANY ST_GeometryType (linestring LINESTRING_2D)
ANY ST_GeometryType (polygon POLYGON_2D)
ANY ST_GeometryType (wkb WKB_BLOB)
```

Description Returns a 'GEOMETRY_TYPE' enum identifying the input geometry type. Possible enum return types are: `POINT`, `LINESTRING`, `POLYGON`, `MULTIPOINT`, `MULTILINESTRING`, `MULTIPOLYGON` and `GEOMETRYCOLLECTION`.

Example

```
SELECT DISTINCT ST_GeometryType(ST_GeomFromText('POINT(1 1)'));
----
POINT
```

ST_HasM

Signatures

```
BOOLEAN ST_HasM (geom GEOMETRY)
BOOLEAN ST_HasM (wkb WKB_BLOB)
```

Description Check if the input geometry has M values.

Example

```
-- HasM for a 2D geometry
SELECT ST_HasM(ST_GeomFromText('POINT(1 1)'));
----
false

-- HasM for a 3DZ geometry
SELECT ST_HasM(ST_GeomFromText('POINT Z(1 1 1)'));
----
false

-- HasM for a 3DM geometry
SELECT ST_HasM(ST_GeomFromText('POINT M(1 1 1)'));
```

```
----
true

-- HasM for a 4D geometry
SELECT ST_HasM(ST_GeomFromText('POINT ZM(1 1 1 1)'));
----
true
```

ST_HasZ

Signatures

```
BOOLEAN ST_HasZ (geom GEOMETRY)
BOOLEAN ST_HasZ (wkb WKB_BLOB)
```

Description Check if the input geometry has Z values.

Example

```
-- HasZ for a 2D geometry
SELECT ST_HasZ(ST_GeomFromText('POINT(1 1)'));
----
false

-- HasZ for a 3DZ geometry
SELECT ST_HasZ(ST_GeomFromText('POINT Z(1 1 1)'));
----
true

-- HasZ for a 3DM geometry
SELECT ST_HasZ(ST_GeomFromText('POINT M(1 1 1)'));
----
false

-- HasZ for a 4D geometry
SELECT ST_HasZ(ST_GeomFromText('POINT ZM(1 1 1 1)'));
----
true
```

ST_Hilbert

Signatures

```
UINTEGER ST_Hilbert (x DOUBLE, y DOUBLE, bounds BOX_2D)
UINTEGER ST_Hilbert (geom GEOMETRY, bounds BOX_2D)
UINTEGER ST_Hilbert (geom GEOMETRY)
UINTEGER ST_Hilbert (box BOX_2D, bounds BOX_2D)
UINTEGER ST_Hilbert (box BOX_2DF, bounds BOX_2DF)
```

Description Encodes the X and Y values as the hilbert curve index for a curve covering the given bounding box. If a geometry is provided, the center of the approximate bounding box is used as the point to encode. If no bounding box is provided, the hilbert curve index is mapped to the full range of a single-presicion float. For the BOX_2D and BOX_2DF variants, the center of the box is used as the point to encode.

ST_InterpolatePoint

Signature

```
DOUBLE ST_InterpolatePoint (line GEOMETRY, point GEOMETRY)
```

Description Computes the closest point on a LINESTRING to a given POINT and returns the interpolated M value of that point.

First argument must be a linestring and must have a M dimension. The second argument must be a point. Neither argument can be empty.

ST_Intersection

Signature

```
GEOMETRY ST_Intersection (geom1 GEOMETRY, geom2 GEOMETRY)
```

Description Returns the intersection of two geometries

ST_Intersects

Signatures

```
BOOLEAN ST_Intersects (box1 BOX_2D, box2 BOX_2D)
BOOLEAN ST_Intersects (geom1 GEOMETRY, geom2 GEOMETRY)
```

Description Returns true if the geometries intersect

ST_Intersects_Extent

Signature

```
BOOLEAN ST_Intersects_Extent (geom1 GEOMETRY, geom2 GEOMETRY)
```

Description Returns true if the extent of two geometries intersects

---

ST_IsClosed

Signature

```
BOOLEAN ST_IsClosed (geom GEOMETRY)
```

Description Check if a geometry is 'closed'

ST_IsEmpty

Signatures

```
BOOLEAN ST_IsEmpty (geom GEOMETRY)
BOOLEAN ST_IsEmpty (linestring LINESTRING_2D)
BOOLEAN ST_IsEmpty (polygon POLYGON_2D)
```

Description Returns true if the geometry is ”empty”.

ST_IsRing

Signature

```
BOOLEAN ST_IsRing (geom GEOMETRY)
```

Description Returns true if the geometry is a ring (both ST_IsClosed and ST_IsSimple).

ST_IsSimple

Signature

```
BOOLEAN ST_IsSimple (geom GEOMETRY)
```

Description Returns true if the geometry is simple

ST_IsValid

Signature

```
BOOLEAN ST_IsValid (geom GEOMETRY)
```

Description Returns true if the geometry is valid

ST_Length

Signatures

```
DOUBLE ST_Length (geom GEOMETRY)
DOUBLE ST_Length (linestring LINESTRING_2D)
```

Description Returns the length of the input line geometry

ST_Length_Spheroid

Signatures

```
DOUBLE ST_Length_Spheroid (geom GEOMETRY)
DOUBLE ST_Length_Spheroid (line LINESTRING_2D)
```

Description Returns the length of the input geometry in meters, using an ellipsoidal model of the earth

The input geometry is assumed to be in the EPSG:4326 coordinate system (WGS84), with [latitude, longitude] axis order and the length is returned in meters. This function uses the GeographicLib library, calculating the length using an ellipsoidal model of the earth. This is a highly accurate method for calculating the length of a line geometry taking the curvature of the earth into account, but is also the slowest.

Returns `0.0` for any geometry that is not a `LINESTRING`, `MULTILINESTRING` or `GEOMETRYCOLLECTION` containing line geometries.

ST_LineInterpolatePoint

Signature

```
GEOMETRY ST_LineInterpolatePoint (line GEOMETRY, fraction DOUBLE)
```

Description Returns a point interpolated along a line at a fraction of total 2D length.

ST_LineInterpolatePoints

Signature

```
GEOMETRY ST_LineInterpolatePoints (line GEOMETRY, fraction DOUBLE, repeat BOOLEAN)
```

Description Returns a multi-point interpolated along a line at a fraction of total 2D length.

if repeat is false, the result is a single point, (and equivalent to ST_LineInterpolatePoint), otherwise, the result is a multi-point with points repeated at the fraction interval.

ST_LineLocatePoint

Signature

```
DOUBLE ST_LineLocatePoint (line GEOMETRY, point GEOMETRY)
```

Description Returns the location on a line closest to a point as a fraction of the total 2D length of the line.

ST_LineMerge

Signatures

```
GEOMETRY ST_LineMerge (geom GEOMETRY)
GEOMETRY ST_LineMerge (geom GEOMETRY, preserve_direction BOOLEAN)
```

Description ”Merges” the input line geometry, optionally taking direction into account.

ST_LineString2DFromWKB

Signature

```
GEOMETRY ST_LineString2DFromWKB (linestring LINESTRING_2D)
```

Description Deserialize a LINESTRING_2D from a WKB encoded blob

---

ST_LineSubstring

Signature

```
GEOMETRY ST_LineSubstring (line GEOMETRY, start_fraction DOUBLE, end_fraction DOUBLE)
```

Description Returns a substring of a line between two fractions of total 2D length.

ST_LocateAlong

Signatures

```
GEOMETRY ST_LocateAlong (line GEOMETRY, measure DOUBLE, offset DOUBLE)
GEOMETRY ST_LocateAlong (line GEOMETRY, measure DOUBLE)
```

Description Returns a point or multi-point, containing the point(s) at the geometry with the given measure

For a LINESTRING, or MULTILINESTRING, the location is determined by interpolating between M values For a POINT and MULTIPOINT, the point is returned if the measure matches the M value of the vertex, otherwise an empty geometry is returned For a POLYGON, only the exterior ring is considered, and treated as a LINESTRING

If offset is provided, the resulting point(s) is offset by the given amount perpendicular to the line direction.

ST_LocateBetween

Signatures

```
GEOMETRY ST_LocateBetween (line GEOMETRY, start_measure DOUBLE, end_measure DOUBLE, offset DOUBLE)
GEOMETRY ST_LocateBetween (line GEOMETRY, start_measure DOUBLE, end_measure DOUBLE)
```

Description Returns a geometry or geometry collection created by filtering and interpolating vertices within a range of ”M” values

Creates a geometry or geometry collection, containing the parts formed by vertices that have an ”M” value within the ”start_measure” and ”end_measure” range

For LINESTRING or MULTILINESTRING, if a line segment would cross either the upper or lower bound, a vertex is added by interpolating the coordinates at the ”intersection” For a POINT and MULTIPOINT, the point is added to the collection if its vertex has an ”M” value within the range, otherwise it is skipped For a POLYGON, only the exterior ring is considered, and treated like a LINESTRING

If offset is provided, the resulting vertices are offset by the given amount perpendicular to the line direction.

ST_M

Signature

```
DOUBLE ST_M (geom GEOMETRY)
```

Description Returns the M coordinate of a point geometry

Example

```
SELECT ST_M(ST_Point(1, 2, 3, 4))
```

ST_MMax

Signature

```
DOUBLE ST_MMax (geom GEOMETRY)
```

Description Returns the maximum M coordinate of a geometry

Example

```
SELECT ST_MMax(ST_Point(1, 2, 3, 4))
```

ST_MMin

Signature

```
DOUBLE ST_MMin (geom GEOMETRY)
```

Description Returns the minimum M coordinate of a geometry

Example

```
SELECT ST_MMin(ST_Point(1, 2, 3, 4))
```

ST_MakeBox2D

Signature

```
BOX_2D ST_MakeBox2D (point1 GEOMETRY, point2 GEOMETRY)
```

Description Create a BOX2D from two POINT geometries

Example

```
SELECT ST_MakeBox2D(ST_Point(0, 0), ST_Point(1, 1));
----
BOX(0 0, 1 1)
```

ST_MakeEnvelope

Signature

```
GEOMETRY ST_MakeEnvelope (min_x DOUBLE, min_y DOUBLE, max_x DOUBLE, max_y DOUBLE)
```

Description Create a rectangular polygon from min/max coordinates

---

ST_MakeLine

Signatures

```
GEOMETRY ST_MakeLine (geoms GEOMETRY[])
GEOMETRY ST_MakeLine (start GEOMETRY, end GEOMETRY)
```

Description Create a LINESTRING from a list of POINT geometries

Example

```
SELECT ST_MakeLine([ST_Point(0, 0), ST_Point(1, 1)]);
----
LINESTRING(0 0, 1 1)
```

ST_MakePoint

Signatures

```
POINT_2D ST_MakePoint (x DOUBLE, y DOUBLE)
POINT_3D ST_MakePoint (x DOUBLE, y DOUBLE, z DOUBLE)
POINT_4D ST_MakePoint (x DOUBLE, y DOUBLE, z DOUBLE, m DOUBLE)
```

Description Creates a GEOMETRY point from an pair of floating point numbers.

For geodetic coordinate systems, x is typically the longitude value and y is the latitude value.

Note that ST_Point is equivalent. ST_MakePoint is provided for PostGIS compatibility.

Example

```
SELECT ST_AsText(ST_MakePoint(143.3, -24.2));
----
POINT (143.3 -24.2)
```

ST_MakePolygon

Signatures

```
GEOMETRY ST_MakePolygon (shell GEOMETRY)
GEOMETRY ST_MakePolygon (shell GEOMETRY, holes GEOMETRY[])
```

Description Create a POLYGON from a LINESTRING shell

Example

```
SELECT ST_MakePolygon(ST_LineString([ST_Point(0, 0), ST_Point(1, 0), ST_Point(1, 1), ST_Point(0, 0)]));
```

ST_MakeValid

Signature

```
GEOMETRY ST_MakeValid (geom GEOMETRY)
```

Description Returns a valid representation of the geometry

ST_MaximumInscribedCircle

Signatures

```
STRUCT(center GEOMETRY, nearest GEOMETRY, radius DOUBLE) ST_MaximumInscribedCircle (geom GEOMETRY)
STRUCT(center GEOMETRY, nearest GEOMETRY, radius DOUBLE) ST_MaximumInscribedCircle (geom GEOMETRY,
tolerance DOUBLE)
```

Description Returns the maximum inscribed circle of the input geometry, optionally with a tolerance.

By default, the tolerance is computed as `max(width, height) / 1000`. The return value is a struct with the center of the circle, the nearest point to the center on the boundary of the geometry and the radius of the circle.

Example

```
-- Find the maximum inscribed circle of a square
SELECT ST_MaximumInscribedCircle(
    ST_GeomFromText('POLYGON((0 0, 10 0, 10 10, 0 10, 0 0))')
);
----
{'center': POINT (5 5), 'nearest': POINT (5 0), 'radius': 5.0}
```

ST_MinimumRotatedRectangle

Signature

```
GEOMETRY ST_MinimumRotatedRectangle (geom GEOMETRY)
```

Description Returns the minimum rotated rectangle that bounds the input geometry, finding the surrounding box that has the lowest area by using a rotated rectangle, rather than taking the lowest and highest coordinate values as per ST_Envelope().

ST_Multi

Signature

```
GEOMETRY ST_Multi (geom GEOMETRY)
```

Description Turns a single geometry into a multi geometry.

If the geometry is already a multi geometry, it is returned as is.

Example

```
SELECT ST_Multi(ST_GeomFromText('POINT(1 2)'));
----
MULTIPOINT (1 2)

SELECT ST_Multi(ST_GeomFromText('LINESTRING(1 1, 2 2)'));
----
MULTILINESTRING ((1 1, 2 2))

SELECT ST_Multi(ST_GeomFromText('POLYGON((0 0, 0 1, 1 1, 1 0, 0 0))'));
----
MULTIPOLYGON (((0 0, 0 1, 1 1, 1 0, 0 0)))
```

ST_NGeometries

Signature

```
INTEGER ST_NGeometries (geom GEOMETRY)
```

Description Returns the number of component geometries in a collection geometry. If the input geometry is not a collection, this function returns 0 or 1 depending on if the geometry is empty or not.

ST_NInteriorRings

Signatures

```
INTEGER ST_NInteriorRings (geom GEOMETRY)
INTEGER ST_NInteriorRings (polygon POLYGON_2D)
```

Description Returns the number of interior rings of a polygon

---

ST_NPoints

Signatures

```
UINTEGER ST_NPoints (geom GEOMETRY)
UBIGINT ST_NPoints (point POINT_2D)
UBIGINT ST_NPoints (linestring LINESTRING_2D)
UBIGINT ST_NPoints (polygon POLYGON_2D)
UBIGINT ST_NPoints (box BOX_2D)
```

Description Returns the number of vertices within a geometry

ST_Node

Signature

```
GEOMETRY ST_Node (geom GEOMETRY)
```

Description Returns a ”noded” MultiLinestring, produced by combining a collection of input linestrings and adding additional vertices where they intersect.

Example

```
-- Create a noded multilinestring from two intersecting lines
SELECT ST_Node(
    ST_GeomFromText('MULTILINESTRING((0 0, 2 2), (0 2, 2 0))')
);
----
MULTILINESTRING ((0 0, 1 1), (1 1, 2 2), (0 2, 1 1), (1 1, 2 0))
```

ST_Normalize

Signature

```
GEOMETRY ST_Normalize (geom GEOMETRY)
```

Description Returns the ”normalized” representation of the geometry

---

ST_NumGeometries

Signature

```
INTEGER ST_NumGeometries (geom GEOMETRY)
```

Description Returns the number of component geometries in a collection geometry. If the input geometry is not a collection, this function returns 0 or 1 depending on if the geometry is empty or not.

ST_NumInteriorRings

Signatures

```
INTEGER ST_NumInteriorRings (geom GEOMETRY)
INTEGER ST_NumInteriorRings (polygon POLYGON_2D)
```

Description Returns the number of interior rings of a polygon

---

ST_NumPoints

Signatures

```
UINTEGER ST_NumPoints (geom GEOMETRY)
UBIGINT ST_NumPoints (point POINT_2D)
UBIGINT ST_NumPoints (linestring LINESTRING_2D)
UBIGINT ST_NumPoints (polygon POLYGON_2D)
UBIGINT ST_NumPoints (box BOX_2D)
```

Description Returns the number of vertices within a geometry

ST_Overlaps

Signature

```
BOOLEAN ST_Overlaps (geom1 GEOMETRY, geom2 GEOMETRY)
```

Description Returns true if the geometries overlap

ST_Perimeter

Signatures

```
DOUBLE ST_Perimeter (geom GEOMETRY)
DOUBLE ST_Perimeter (polygon POLYGON_2D)
DOUBLE ST_Perimeter (box BOX_2D)
```

Description Returns the length of the perimeter of the geometry

---

ST_Perimeter_Spheroid

Signatures

```
DOUBLE ST_Perimeter_Spheroid (geom GEOMETRY)
DOUBLE ST_Perimeter_Spheroid (poly POLYGON_2D)
```

Description Returns the length of the perimeter in meters using an ellipsoidal model of the earths surface

The input geometry is assumed to be in the EPSG:4326 coordinate system (WGS84), with [latitude, longitude] axis order and the length is returned in meters. This function uses the GeographicLib library, calculating the perimeter using an ellipsoidal model of the earth. This is a highly accurate method for calculating the perimeter of a polygon taking the curvature of the earth into account, but is also the slowest.

Returns `0.0` for any geometry that is not a `POLYGON`, `MULTIPOLYGON` or `GEOMETRYCOLLECTION` containing polygon geometries.

ST_Point

Signature

```
GEOMETRY ST_Point (x DOUBLE, y DOUBLE)
```

Description Creates a GEOMETRY point

ST_Point2D

Signature

```
POINT_2D ST_Point2D (x DOUBLE, y DOUBLE)
```

Description Creates a POINT_2D

ST_Point2DFromWKB

Signature

```
GEOMETRY ST_Point2DFromWKB (point POINT_2D)
```

Description Deserialize a POINT_2D from a WKB encoded blob

ST_Point3D

Signature

```
POINT_3D ST_Point3D (x DOUBLE, y DOUBLE, z DOUBLE)
```

Description Creates a POINT_3D

ST_Point4D

Signature

```
POINT_4D ST_Point4D (x DOUBLE, y DOUBLE, z DOUBLE, m DOUBLE)
```

Description Creates a POINT_4D

ST_PointN

Signatures

```
GEOMETRY ST_PointN (geom GEOMETRY, index INTEGER)
POINT_2D ST_PointN (linestring LINESTRING_2D, index INTEGER)
```

Description Returns the n'th vertex from the input geometry as a point geometry

---

ST_PointOnSurface

Signature

```
GEOMETRY ST_PointOnSurface (geom GEOMETRY)
```

Description Returns a point guaranteed to lie on the surface of the geometry

---

ST_Points

Signature

```
GEOMETRY ST_Points (geom GEOMETRY)
```

Description Collects all the vertices in the geometry into a MULTIPOINT

Example

```
select st_points('LINESTRING(1 1, 2 2)'::geometry);
----
MULTIPOINT (1 1, 2 2)

select st_points('MULTIPOLYGON Z EMPTY'::geometry);
----
MULTIPOINT Z EMPTY
```

ST_Polygon2DFromWKB

Signature

```
GEOMETRY ST_Polygon2DFromWKB (polygon POLYGON_2D)
```

Description Deserialize a POLYGON_2D from a WKB encoded blob

ST_Polygonize

Signature

```
GEOMETRY ST_Polygonize (geometries GEOMETRY[])
```

Description Returns a polygonized representation of the input geometries

Example

```
-- Create a polygon from a closed linestring ring
SELECT ST_Polygonize([
    ST_GeomFromText('LINESTRING(0 0, 0 10, 10 10, 10 0, 0 0)')
]);
```

```
GEOMETRYCOLLECTION (POLYGON ((0 0, 0 10, 10 10, 10 0, 0 0)))
```

ST_QuadKey

Signatures

```
VARCHAR ST_QuadKey (longitude DOUBLE, latitude DOUBLE, level INTEGER)
VARCHAR ST_QuadKey (point GEOMETRY, level INTEGER)
```

Description Compute the quadkey for a given lon/lat point at a given level. Note that the parameter order is **longitude**, **latitude**.

`level` has to be between 1 and 23, inclusive.

The input coordinates will be clamped to the lon/lat bounds of the earth (longitude between -180 and 180, latitude between -85.05112878 and 85.05112878).

The geometry overload throws an error if the input geometry is not a `POINT`

Example

```
SELECT ST_QuadKey(st_point(11.08, 49.45), 10);
----
1333203202
```

ST_ReducePrecision

Signature

```
GEOMETRY ST_ReducePrecision (geom GEOMETRY, precision DOUBLE)
```

Description Returns the geometry with all vertices reduced to the given precision

---

ST_RemoveRepeatedPoints

Signatures

```
LINESTRING_2D ST_RemoveRepeatedPoints (line LINESTRING_2D)
LINESTRING_2D ST_RemoveRepeatedPoints (line LINESTRING_2D, tolerance DOUBLE)
GEOMETRY ST_RemoveRepeatedPoints (geom GEOMETRY)
GEOMETRY ST_RemoveRepeatedPoints (geom GEOMETRY, tolerance DOUBLE)
```

Description Remove repeated points from a LINESTRING.

ST_Reverse

Signature

```
GEOMETRY ST_Reverse (geom GEOMETRY)
```

Description Returns the geometry with the order of its vertices reversed

---

ST_ShortestLine

Signature

```
GEOMETRY ST_ShortestLine (geom1 GEOMETRY, geom2 GEOMETRY)
```

Description Returns the shortest line between two geometries

ST_Simplify

Signature

```
GEOMETRY ST_Simplify (geom GEOMETRY, tolerance DOUBLE)
```

Description Returns a simplified version of the geometry

ST_SimplifyPreserveTopology

Signature

```
GEOMETRY ST_SimplifyPreserveTopology (geom GEOMETRY, tolerance DOUBLE)
```

Description Returns a simplified version of the geometry that preserves topology

---

ST_StartPoint

Signatures

```
GEOMETRY ST_StartPoint (geom GEOMETRY)
POINT_2D ST_StartPoint (line LINESTRING_2D)
```

Description Returns the start point of a LINESTRING.

ST_TileEnvelope

Signature

```
GEOMETRY ST_TileEnvelope (tile_zoom INTEGER, tile_x INTEGER, tile_y INTEGER)
```

Description The `ST_TileEnvelope` scalar function generates tile envelope rectangular polygons from specified zoom level and tile indices.

This is used in MVT generation to select the features corresponding to the tile extent. The envelope is in the Web Mercator coordinate reference system (EPSG:3857). The tile pyramid starts at zoom level 0, corresponding to a single tile for the world. Each zoom level doubles the number of tiles in each direction, such that zoom level 1 is 2 tiles wide by 2 tiles high, zoom level 2 is 4 tiles wide by 4 tiles high, and so on. Tile indices start at `[x=0, y=0]` at the top left, and increase down and right. For example, at zoom level 2, the top right tile is `[x=3, y=0]`, the bottom left tile is `[x=0, y=3]`, and the bottom right is `[x=3, y=3]`.

```
SELECT ST_TileEnvelope(2, 3, 1);
```

Example

```
SELECT ST_TileEnvelope(2, 3, 1);
```

```
┌──────────────
```

ST_Transform

Signatures

```
BOX_2D ST_Transform (box BOX_2D, source_crs VARCHAR, target_crs VARCHAR)
BOX_2D ST_Transform (box BOX_2D, source_crs VARCHAR, target_crs VARCHAR, always_xy BOOLEAN)
POINT_2D ST_Transform (point POINT_2D, source_crs VARCHAR, target_crs VARCHAR)
POINT_2D ST_Transform (point POINT_2D, source_crs VARCHAR, target_crs VARCHAR, always_xy BOOLEAN)
GEOMETRY ST_Transform (geom GEOMETRY, source_crs VARCHAR, target_crs VARCHAR)
GEOMETRY ST_Transform (geom GEOMETRY, source_crs VARCHAR, target_crs VARCHAR, always_xy BOOLEAN)
```

Description Transforms a geometry between two coordinate systems

The source and target coordinate systems can be specified using any format that the PROJ library supports.

The third optional `always_xy` parameter can be used to force the input and output geometries to be interpreted as having a [easting, northing] coordinate axis order regardless of what the source and target coordinate system definition says. This is particularly useful when transforming to/from the WGS84/EPSG:4326 coordinate system (what most people think of when they hear "longitude"/"latitude" or "GPS coordinates"), which is defined as having a [latitude, longitude] axis order even though [longitude, latitude] is commonly used in practice (e.g. in GeoJSON). More details available in the PROJ documentation.

DuckDB spatial vendors its own static copy of the PROJ database of coordinate systems, so if you have your own installation of PROJ on your system the available coordinate systems may differ to what's available in other GIS software.

Example

```
-- Transform a geometry from EPSG:4326 to EPSG:3857 (WGS84 to WebMercator)
-- Note that since WGS84 is defined as having a [latitude, longitude] axis order
-- we follow the standard and provide the input geometry using that axis order,
-- but the output will be [easting, northing] because that is what's defined by
-- WebMercator.

SELECT
    ST_Transform(
        st_point(52.373123, 4.892360),
        'EPSG:4326',
        'EPSG:3857'
    );
----
POINT (544615.0239773799 6867874.103539125)

-- Alternatively, let's say we got our input point from e.g. a GeoJSON file,
-- which uses WGS84 but with [longitude, latitude] axis order. We can use the
-- `always_xy` parameter to force the input geometry to be interpreted as having
-- a [northing, easting] axis order instead, even though the source coordinate
-- reference system definition (WGS84) says otherwise.

SELECT
    ST_Transform(
        -- note the axis order is reversed here
        st_point(4.892360, 52.373123),
        'EPSG:4326',
        'EPSG:3857',
        always_xy := true
    );
----
POINT (544615.0239773799 6867874.103539125)

-- Transform a geometry from OSG36 British National Grid EPSG:27700 to EPSG:4326 WGS84
```

```
-- Standard transform is often fine for the first few decimal places before being wrong
-- which could result in an error starting at about 10m and possibly much more
SELECT ST_Transform(bng, 'EPSG:27700', 'EPSG:4326', xy := true) AS without_grid_file

```

ST_Union

Signature

```
GEOMETRY ST_Union (geom1 GEOMETRY, geom2 GEOMETRY)
```

Description Returns the union of two geometries

ST_VoronoiDiagram

Signature

```
GEOMETRY ST_VoronoiDiagram (geom GEOMETRY)
```

Description Returns the Voronoi diagram of the supplied MultiPoint geometry

---

ST_Within

Signatures

```
BOOLEAN ST_Within (geom1 POINT_2D, geom2 POLYGON_2D)
BOOLEAN ST_Within (geom1 GEOMETRY, geom2 GEOMETRY)
```

Description Returns true if the first geometry is within the second

---

ST_WithinProperly

Signature

```
BOOLEAN ST_WithinProperly (geom1 GEOMETRY, geom2 GEOMETRY)
```

Description Returns true if the first geometry "properly" is contained by the second geometry

This function functions the same as `ST_ContainsProperly`, but the arguments are swapped.

ST_X

Signatures

```
DOUBLE ST_X (geom GEOMETRY)
DOUBLE ST_X (point POINT_2D)
```

Description Returns the X coordinate of a point geometry

Example

```
SELECT ST_X(ST_Point(1, 2))
```

ST_XMax

Signatures

```
DOUBLE ST_XMax (geom GEOMETRY)
DOUBLE ST_XMax (point POINT_2D)
DOUBLE ST_XMax (line LINESTRING_2D)
DOUBLE ST_XMax (polygon POLYGON_2D)
DOUBLE ST_XMax (box BOX_2D)
FLOAT ST_XMax (box BOX_2DF)
```

Description Returns the maximum X coordinate of a geometry

Example

```
SELECT ST_XMax(ST_Point(1, 2))
```

ST_XMin

Signatures

```
DOUBLE ST_XMin (geom GEOMETRY)
DOUBLE ST_XMin (point POINT_2D)
DOUBLE ST_XMin (line LINESTRING_2D)
DOUBLE ST_XMin (polygon POLYGON_2D)
DOUBLE ST_XMin (box BOX_2D)
FLOAT ST_XMin (box BOX_2DF)
```

Description Returns the minimum X coordinate of a geometry

Example

```
SELECT ST_XMin(ST_Point(1, 2))
```

ST_Y

Signatures

```
DOUBLE ST_Y (geom GEOMETRY)
DOUBLE ST_Y (point POINT_2D)
```

Description Returns the Y coordinate of a point geometry

Example

```
SELECT ST_Y(ST_Point(1, 2))
```

ST_YMax

Signatures

```
DOUBLE ST_YMax (geom GEOMETRY)
DOUBLE ST_YMax (point POINT_2D)
DOUBLE ST_YMax (line LINESTRING_2D)
DOUBLE ST_YMax (polygon POLYGON_2D)
DOUBLE ST_YMax (box BOX_2D)
FLOAT ST_YMax (box BOX_2DF)
```

Description Returns the maximum Y coordinate of a geometry

Example

```
SELECT ST_YMax(ST_Point(1, 2))
```

ST_YMin

Signatures

```
DOUBLE ST_YMin (geom GEOMETRY)
DOUBLE ST_YMin (point POINT_2D)
DOUBLE ST_YMin (line LINESTRING_2D)
DOUBLE ST_YMin (polygon POLYGON_2D)
DOUBLE ST_YMin (box BOX_2D)
FLOAT ST_YMin (box BOX_2DF)
```

Description Returns the minimum Y coordinate of a geometry

Example

```
SELECT ST_YMin(ST_Point(1, 2))
```

ST_Z

Signature

```
DOUBLE ST_Z (geom GEOMETRY)
```

Description Returns the Z coordinate of a point geometry

Example

```
SELECT ST_Z(ST_Point(1, 2, 3))
```

ST_ZMFlag

Signatures

```
UTINYINT ST_ZMFlag (geom GEOMETRY)
UTINYINT ST_ZMFlag (wkb WKB_BLOB)
```

Description Returns a flag indicating the presence of Z and M values in the input geometry. 0 = No Z or M values 1 = M values only 2 = Z values only 3 = Z and M values

Example

```
-- ZMFlag for a 2D geometry
SELECT ST_ZMFlag(ST_GeomFromText('POINT(1 1)'));
----
0

-- ZMFlag for a 3DZ geometry
SELECT ST_ZMFlag(ST_GeomFromText('POINT Z(1 1 1)'));
----
2

-- ZMFlag for a 3DM geometry
SELECT ST_ZMFlag(ST_GeomFromText('POINT M(1 1 1)'));
----
1

-- ZMFlag for a 4D geometry
SELECT ST_ZMFlag(ST_GeomFromText('POINT ZM(1 1 1 1)'));
----
3
```

ST_ZMax

Signature

```
DOUBLE ST_ZMax (geom GEOMETRY)
```

Description Returns the maximum Z coordinate of a geometry

Example

```
SELECT ST_ZMax(ST_Point(1, 2, 3))
```

ST_ZMin

Signature

```
DOUBLE ST_ZMin (geom GEOMETRY)
```

Description Returns the minimum Z coordinate of a geometry

Example

```
SELECT ST_ZMin(ST_Point(1, 2, 3))
```

Aggregate Functions

ST_AsMVT

Signatures

```
BLOB ST_AsMVT (col0 ANY)
BLOB ST_AsMVT (col0 ANY, col1 VARCHAR)
BLOB ST_AsMVT (col0 ANY, col1 VARCHAR, col2 INTEGER)
BLOB ST_AsMVT (col0 ANY, col1 VARCHAR, col2 INTEGER, col3 VARCHAR)
BLOB ST_AsMVT (col0 ANY, col1 VARCHAR, col2 INTEGER, col3 VARCHAR, col4 VARCHAR)
```

Description Make a Mapbox Vector Tile from a set of geometries and properties The function takes as input a row type (STRUCT) containing a geometry column and any number of property columns. It returns a single binary BLOB containing the Mapbox Vector Tile.

The function has the following signature:

```
ST_AsMVT(row STRUCT, layer_name VARCHAR DEFAULT 'layer', extent INTEGER DEFAULT 4096, geom_column_name VARCHAR DEFAULT NULL, feature_id_column_name VARCHAR DEFAULT NULL) -> BLOB
```

- The first argument is a struct containing the geometry and properties.
- The second argument is the name of the layer in the vector tile. This argument is optional and defaults to 'layer'.
- The third argument is the extent of the tile. This argument is optional and defaults to 4096.
- The fourth argument is the name of the geometry column in the input row. This argument is optional. If not provided, the first geometry column in the input row will be used. If multiple geometry columns are present, an error will be raised.

- The fifth argument is the name of the feature id column in the input row. This argument is optional. If provided, the values in this column will be used as feature ids in the vector tile. The column must be of type INTEGER or BIGINT. If set to negative or NULL, a feature id will not be assigned to the corresponding feature.

The input struct must contain exactly one geometry column of type GEOMETRY. It can contain any number of property columns of types VARCHAR, FLOAT, DOUBLE, INTEGER, BIGINT, or BOOLEAN.

Example:

```
SELECT ST_AsMVT({'geom': geom, 'id': id, 'name': name}, 'cities', 4096, 'geom', 'id') AS tile
FROM cities;
```

This example creates a vector tile named 'cities' with an extent of 4096 from the 'cities' table, using 'geom' as the geometry column and 'id' as the feature id column.

However, you probably want to use the ST_AsMVTGeom function to first transform and clip your geometries to the tile extent. The following example assumes the geometry is in WebMercator (”EPSG:3857”) coordinates. Replace <z>{:.language-sql .highlight}, <x>{:.language-sql .highlight}, and <y>{:.language-sql .highlight} with the appropriate tile coordinates, <your_table>{:.language-sql .highlight} with your table name, and <tile_path> with the path to write the tile to.

```
COPY (
    SELECT ST_AsMVT({
        "geometry": ST_AsMVTGeom(
            geometry,
            ST_Extent(ST_TileEnvelope(<z>, <x>, <y>)),
            4096,
            256,
            false
        )
    })
    FROM <your_table> WHERE ST_Intersects(geometry, ST_TileEnvelope(<z>, <x>, <y>))
) to <tile_path> (FORMAT 'BLOB');
```

ST_CoverageInvalidEdges_Agg

Signatures

```
GEOMETRY ST_CoverageInvalidEdges_Agg (col0 GEOMETRY)
GEOMETRY ST_CoverageInvalidEdges_Agg (col0 GEOMETRY, col1 DOUBLE)
```

Description Returns the invalid edges of a coverage geometry

ST_CoverageSimplify_Agg

Signatures

```
GEOMETRY ST_CoverageSimplify_Agg (col0 GEOMETRY, col1 DOUBLE)
GEOMETRY ST_CoverageSimplify_Agg (col0 GEOMETRY, col1 DOUBLE, col2 BOOLEAN)
```

Description Simplifies a set of geometries while maintaining coverage

---

ST_CoverageUnion_Agg

Signature

```
